Introduction

- Signatures of collective behavior are observed in azimuthal harmonics v_n even in small systems (pp and $p+Pb$).
- Collectivity can be probed by measuring the geometry of particle production (e.g. in collective expansion, the freeze-out size decreases with rising k_T).
- The freeze-out source can be probed through the 2-particle correlation function

$$C_k(q) = \int d^3r S_k(r) |\psi_q(r)|^2, \quad (1)$$

where $k = (p_1 + p_2)/2$ is the average pair momentum and $q = (p_1 - p_2)$ is the relative momentum.

- $C_k(q)$ is fit to a function to get length scales of $S_k(r)$, which are referred to as the *HBT radii*.

- The experimental correlation function is

$$C(q) = [1 - \lambda + \lambda K(q) C_{BE}(q)] \Omega(q), \quad (2)$$

where K is the Coulomb correction, C_{BE} is the Bose-Einstein correlation, and Ω represents background correlations.

- use "out-side-long" coordinate system

q_{out} : along k_T

q_{side} : other transverse component

q_{long} : longitudinal component in longitudinal rest frame of pair

- The 3D BE correlation is fit to a function of the form

$$C_{BE}(\mathbf{q}) = 1 + e^{-\|\mathbf{R}\mathbf{q}\|}, \quad (3)$$

where R is a symmetric matrix

$$R = \begin{pmatrix} R_{out} & R_{os} & R_{ol} \\ R_{os} & R_{side} & 0 \\ R_{ol} & 0 & R_{long} \end{pmatrix}$$

with $R_{ol} \neq 0$ in the rapidity-dependent analysis and $R_{os} \neq 0$ in the azimuthal analysis.

Pion identification

- The wavefunction in Eqn. 1 has particularly good resolving power if there is BE enhancement.
- Identical pions are identified using ionization energy loss in pixel clusters.

Figure 1: The pion pair purity as a function of k_T and rapidity $y_{\pi\pi}^*$.

Jet fragmentation background

- The presence of hard processes in the collisions causes correlations to arise from the mini-jet fragmentation.
- The relationship between same-charge and opposite-charge jet correlations is studied in PYTHIAS.
- The opposite-charge data is used to constrain the same-sign jet contribution.

Figure 2: The opposite-charge data (teal) is fit to a function (blue dashed). The parameters of this fit are used to fix the fragmentation description (violet dotted) in the same-charge data (red). The remaining parameters are fit to the same-charge data (dark red line).

Results

Example fit

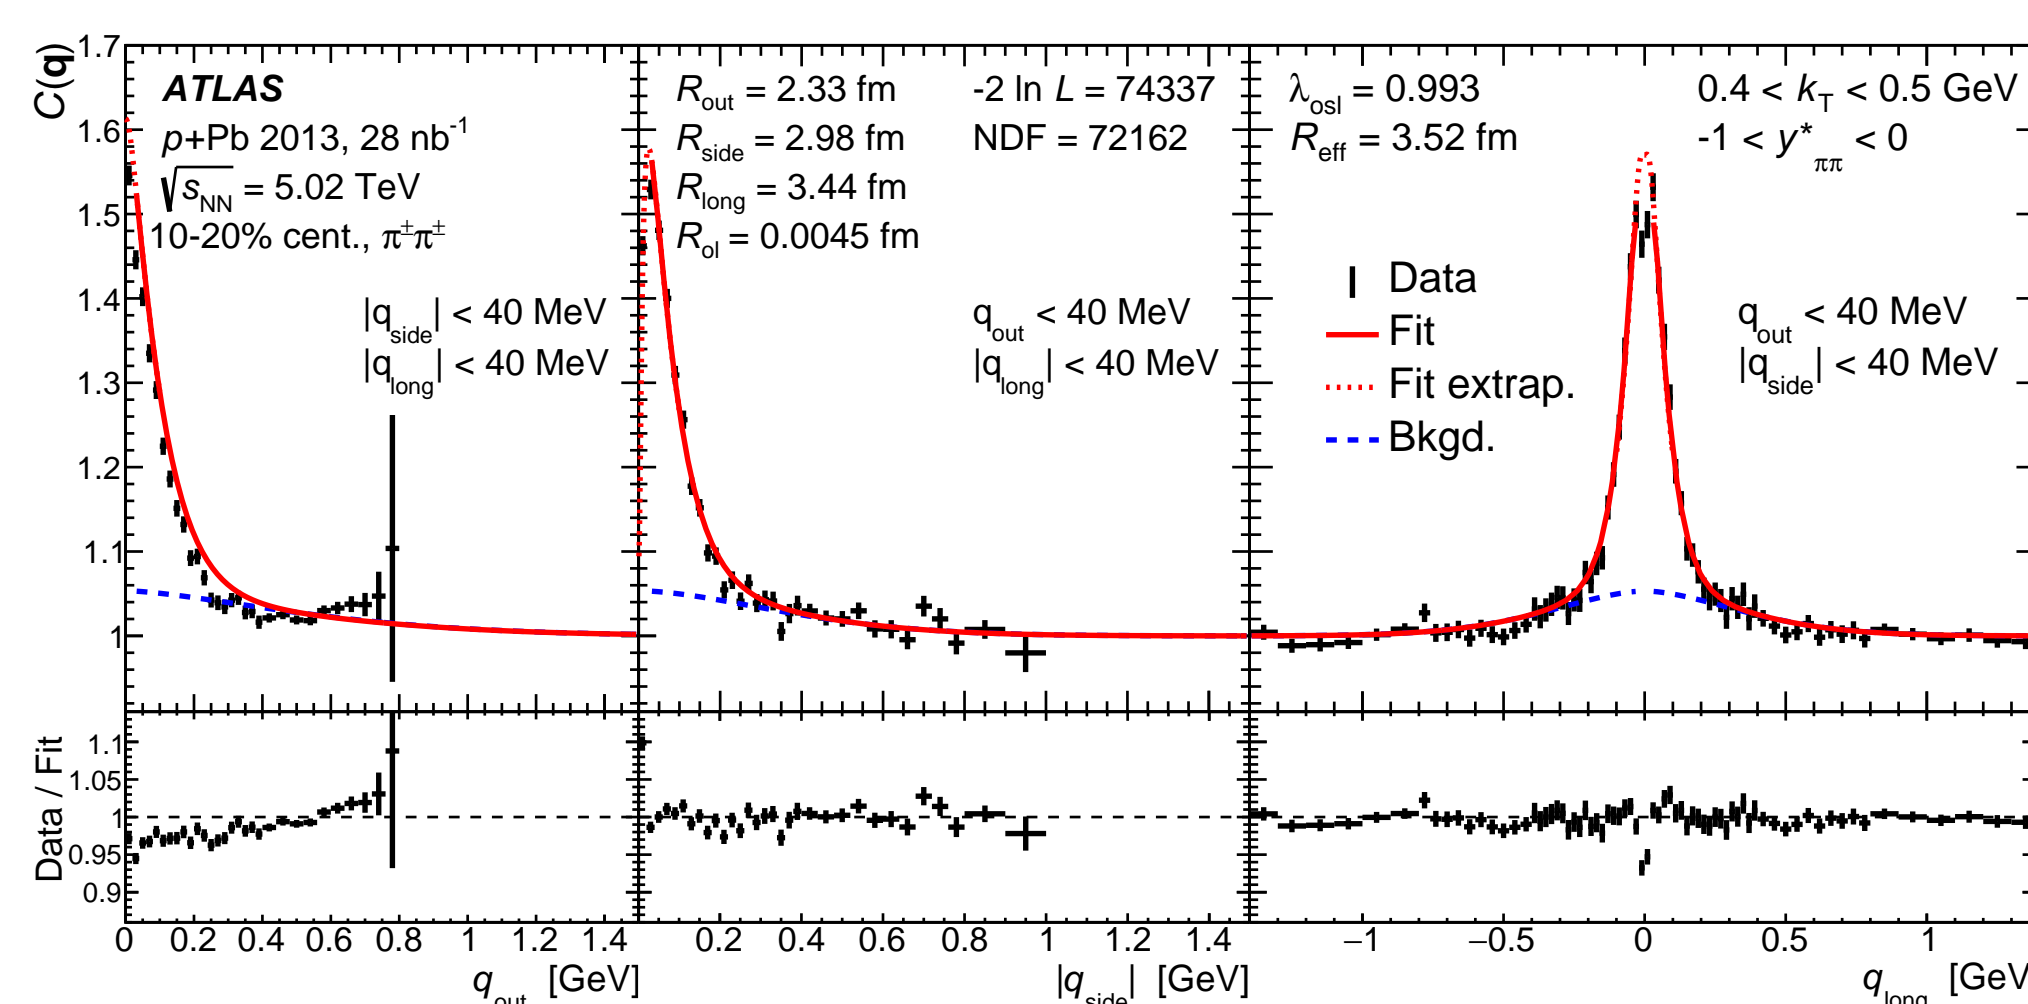

Figure 3: An example 3D fit along each q -axis.

Main HBT radii as function of k_T , $y_{\pi\pi}^*$, and multiplicity

Figure 4: The transverse HBT radii R_{out} (left), R_{side} (right) as a function of pair transverse momentum k_T .

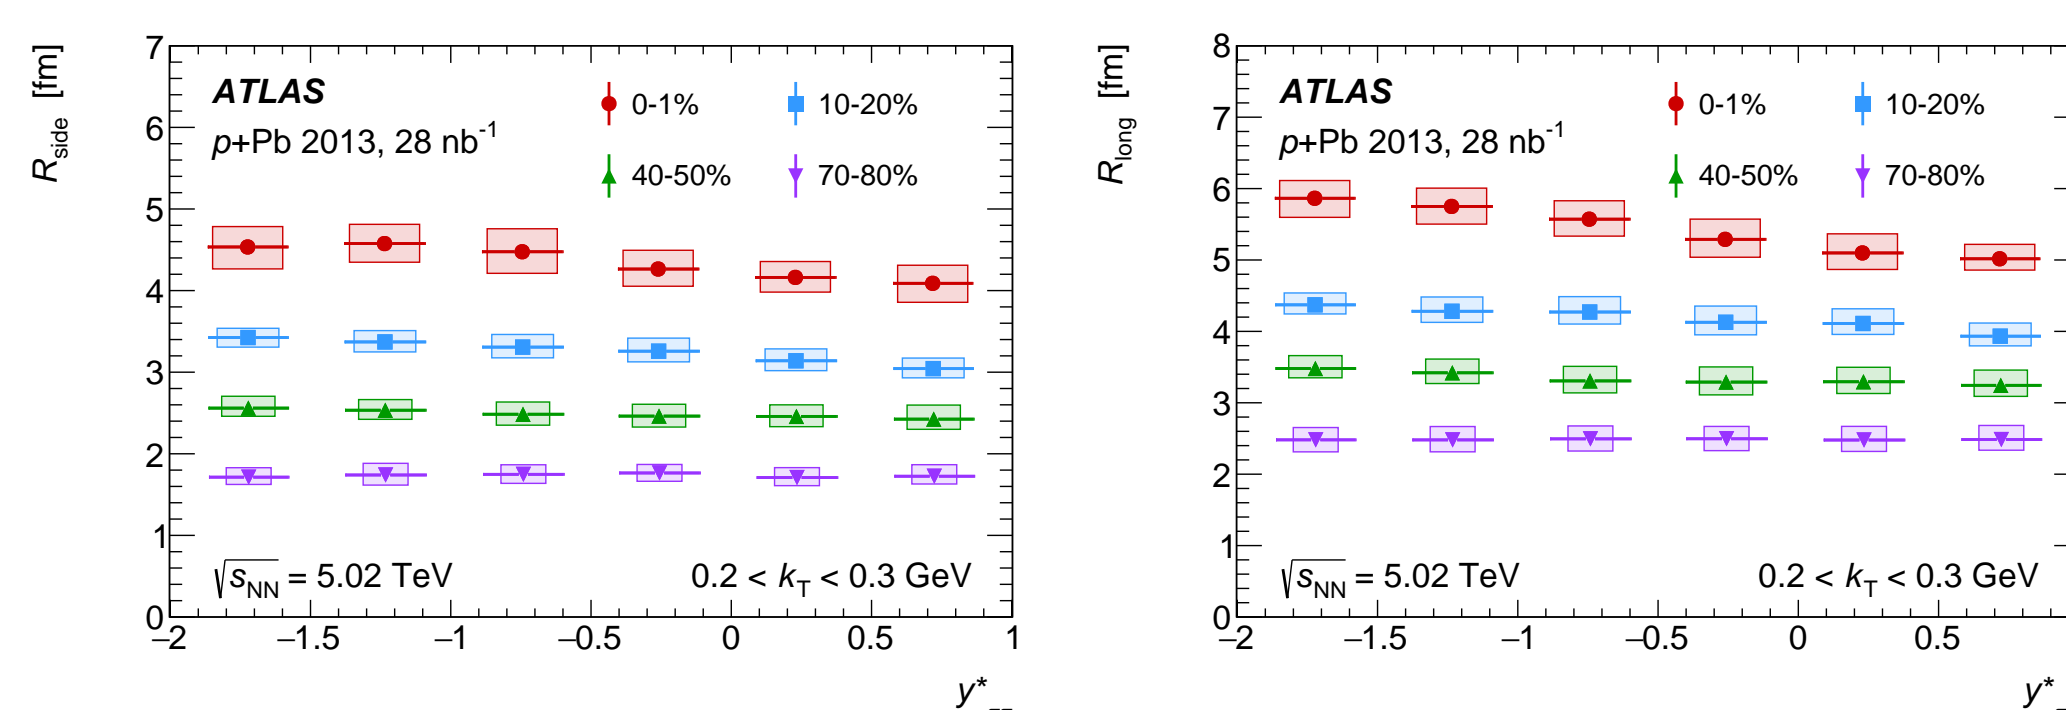

Figure 5: The HBT radii R_{side} (left), and R_{long} (right) as a function of pair rapidity $y_{\pi\pi}^*$.

Figure 6: The HBT radii R_{out} (left) and R_{long} (right) as a function of local multiplicity dN_{ch}/dy^* .

Combinations and off-diagonal radii

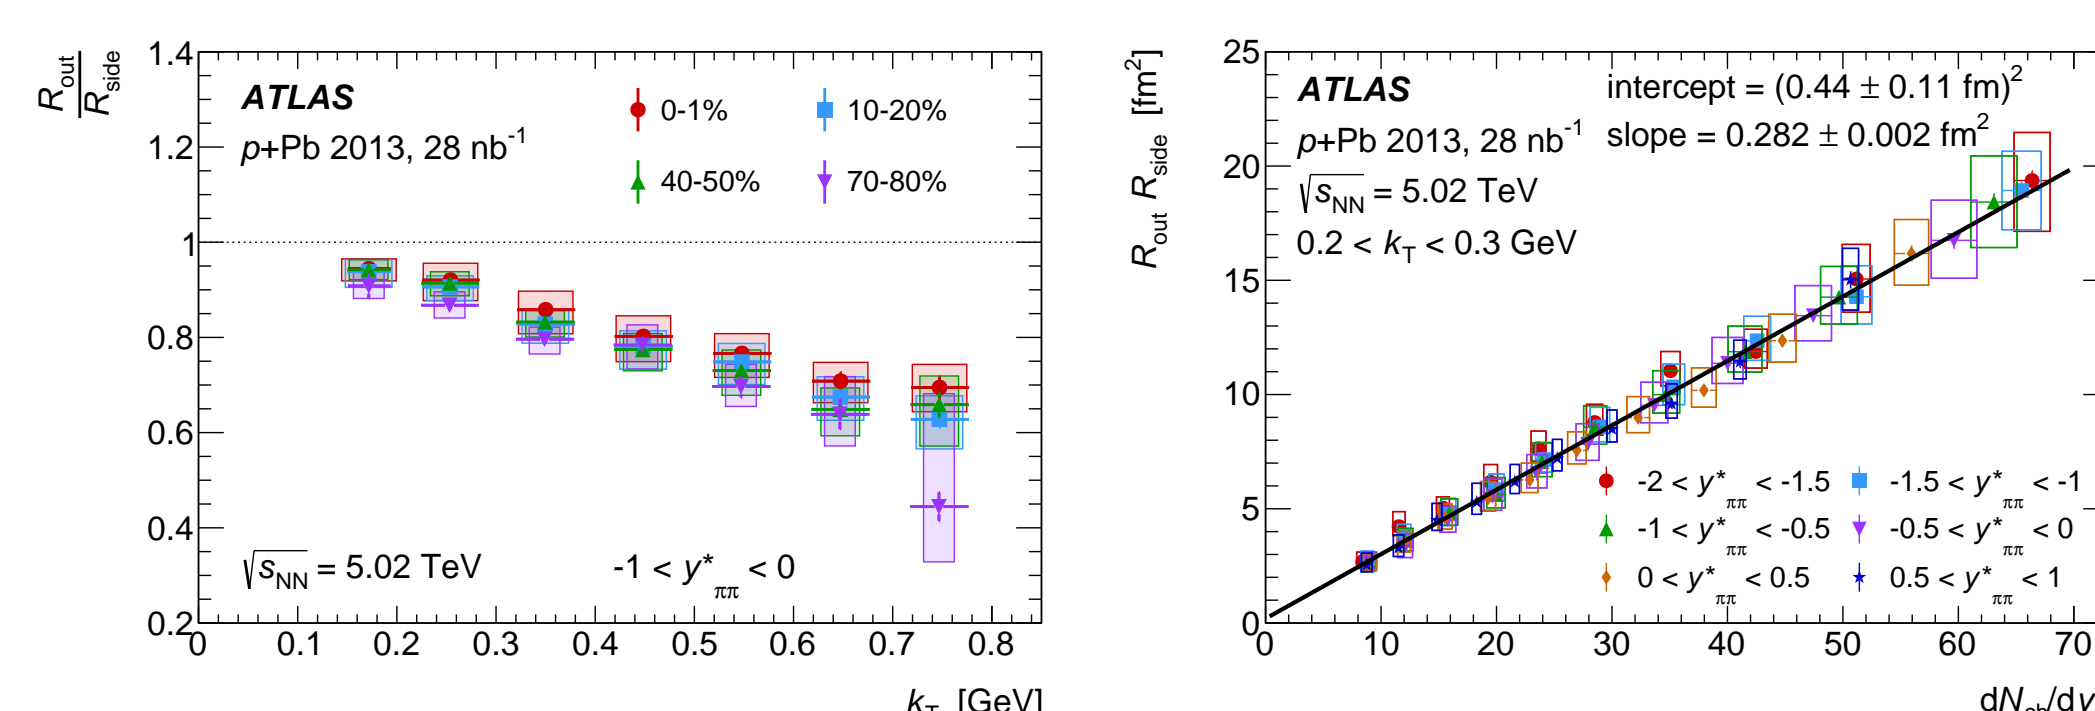

Figure 7: The ratio R_{out}/R_{side} (left) indicates the explosiveness of the event, because R_{out} couples directly to the lifetime while R_{side} does not. At low k_T the transverse area element $R_{out}R_{side}$ (right) scales linearly with multiplicity, indicating constant transverse area density.

Figure 8: The cross-term R_{01} is observed to be distinct from 0 in the proton-going side of central events, with a combined significance of 5.1σ at $-1 < y_{\pi\pi}^* < -1$ in the 0-1% centrality interval. This indicates longitudinal and transverse expansion and a breaking of boost invariance.

Azimuthal dependence

The correlation functions are measured in intervals of azimuthal angle ϕ_k with respect to the 2nd-order event plane Ψ_2 . The main-diagonal HBT radii are fit to a function which allows extraction of their 2nd-order Fourier coefficients,

$$R_i = R_{i,0} + 2R_{i,2} \cos[2(\phi_k - \Psi_2)]. \quad (4)$$

Figure 9: The transverse radii R_{out} (left) and R_{side} (right) as a function of azimuthal angle with respect to the 2nd-order event plane Ψ_2 .

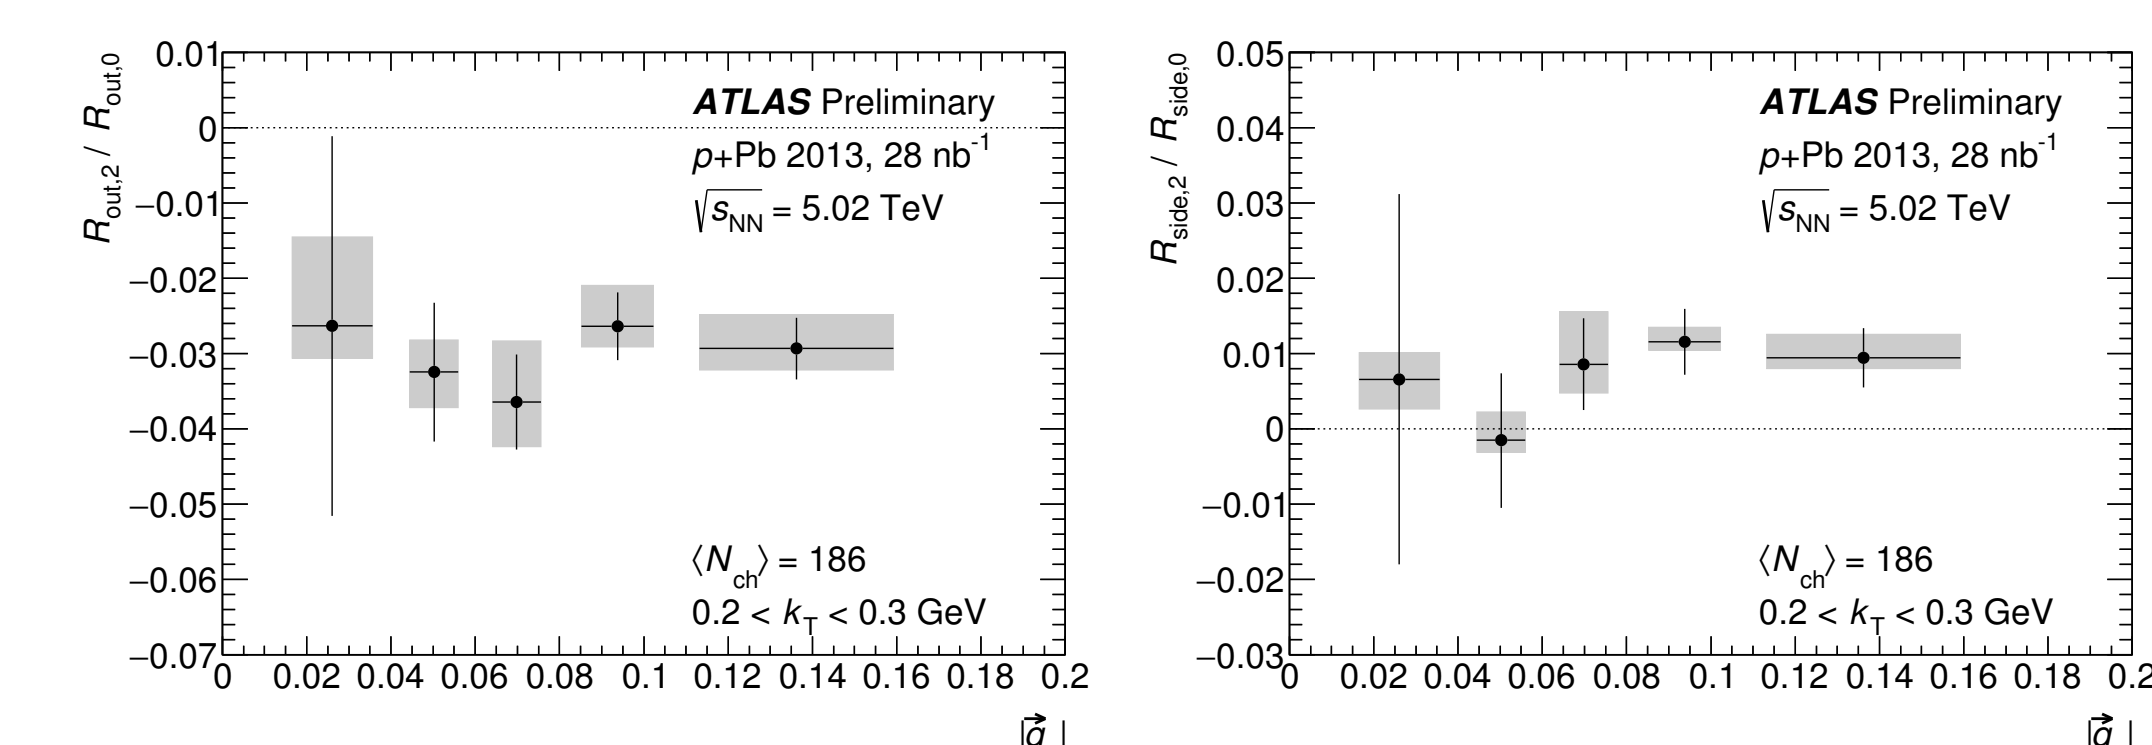

Figure 10: The normalized 2nd-order cosine Fourier components of the transverse radii R_{out} (left) and R_{side} (right) as a function of flow vector magnitude $|\vec{q}_2|$.

Highlighted observations

- Radii in central events show a decrease with rising k_T , which is qualitatively consistent with collective expansion. This trend is diminished in peripheral events.
- Within uncertainties, each HBT radius depends only on the local multiplicity dN_{ch}/dy^* .
- Evidence for a non-zero (positive) R_{01} is observed on the proton-going side of central events.
- The transverse shape of the freeze-out surface is consistent with short-lived hydrodynamic expansion in central events.
