TEORIA SIMMETRICA DELL'ELETTRONE E DEL POSITRONE

Nota di ETTORE MAJORANA

Symmetric Theory of Electron and Positron Nuovo Cim. 14 (1937) 171

Sunto. - Si dimostra la possibilità di pervenire a una piena simmetrizzazione formale della teoria quantistica dell'elettrone e del positrone facendo uso di un nuovo processo di quantizzazione. Il significato delle equazioni di DIRAC ne risulta alquanto modificato e non vi è più luogo a parlare di stati di energia negativa; nè a presumere per ogni altro tipo di particelle, particolarmente neutre, l'esistenza di « antiparticelle » corrispondenti ai « vuoti » di energia negativa.

L'interpretazione dei cosidetti « stati di energia negativa » proposta da DIRAC (¹) conduce, come è ben noto, a una descrizione sostanzialmente simmetrica degli elettroni e dei positroni. La sostanziale simmetria del formalismo consiste precisamente in questo, che fin dove è possibile applicare la teoria girando le difficoltà di convergenza, essa fornisce realmente risultati del tutto simmetrici. Tuttavia gli artifici suggeriti per dare alla teoria una forma simmetrica

isfacenti; trica, sia iante tali :he possinuova via

che conduce più direttamente alla meta.

Per quanto riguarda gli elettroni e i positroni, da essa si può veramente attendere soltanto un progresso formale; ma ci sembra importante, per le possibili estensioni analogiche, che venga a cadere la nozione stessa di stato di energia negativa. Vedremo infatti che è perfettamente possibile costruire, nella maniera più naturale, una teoria delle particelle neutre elementari senza stati negativi.

It follows from the above assumptions that in vacuum a neutrino can be transformed into an antineutrino and vice versa. This means that the neutrino and antineutrino are "mixed" particles, i.e., a symmetric and antisymmetric combination of two truly neutral Majorana particles ν_1 and ν_2 of different combined parity.⁵

1968 Gribov, Pontecorvo [PLB 28(1969) 493] oscillations of neutrinos - a solution of deficit of solar neutrinos in Homestake exp.

OUTLINE

- Introduction v-oscillations and v-masses
- The 0vbb-decay scenarios due neutrinos exchange (simpliest, sterile v, LR-symmetric model)
- **DBD** NMEs and Quenching of g_A (nuclear structure issues)
- DBD with emission of a single electron
- DBD NMEs within schematic models (SU(4) symmetry, nonlinear QRPA)

• Conclusion

mass-squared differences: $\Delta m^2_{SUN} \cong 7.5 \ 10^{-5} \ eV^2$, $\Delta m^2_{ATM} \cong 2.4 \ 10^{-3} \ eV^2$

The observed small neutrino masses (limits from tritium β-decay, cosmology) have profound implications for our understanding of the Universe and are now a major focus in astro, particle and nuclear physics and in cosmology.

The answer to the question whether neutrinos are their own antiparticles is of central importance, not only to our understanding of neutrinos, but also to our understanding of the origin of mass.

What is the nature of neutrinos?

Symmetric Theory of Electron and Positron Nuovo Cim. 14 (1937) 171

Only the $0\nu\beta\beta$ -decay can answer this fundamental question

Analogy with kaons: K₀ and K₀

Fedor Simkovic

Analogy with π_0

Beyond the Standard model physics (EFT scenario)

Minimal SM + EFT

The absence of the right-handed neutrino fields in the Standard Model is the simplest, most economical possibility. In such a scenario Majorana mass term is the only possibility for neutrinos to be massive and mixed. This mass term is generated by the lepton number violating Weinberg effective Lagrangian.

$$\mathcal{L}_{5}^{eff} = -\frac{1}{\Lambda} \sum_{l_{1}l_{2}} \left(\overline{\Psi}_{l_{1}L}^{lep} \widetilde{\Phi} \right) \acute{Y}_{l_{1}l_{2}} \left(\widetilde{\Phi}^{T} (\Psi_{l_{2}L}^{lep})^{e} \right)$$
$$m_{i} = \frac{v}{\Gamma} (y_{i}v), \quad i = 1, 2, 3 \qquad \Lambda > 10^{15} \text{ GeV}$$

Heavy Majorana leptons $N_i (N_i=N_i^c)$ singlet of $SU(2)_L xU(1)_Y$ group Yukawa lepton number violating int.

The three Majorana neutrino masses are suppressed by the ratio of the electroweak scale and a scale of a lepton-number violating physics.

The discovery of the $\beta\beta$ -decay and absence of transitions of flavor neutrinos into sterile states would be evidence in favor of this minimal scenario.

NMEs for unquenched value of g_A

Mean field approaches (PHFB, NREDF, REDF) ⇒ Large NMEs

Interacting Shell Model (ISM-StMa, ISM-CMU) ⇒ small NMEs

Quasiparticle Random Phase Approximation (QRPA-TBC, QRPA-Jy, dQRPQ-NC) ⇒ Intermediate NMEs

Interacting Boson Model (IBM) ⇒ Close to QRPA results

J.D.Vergados, H. Ejiri, , F.Š., Int. J. Mod. Phys. E25, 1630007(2016)

Quenching of g_A

$g_{A}^{4} = (1.269)^{4} = 2.6$ Quenching of g_{A} (from exp.: $T_{1/2}^{0\nu}$ up 2.5 x larger) Strength of GT trans. (approx. given by Ikeda sum rule =3(N-Z)) $(g^{eff}{}_{A})^{4} = 1.0$ has to be quenched to reproduce experiment 25 $_{\Box}$ $^{76}_{32}\text{Ge}_{44} \Rightarrow$ standard QRPA $S_{\beta}^{-} - S_{\beta}^{+} = 3(N-Z) = 36$ exp. via (p,n) reaction 20 exp. via (³He,t) reaction $\langle 1_m^+ | \beta_{GT}^- | RPA \rangle |^2$ (4) transition virtual 5 76_{Ge} ⁷⁶As 76_{Se} 0 **Pauli blocking** 8 10 12 18 6 14 16 20E [MeV] **Cross-section for charge exchange reaction:** $\left[\frac{d\sigma}{d\Omega}\right] = \left[\frac{\mu}{\pi\hbar}\right]^2 \frac{k_f}{k} \operatorname{Nd} \left|V_{\sigma\tau}\right|^2 \left|\langle f | \sigma\tau| i\rangle\right|^2$ q = 0!!p n n largest at 100 - 200 MeV/A

Quenching of g_A (from theory: $T_{1/2}^{0\nu}$ up 50 x larger)

 $(g^{eff}_{A})^4 \simeq 0.66 (^{48}Ca), 0.66 (^{76}Ge), 0.30 (^{76}Se), 0.20 (^{130}Te) and 0.11 (^{136}Xe)$ The Interacting Shell Model (ISM), which describes qualitatively well energy spectra, does reproduce experimental values of $M^{2\nu}$ only by consideration of significant quenching of the Gamow-Teller operator, typically by 0.45 to 70%.

(g^{eff}_A)⁴ ≃ (1.269 A^{-0.18})4 = 0.063 (The Interacting Boson Model). This is an incredible result. The quenching of the axial-vector coupling within the IBM-2 is more like 60%.
 J. Barea, J. Kotila, F. Iachello, PRC 87, 014315 (2013).

It has been determined by theoretical prediction for the 2vββ-decay half-lives, which were based on within closure approximation calculated corresponding NMEs, with the measured half-lives.

Faessler, Fogli, Lisi, Rodin, Rotunno, F. Š, J. Phys. G 35, 075104 (2008).

 $(g^{eff}{}_{A})^{4} = 0.30$ and 0.50 for ¹⁰⁰Mo and ¹¹⁶Cd, respectively (The QRPA prediction). $g^{eff}{}_{A}$ was treated as a completely free parameter alongside g_{pp} (used to renormalize particl-particle interaction) by performing calculations within the QRPA and RQRPA. It was found that a least-squares fit of $g^{eff}{}_{A}$ and g_{pp} , where possible, to the β -decay rate and β +/EC rate of the J = 1⁺ ground state in the intermediate nuclei involved in double-beta decay in addition to the $2\nu\beta\beta$ rates of the initial nuclei, leads to an effective $g^{eff}{}_{A}$ of about 0.7 or 0.8.

A novel method to determine effective g_A

F. Š., R. Dvornický, D. Štefánik, A. Faessler, to be submitted

Fedor Simkovic

Improved description of the 0νββ**–decay rate**

$$M_{GT}^{K,L} = m_e \sum_n M_n \frac{E_n - (E_i + E_f)/2}{[E_n - (E_i + E_f)/2]^2 - \varepsilon_{K,L}^2}$$

Let perform Taylor expansion

$$\frac{\varepsilon_{K,L}}{E_n - (E_i + E_f)/2} \quad \epsilon_{K,L} \in \left(-\frac{Q}{2}, \frac{Q}{2}\right)$$

We get

$$\left[T_{1/2}^{2\nu\beta\beta}\right]^{-1} \simeq \left(g_A^{\text{eff}}\right)^4 \left|M_{GT-3}^{2\nu}\right|^2 \frac{1}{\left|\xi_{13}^{2\nu}\right|^2} \left(G_0^{2\nu} + \xi_{13}^{2\nu}G_2^{2\nu}\right)$$

$$M_{GT-1}^{2\nu} = \sum_{n} M_{n} \frac{1}{(E_{n} - (E_{i} + E_{f})/2)}$$
$$M_{GT-3}^{2\nu} = \sum_{n} M_{n} \frac{4 m_{e}^{3}}{(E_{n} - (E_{i} + E_{f})/2)^{3}} \qquad \xi_{13}^{2\nu} = \frac{M_{GT-3}^{2\nu}}{M_{GT-1}^{2\nu}}$$

The g_A^{eff} can be deterimed with measured half-life and ratio of NMEs and calculated NME dominated by transitions through low lying states of the intermediate nucleus (ISM?)

The running sum of the $2\nu\beta\beta$ -decay NMEs

Normalized to unity different partial energy distributions

ξ_{13} tell us about importance of higher lying states of int. nucl.

Double beta decay with emission of a single electron

Double Beta Decay with emission of a single electron

A. Babič, M.I. Krivoruchenko, F.Š., tobe submitted to PRC

[Jung *et al.* (GSI), 1992] observed beta decay of ${}^{163}_{66}$ Dy⁶⁶⁺ ions with Electron Production (EP) in K or L shells: $T^{EP}_{1/2} = 47$ d

Bound-state double-beta decay $0\nu EP\beta^-$ ($2\nu EP\beta^-$) with EP in available $s_{1/2}$ or $p_{1/2}$ subshell of daughter 2+ ion:

Search for possible manifestation in single-electron spectra...

48

$0\nu EP\beta^{-}$ Single-Electron Spectrum (⁸²Se)

 $0\nu\beta^{-}\beta^{-}$ and $0\nu EP\beta^{-}$ single-electron spectra $1/\Gamma^{0\nu\beta\beta} d\Gamma/dE$ vs. electron kinetic energy $E - m_e$ for ⁸²Se (Q = 2.996 MeV)

$0\nu EP\beta^-$ Half-Lives

 $0\nu\beta^{-}\beta^{-}$ and $0\nu EP\beta^{-}$ half-lives $T_{1/2}^{0\nu\beta\beta}$ and $T_{1/2}^{0\nu EP\beta}$ estimated for $\beta^{-}\beta^{-}$ isotopes with known NME $|M^{0\nu\beta\beta}|$, assuming unquenched $g_{A} = 1.269$ and $|m_{\beta\beta}| = 50 \text{ meV}$

$2\nu EP\beta^{-}$ Single-Electron Spectrum (⁸²Se)

 $2\nu\beta^{-}\beta^{-}$ and $2\nu EP\beta^{-}$ single-electron spectra $1/\Gamma d\Gamma/dE$ vs. electron kinetic energy $E - m_e$ for ⁸²Se (Q = 2.996 MeV)

$2\nu EP\beta^{-}$ Half-Lives predictions (independent on g_A and value of NME)

 $2\nu\beta^{-}\beta^{-}$ and $2\nu EP\beta^{-}$ half-lives $T_{1/2}^{2\nu\beta\beta}$ and $T_{1/2}^{2\nu EP\beta}$ calculated for $\beta^{-}\beta^{-}$ isotopes observed experimentally, assuming unquenched $g_{A} = 1.269$

Nuclear structure studies within schematic models

Understanding of the $2\nu\beta\beta$ -decay NMEs is of crucial importance for correct evaluation of the $2\nu\beta\beta$ -decay NMEs

 $(A,Z) \rightarrow (A,Z+2) + 2e^- + 2\overline{\nu}_e$

Both 2νββ and 0νββ operators connect the same states. Both change two neutrons into two protons.

Explaining $2\nu\beta\beta$ -decay is necessary but not sufficient

There is no reliable calculation of the 2vbb-decay NMEs

Calculation via intermediate nuclear states: **QRPA** (sensitivity to pp-int.) **ISM** (quenching, truncation of model space, spin-orbit partners)

Calculation via closure NME: IBM, PHFB

No calculation: EDF
