Introduction to XYZ States
What are XYZ States?

Below open charm threshold
- Good agreement between prediction and observation

Above open charm threshold
- Expected states missing
- Unexpected states observed (→ XYZ States)

X Neutral, other than 1
Y Neutral, 1
Z Charged
Possible Explanations

- **Tetraquark**: Compact four quark state made from colored \((Qq)\) and \((\bar{Q}\bar{q})\)
- **Hybrid**: \(Q\bar{Q}\) with exited gluon
- **Hadro-Quarkonium**: \(Q\bar{Q}\) in cloud of light quarks
- **Glueball**: State only from gluons
- **Meson-Molecule**: Two mesons bound by residual forces \((Q\bar{q})\) and \((\bar{Q}q)\)
- **Threshold Effect**
- ... Any new ideas?
A SCHEMATIC MODEL OF BARYONS AND MESONS *

M. GELL-MANN
California Institute of Technology, Pasadena, California

Received 4 January 1964

If we assume that the strong interactions of baryons and mesons are correctly described in terms of the broken "eightfold way" 1-3, we are tempted to look for some fundamental explanation of the situation. A highly promised approach is the purely dynamical "bootstrap" model for all the strongly interacting particles within which one may try to derive isotopic spin and strangeness conservation and broken eightfold symmetry from self-consistency alone 4. Of course, with only strong interactions, the orientation of the asymmetry in the unitary space cannot be specified; one hopes that in some way the selection of specific components of the F-spin by electromagnetism and the weak interactions determines the choice of isotopic spin and hypercharge directions.

Even if we consider the scattering amplitudes of strongly interacting particles on the mass shell only and treat the matrix elements of the weak, electromagnetic, and gravitational interactions by means of $n_t - n_f$ would be zero for all known baryons and mesons. The most interesting example of such a model is one in which the triplet has spin $\frac{1}{2}$ and $z = -1$, so that the four particles $d^\ast$, $s^\ast$, $u^0$ and $b^0$ exhibit a parallel with the leptons.

A simpler and more elegant scheme can be constructed if we allow non-integral values for the charges. We can dispense entirely with the basic baryon $b$ if we assign to the triplet $t$ the following properties: spin $\frac{1}{2}$, $z = -\frac{1}{3}$, and baryon number $\frac{1}{3}$. We then refer to the members $u^\ast$, $d^\ast$, and $s^\ast$ of the triplet as "quarks" $q$ and the members of the anti-triplet as anti-quarks $q$. Baryons can now be constructed from quarks by using the combinations $(qqq)$, $(qqqqq)$, etc., while mesons are made out of $(q\bar{q})$, $(qq\bar{q})$, etc. It is assuming that the lowest baryon configuration $(qqq)$ gives just the representations 1, 8, and 10 that have been observed, while the lowest meson configuration $(qq)$ similarly gives just 1 and 8.

**BESIII: Two resonances!** (PRL 118, 092001 (2017))

- Coherent sum of two BWs + incoherent \( \psi(3770) \)
  - Fit I: + coherent 3\(^{rd}\) BW, Fit II: + exponential
  - \( M_1 = (4222.0 \pm 3.1 \pm 1.4) \text{ MeV}, \Gamma_1 = (44.1 \pm 4.3 \pm 2.0) \text{ MeV} \)
    - lower and narrower than previous \( Y(4260) \) PDG value
  - \( M_2 = (4320.0 \pm 10.4 \pm 7.0) \text{ MeV}, \Gamma_2 = (101.4^{+25.3}_{-19.7} \pm 10.2) \text{ MeV} \)
    - a little bit lower than \( Y(4360) \) PDG value
  - Significance of double BW vs. single BW > 7.6 \( \sigma \)
$e^+ e^- \rightarrow \pi^+ \pi^- h_c$ Cross Section

**PRL 118, 092002 (2017)**

- $h_c$ reconstructed in $h_c \rightarrow \gamma \eta_c$, $\eta_c \rightarrow 16$ exclusive hadronic final states
- Coherent sum of two BWs
  - $M_1 = (4218.4^{+5.5}_{-4.5} \pm 0.9)$ MeV, $\Gamma_1 = (66.0^{+12.3}_{-8.3} \pm 0.4)$ MeV
  - $M_2 = (4391.5^{+6.3}_{-6.8} \pm 1.0)$ MeV, $\Gamma_2 = (139.5^{+16.2}_{-20.6} \pm 0.6)$ MeV
- First one has consistent mass with $\pi^+ \pi^- J/\psi$ state at 4222 MeV
- Significance of double BW vs. single BW is $10 \sigma$
$e^+e^- \rightarrow \pi\pi\psi'$ Cross Section

$e^+e^- \rightarrow \pi^+\pi^-\psi'$

**PRD 96, 032004 (2017)**

- Clear peak around $Y(4360)$, consistent with results from Belle and BaBar
- Fit with three resonances: $Y(4220)$, $Y(4390)$, $Y(4660)$
- $Y(4220)$ significance is 5.8 $\sigma$

$e^+e^- \rightarrow \pi^0\pi^0\psi'$

**PRD 97, 052001 (2018)**

- Cross section consistent with isospin expectations from $\pi^+\pi^-\psi'$
$e^+ e^- \rightarrow KKJ/\psi$ Cross Section

- black: high statistics data
- gray: low statistics data

PRD 97, 071101(R) (2018)

- Different lineshape than $\pi^+ \pi^- J/\psi$
- Evidence for a structure around 4.5 GeV
- Charged and neutral mode consistent with isospin expectations
$e^+e^- \rightarrow \eta h_c$ Cross Section

PRD 96, 012001 (2017)

- $h_c$ reconstructed in $h_c \rightarrow \gamma \eta_c, \eta_c \rightarrow 16$ exclusive hadronic final states

- Clear signals at 4.226 GeV and evidence at 4.358 GeV

- Fit with three BWs only for calculation of radiative correction factors
$e^+ e^- \rightarrow \pi^+ D^0 D^{*-} + \text{c.c.}$ Cross Section

- Fit with three-body phase space and two BWs hadronic final states

- $M_1 = (4228.6 \pm 4.1 \pm 5.0)$ MeV, $\Gamma_1 = (77.1 \pm 6.8 \pm 2.7)$ MeV
- $M_1 = (4404.6 \pm 7.4 \pm 4.8)$ MeV, $\Gamma_1 = (192 \pm 13 \pm 15)$ MeV
- Both masses consistent with those in $\pi^+ \pi^- h_c$ and $\pi^+ \pi^- \psi'$
"Y(4260)" in the Light of High Luminosity Measurements

by Ryan Mitchell
Conclusion

Summary
- Lots of progress in exotic charmonium-like studies
- Many cross section lineshapes measured
- $Y(4260) \rightarrow Y(4220)$, seen in many final states

Outlook
- More data expected within next few years (high statistics scan between $\approx 4.2$ and $\approx 4.4$ GeV)
- Machine upgrade approved ($\sqrt{s}$ up to 4.9 GeV + top up injection)

Thank You!
$X(3872)$ at BESIII

2014

\[ e^+e^- \rightarrow \gamma X(3872) \text{ with } X(3872) \rightarrow \pi^+\pi^-J/\psi \]

PRL 119, 072001 (2017)
$e^+ e^- \rightarrow \Lambda_c \bar{\Lambda}_c$

**BESIII**  Ablikim *et al.*, arXiv:1710.00150 [hep-ex].
\[ e^+ e^- \rightarrow \Lambda_c \bar{\Lambda}_c \]

- The BESIII measurements indicate that:
  - At thr there is indeed a jump in \( \sigma(e^+ e^- \rightarrow \Lambda_c \ \Lambda_{cbar}) \),
  - Followed by a kind of a plateau
  - At thr \( \sigma(e^+ e^- \rightarrow \Lambda_c \ \Lambda_{cbar}) \) is close to the pointlike value, once the Coulomb enhancement factor is taken into account:
    \[ \sigma(e^+ e^- \rightarrow \Lambda_c \ \Lambda_{cbar})_{\text{pointl}} \approx \pi^2 \alpha^3/(2M_B) \approx 145 \text{ pb} \]
  - Qualitatively, If \( \sigma(e^+ e^- \rightarrow BB_{\bar{\text{bar}}}) \) would be driven by strong interaction, [asymptotically scaling as \((M_\rho / M_{\Lambda_c})^{10}\) ] a quite smaller value (< 1 fb) would be expected [ \( \sigma(e^+ e^- \rightarrow pp_{\bar{\text{bar}}}) \approx 0.85 \text{ nb, at thr} \).]
$e^+ e^- \rightarrow \Lambda_c \bar{\Lambda}_c$

- The angular distr. is almost flat, as expected, at $W = 4.57$ GeV ($\beta_{\Lambda_c} = 0.026$) within the errors. By the way very close to $\pi \alpha = 0.023$, where Coulomb should matter.

- The collected statistics is quite high at $W = 4.60$ GeV ($\beta_{\Lambda_c} = 0.11$) and as already seen in $e^+ e^- \rightarrow p \bar{p}_{\text{bar}}$ at $W = 1.91$ GeV ($\beta_p = 0.20$), there is a very early onset of the D wave.
$G_E(q^2)/G_M(q^2)$: D wave at thr or early onset?

- $R(q^2) = G_E(q^2)/G_M(q^2)$

- Present data on $R(q^2)$ (in the case of BaBar unfortunately integrated on a too large $Q^2$ interval) indicate that $G_D(q^2)$ seems not vanishing, close to thr:
  
  $G_D(q^2) \neq 0 \quad q^2 \approx 4M_B^2$?
BESIII versus Belle in $e^+ e^- \rightarrow \Lambda_c \Lambda_{c\bar{c}}$

- Not settled yet, since there is some tension between BESIII and Belle in $\sigma(e^+ e^- \rightarrow \Lambda_c \Lambda_{c\bar{c}})$, as pointed out by Ulf Meissner and his collaborators and shown in the following,
  in particular:

  - Belle data show a wide resonance, consistent with the $Y(4660)$, seen by BaBar and Belle in $e^+ e^- \rightarrow \psi(3686) \pi^+ \pi^-$, hardly compatible with BESIII flat behaviour up to 4.6 GeV.

  - Belle data are fit by means of a resonance on top of $\Lambda_c \Lambda_{c\bar{c}}$ FSI, that predicts again a fast rise at thr, but not a jump.

  - More data at thr and above are needed and BESIII already got funds to increase maximum energy up to $W = 4.9$ GeV.
Fit to Belle Measurements

- Ling-Yun Dai, Johann Haidenbauer, Ulf-G. Meißner

- Resonance $Y(4660)$ [called $X(4660)$ in this paper] + FSI @thr:
  $M = (4652.5 \pm 3.4)$ MeV
  $\Gamma = (62.6 \pm 5.6)$ MeV
  $\sigma_{\text{peak}} \sim 0.55$ nb [comparable to $\sigma(e^+ e^- \rightarrow p\bar{p}_{\text{bar}}) \sim 0.8$ nb @ threshold]

- Concerning BESIII measurements they write:
  "While they agree with the Belle data, as for as cross sections magnitude, they indicate a different trend in energy.
  It is impossible to fit both data.
  Hopefully BESIII will extend their measurements at higher energies and thereby clarify the situation."

Our Friend Ulf Meissner
IHEP, 2018 May 31st
Other evidences of the Y(4660)

\( e^+ e^- \to \psi(3686) \pi^+ \pi^- \) by means of ISR

BaBar

\[ M = 4669 \pm 22, \quad \Gamma = 104 \pm 49 \]

PHYSICAL REVIEW D 89, 111103(R) (2014)

Belle

\[ M = 4652 \pm 13, \quad \Gamma = 68 \pm 11 \]

PHYSICAL REVIEW D 91, 112007 (2015)
**Y(4660) in $e^+e^- \rightarrow \psi(3686) \pi \pi$ cross section**

- $M = (4667 \pm 7) \text{ MeV}$
- $\Gamma = [36+32 (-14)] \text{ MeV}$ (updated in PDG: $72 \pm 11 \text{ MeV}$)
- $B\Gamma_{ee} = (1.4 \pm 0.5) \text{ eV}$

- $\sigma_{\text{peak}} = 12\pi/M^2 B\Gamma_{ee} / \Gamma \times 1.5(\text{incl } \pi^0 \pi^0) \sim 0.04 \pm 0.025 \text{ nb}$
  consistent with BaBar cross section $\sim 30 \times 1.5 \text{ n}$

  to be compared to $e^+e^- \rightarrow \Lambda_c \Lambda_{c\bar{c}} \sigma_{\text{peak}} \sim 0.55 \text{ nb}$

- **Y(4660) baryonic coupling $\geq 10$ mesonic coupling**
  Unexpected!

  There is another mesonic decay with much larger BR than $\psi(3686) \pi \pi$?

  or

  **Y(4660) is a Hidden charm baryonium?**
Y(4660) Charmed Baryonium?

- The decay $Y(4660) \rightarrow J/\psi \pi\pi$ would be expected to be large if it is a $c\bar{c}$ state, while at 90% C.L.

$$\text{BR}[Y(4660) \rightarrow J/\psi \pi\pi] / \text{BR}[Y(4660) \rightarrow \psi(3686) \pi\pi] < 0.46,$$

$$e^+ e^- \rightarrow J/\psi \pi^+ \pi^-$$
Y(4660) Charmed Baryonium?

  
  [see also L. Maiani, F. Piccinini, A. D. Polosa and V. Riquer, Phys. Rev. D 72, 031502]  
  Y(4660) fulfills the old Rossi Veneziano, G.F. Chew paradigm
  

of a charm tetraquark (hidden charm baryonium) decay: mostly poping up from the vacuum a light quark pair and falling apart as a charmed baryon pair.
Y(4660) Charmed Baryonium?

- Y(4660) mass, close to the $\Lambda_c \Lambda_{c\bar{c}}$ threshold, is in favour of its interpretation as a charmed baryonium.

- $Y(4660) \rightarrow \Lambda_c \Lambda_{c\bar{c}}$ shape and width, actually (expected large, according to the Rossi Veneziano model) is constrained by the threshold close by.

- If BESIII would not confirm the $Y(4660) \rightarrow \Lambda_c \Lambda_{c\bar{c}}$ decay a strong support of the interpretation of the XYZ states as tetraquark states would be somewhat in trouble.

- It might be that the Meissner et al conclusions are too drastic. In the following slide a fit with a $Y(4660)$ on top of a Coulomb amplitude closer to a pointlike $\Lambda_c \Lambda_{c\bar{c}}$ at threshold is shown. More data by BESIII at threshold and above $W=4.6$ GeV will settle all these questions.
Try to fit by means of a simple model
Belle + BESIII data

- Belle+ BESIII: $M = 4644 \pm 6 \text{ MeV}$, $\Gamma = 80 \pm 17 \text{ MeV}$, $P = 63 \%$
