

Anisotropic flow relative to the spectator plane in Pb+Pb collisions

Viktor Klochkov
(GSI / Frankfurt University)

Ilya Selyuzhenkov
(GSI / MEPhI)

for the NA61/SHINE Collaboration

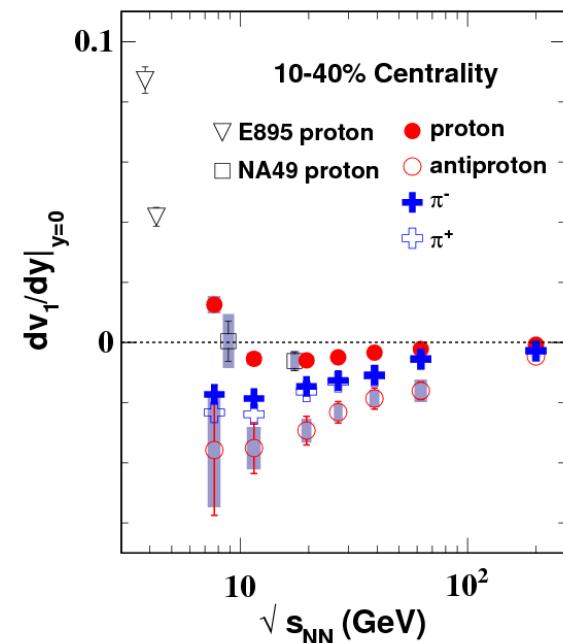

16 May, 2018

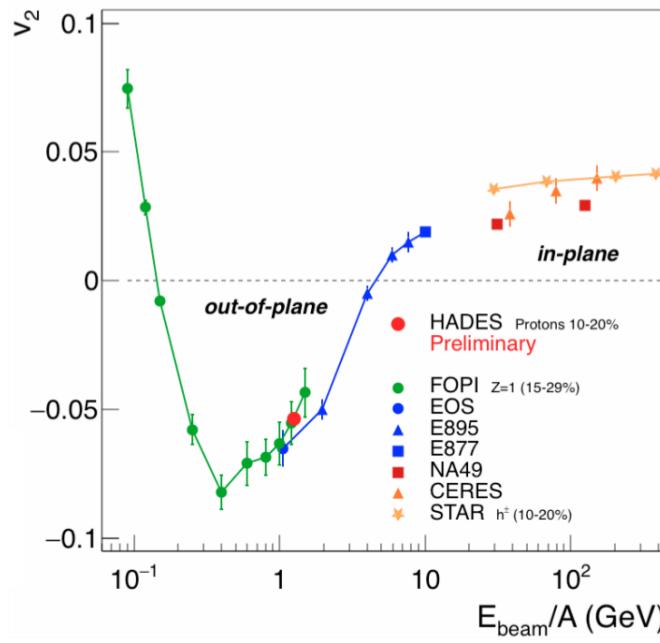

Collective flow at SPS / RHIC energies

Directed flow (slope)

STAR Collaboration
PRL 112 (2014) 162301

Elliptic flow

HADES Collaboration
JPCS 742 (2016) 012008

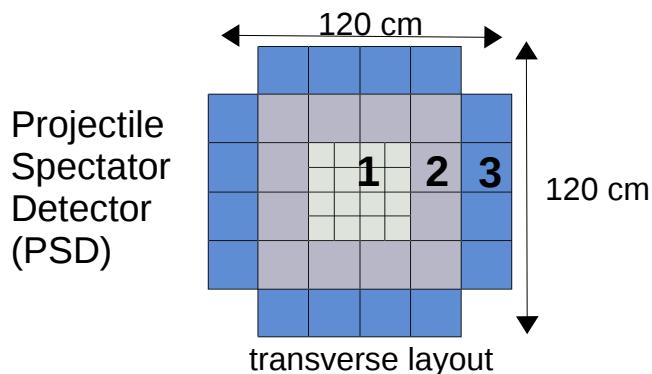

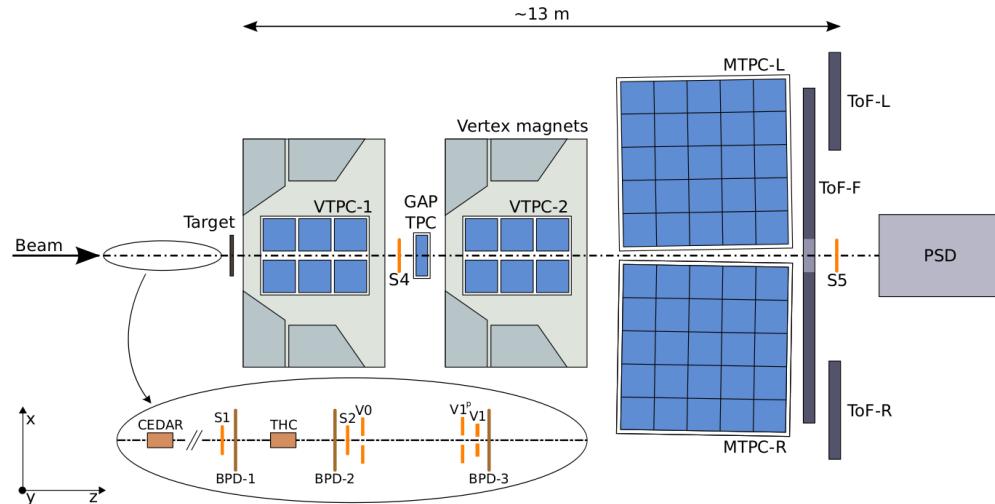

NA61/SHINE Pb-ion beam energy scan ($p_{LAB} = 13-150A$ GeV/c):

- Extend existing NA49 data
- Complementary to STAR@RHIC
- Bridge to FAIR/NICA beam energies

Advantage of the NA61/SHINE fixed target setup:

- Tracking and particle identification over wide rapidity range
- Projectile spectators measurement with forward calorimeter

Pb beam energy scan with NA61/SHINE at CERN SPS

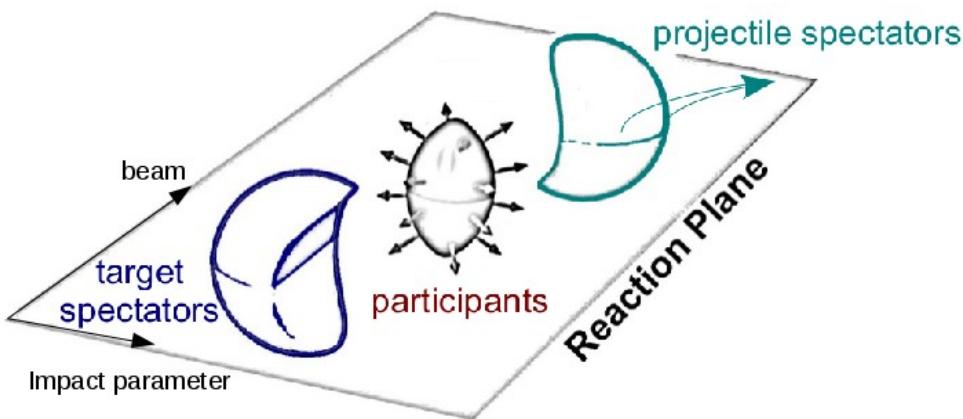

- Fixed target experiment
- Forward rapidity calorimeter (PSD)
- Large acceptance hadron spectrometer (TPC)
 - Full coverage of forward hemisphere
 - tracking + identification down to $p_T = 0 \text{ GeV}/c$
- Pb+Pb beam momentum scan:
 - 13A, **30A GeV/c** recorded in 2016 (pilot run at 150A GeV/c)
 - 150A GeV/c coming later this year 2018

Collision geometry and the anisotropic transverse flow

Asymmetry in coordinate space converts due to interaction into momentum asymmetry with respect to the symmetry plane:

$$\rho(\varphi) = \frac{1}{2\pi} [1 + 2 \sum_{n=1}^{\infty} v_n \cos(n(\varphi - \Psi_s))]$$

$$v_n = \langle \cos(n[\varphi - \Psi_s]) \rangle$$

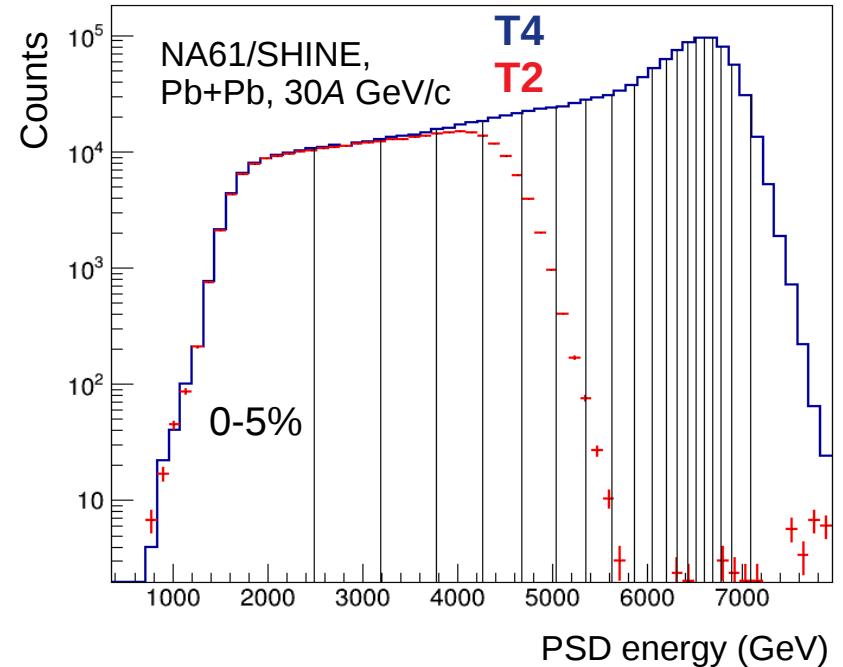

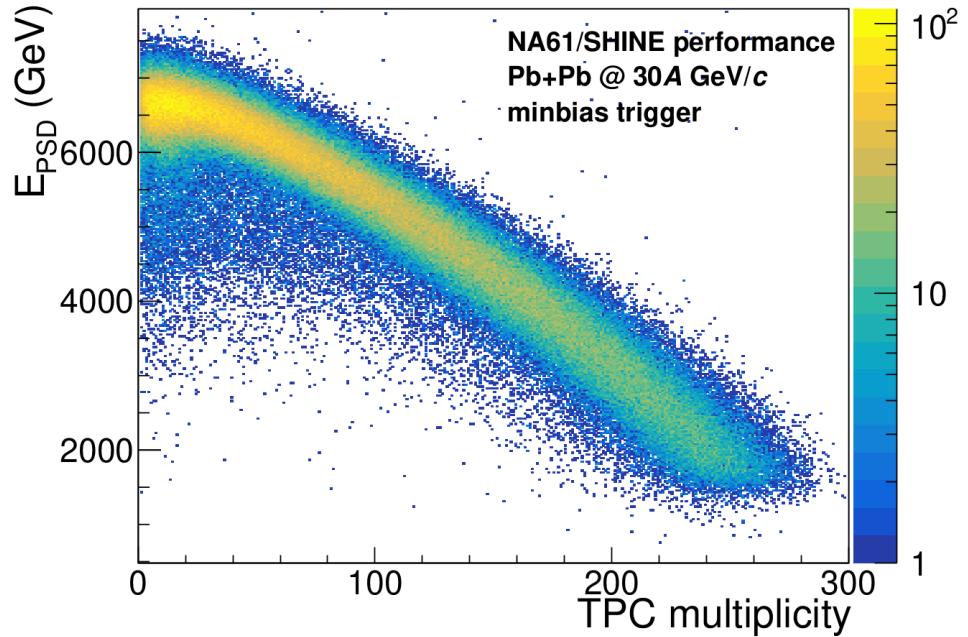

Ψ_s can be estimated from produced particles (Ψ_{pp}) or projectile (target) spectators Ψ_{proj} (Ψ_{targ})

Needed components to calculate v_n :

- momentum (φ, Y, p_T)
- centrality estimation
- particle identification
- symmetry plane (Ψ_s) estimation

Event selection

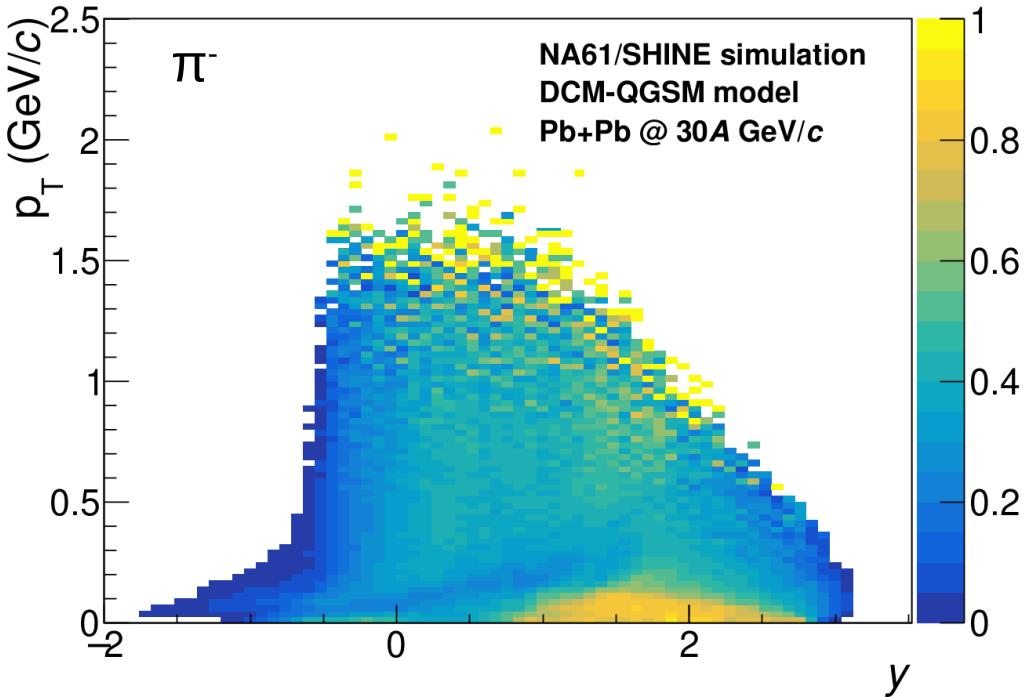

Event has fitted vertex
Good beam position
No overlap events / beam particles

$-593 < Z_{\text{vtx}}$ (cm) < -591
 $-1.1 < X_{\text{vtx}}$ (cm) < 0.0
 $-0.8 < Y_{\text{vtx}}$ (cm) < 0.4

Minimum bias trigger (T4): 1.1 M events
Central trigger (T2): 0.6 M events

Track selection and efficiency maps

Example of efficiency map

Number of clusters:

$$N_{\text{clusters}}\{\text{VTPC1+VTPC2}\} > 15$$

$$N_{\text{clusters}}\{\text{Total}\} > 30$$

$$0.55 < N_{\text{cl}}\{\text{Total}\}/N_{\text{cl}}\{\text{Total, pot}\} < 1$$

Distance of closest approach to vertex

$$|b_x| < 2 \text{ cm}$$

$$|b_y| < 1 \text{ cm}$$

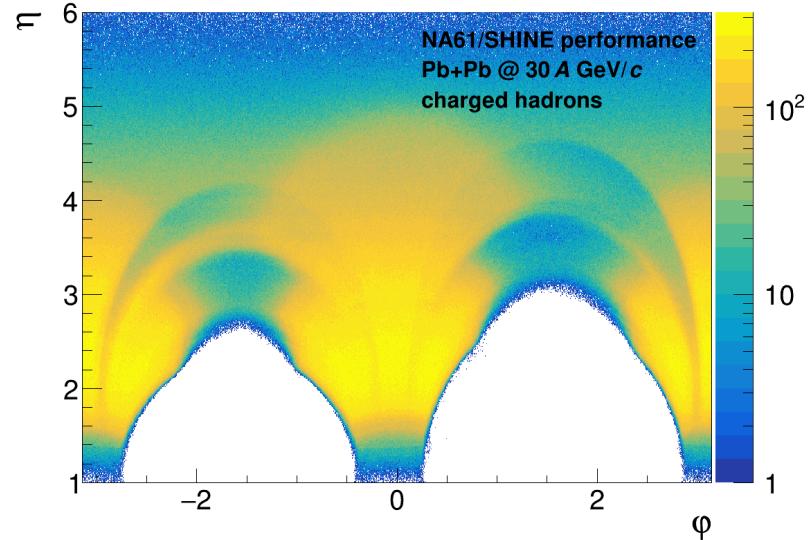

TPC energy loss (dE/dx)

charged pions & proton identification

Tracking efficiency

GEANT4 Monte-Carlo with DCM-QGSM

Corrections for detector azimuthal non-uniformity

QnVector Corrections Framework

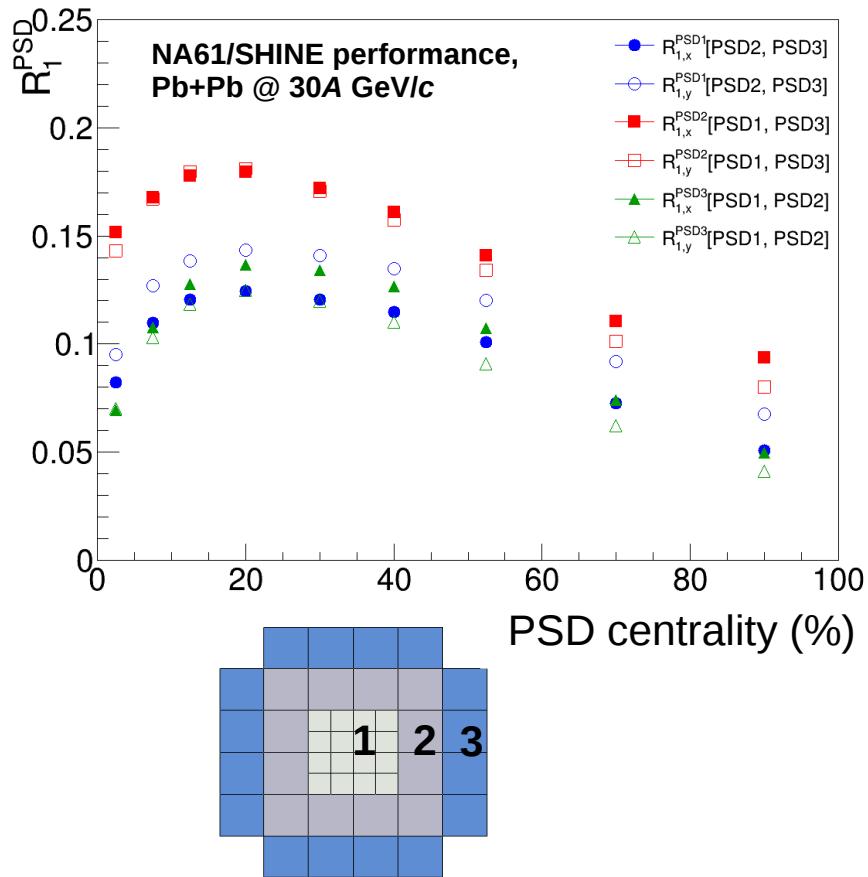

- Data driven corrections for azimuthal acceptance non-uniformity
I. Selyuzhenkov and S. Voloshin [PRC77 034904 (2008)]
- QnVector Corrections Framework (used by ALICE)
J. Onderwaater, V. Gonzalez, I. Selyuzhenkov
<https://github.com/jonderwaater/FlowVectorCorrections>
- Recentering, twist, and rescaling corrections applied time dependent (run-by-run) and as a function of centrality

Flow Analysis Framework

- Extended Q_n -vector corrections for p_T/y -differential
- Multi-dimensional correlations of u and Q -vectors
L. Kreis (GSI / Heidelberg) and I. Selyuzhenkov (GSI / MEPhI)

Scalar product method with 1st harmonic Q-vector

Scalar product correction factor

u and Q-vectors:

$$u_n = \begin{pmatrix} \cos n \varphi \\ \sin n \varphi \end{pmatrix} \quad Q_n = \sum_j u_n^j$$

Directed flow:

$$v_1 = \frac{\langle 2u_{1,i}Q_{1,i} \rangle}{R_{1,i}} \quad i, j, k = [x, y]$$

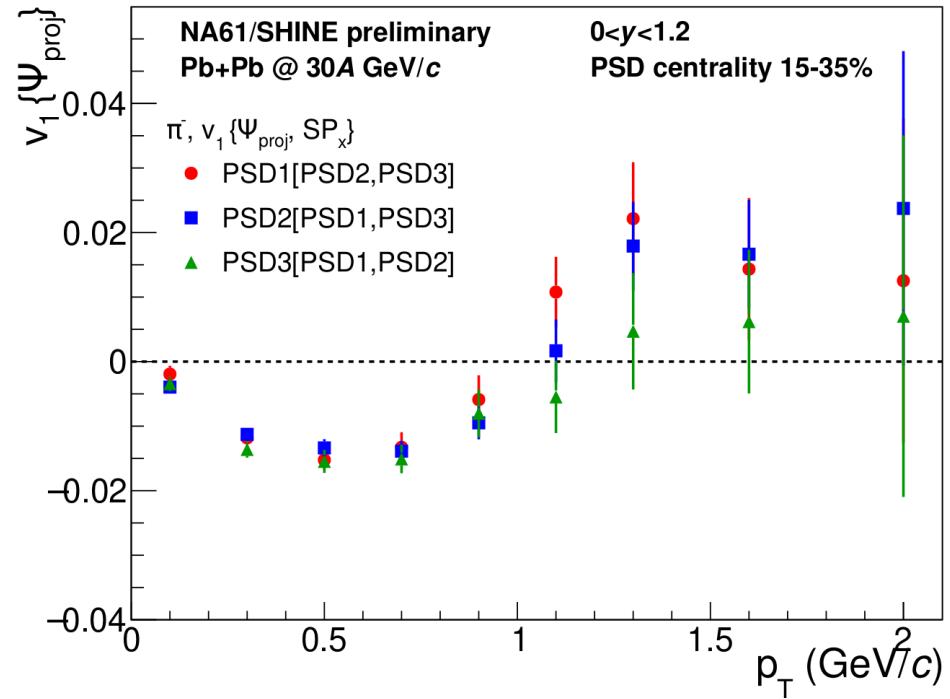

Elliptic flow:

$$v_2 = \frac{4 \langle u_{2,i}Q_{1,j}^A Q_{1,k}^B \rangle}{R_{1,j}^A R_{1,k}^B}$$

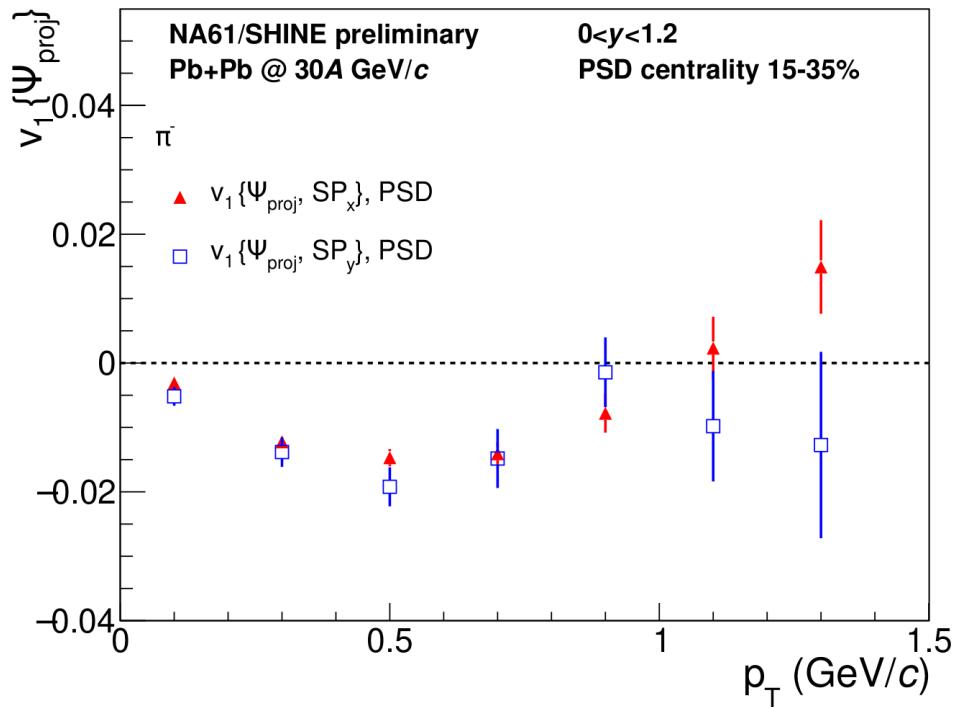

First harmonic resolution correction factor:

$$R_{1,i}^A[B, C] = \sqrt{2 \frac{\langle Q_{1,i}^A Q_{1,i}^B \rangle \langle Q_{1,i}^A Q_{1,i}^C \rangle}{\langle Q_{1,i}^B Q_{1,i}^C \rangle}}$$

“Systematics” for directed flow (v_1) components

Consistent results for PSD subevents

x/y components show consistent results, while results for y-component shows larger errors

For preliminary results: only x-component is used and PSD subevents are combined

Preliminary results & comparisons with NA49 and STAR

Results are presented for correlations between charged pions and protons* (in the TPC acceptance) and all hadrons at forward rapidity (in the PSD acceptance)

The results are corrected for detector non-uniformity.
No corrections for secondary interactions and weak decays are done yet.
Only statistical uncertainties are shown.

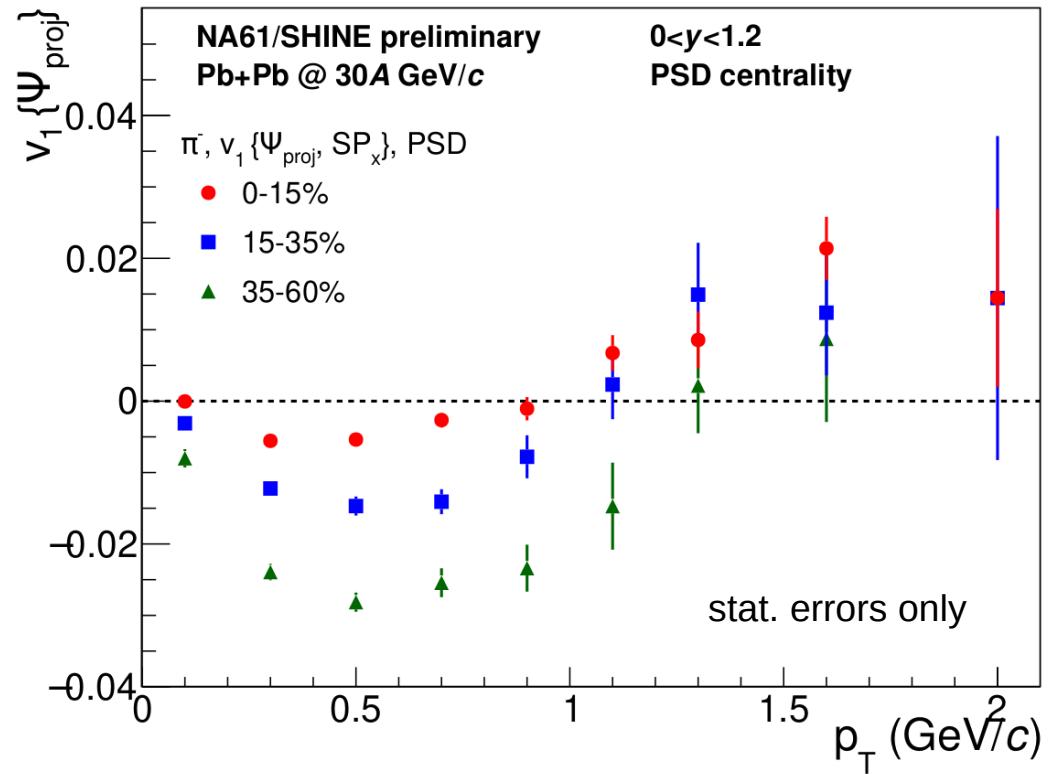

* hadrons produced by strong interaction processes and their electromagnetic decays

NA61/SHINE acceptance:

PSD: <https://edms.cern.ch/document/1867336/1>

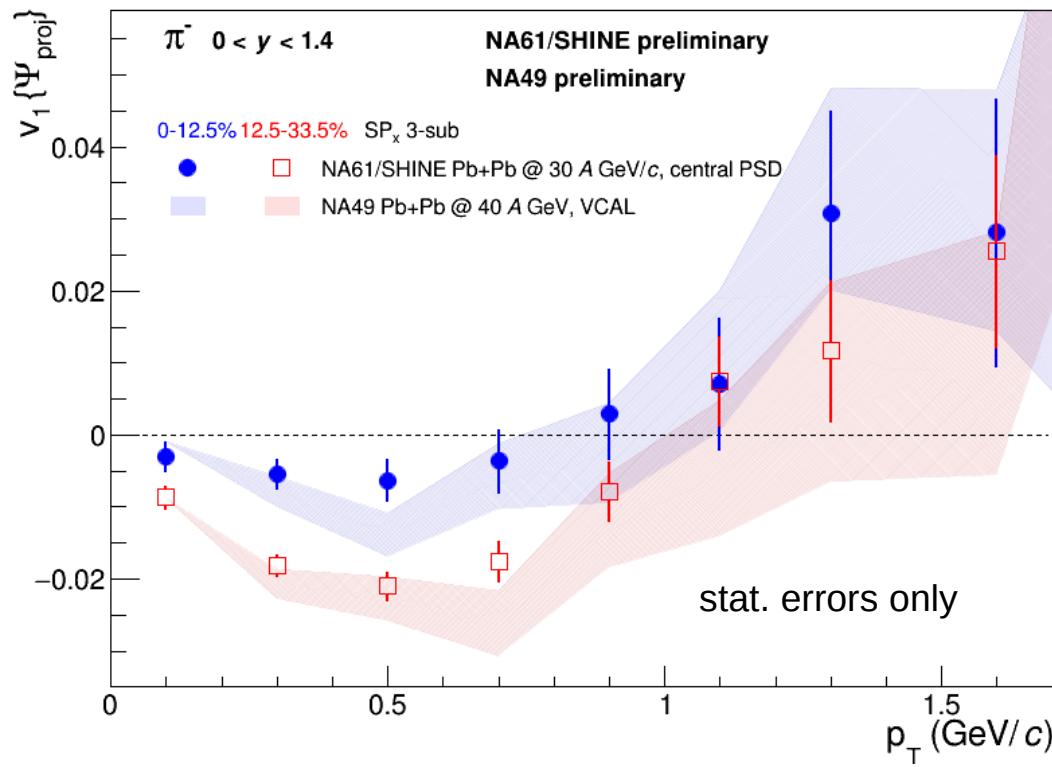

Charged pion v_1 vs transverse momentum

General features:

- Strong centrality dependence of v_1
- $v_1(p_T \sim 0 \text{ GeV}/c) = 0$
- v_1 changes sign at $p_T \sim 1 \text{ GeV}/c$

Comparison with the NA49 data

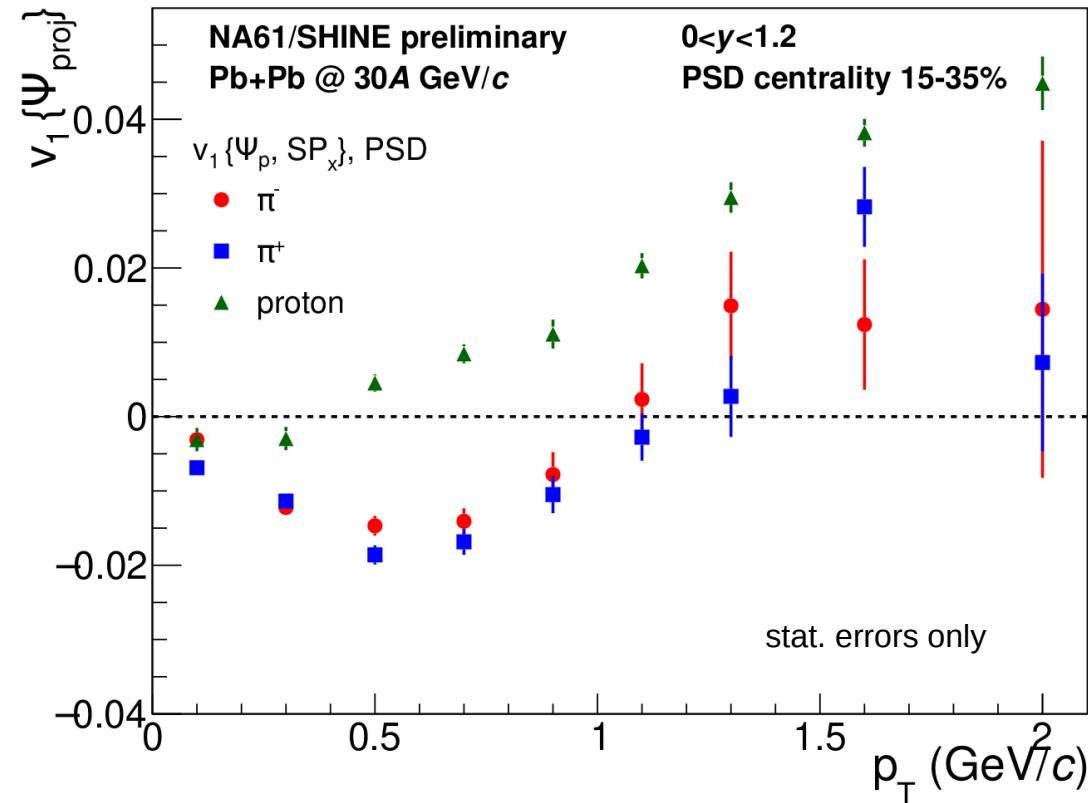

- Similar results to new NA49 analysis of pions relative to the spectator plane
- More details about new NA49 analysis and comparison with published NA49 data:

Poster #367:

O. Golosov, I. Selyuzhenkov,
V. Klochkov, and E. Kashirin

Particle type dependence of $v_1(p_T)$

- Significant mass dependence of v_1
 - Difference between π^+ and $\pi^- v_1$ is sensitive to the electromagnetic effects*
- Charged pions yield asymmetry from NA61/SHINE will be presented next week at WPCF2018 (M. Kielbowicz for NA61/SHINE)

* A. Rybicki, et al., Acta Phys.Polon. B46 (2015) no.3, 737
A. Rybicki, A. Szczerba, Phys.Rev. C87 (2013) no.5, 054909

Slope of v_1 at midrapidity vs. centrality

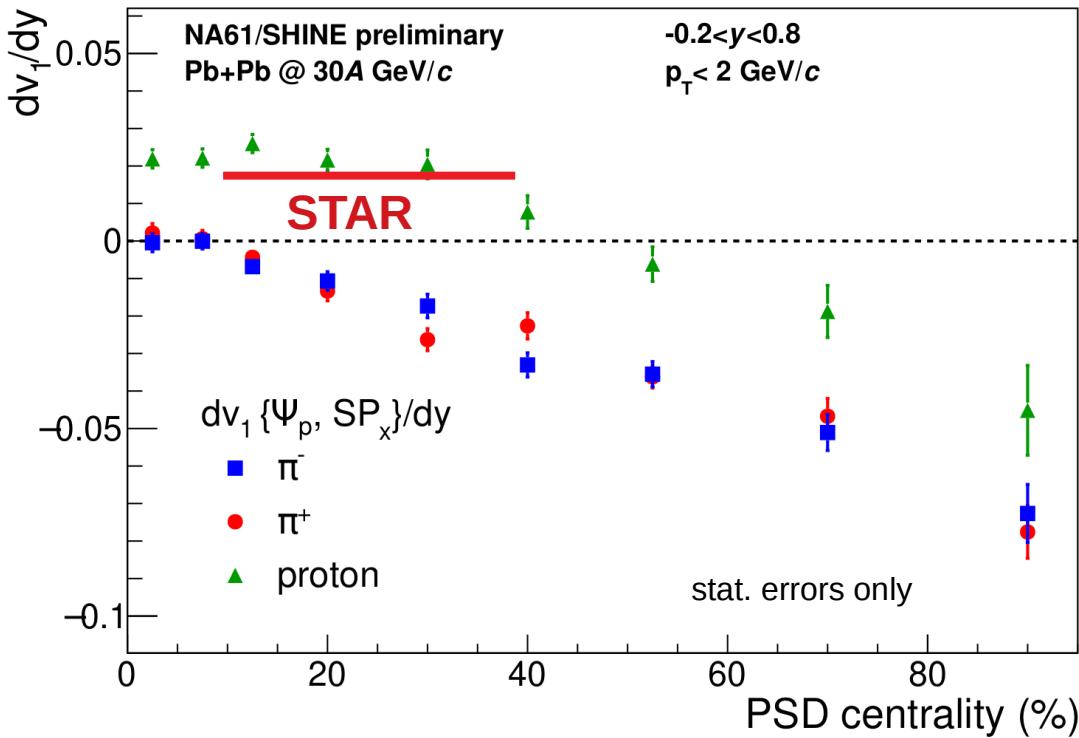

Slope extraction procedure:

- 1st order polynomial fit with 2 parameters (slope and offset):
 - offset for π^+/π^- consistent with 0 (all centrality)
 - Offset for protons is below 6×10^{-3} for centrality 0-60% and increasing up to 3×10^{-2} for centrality >60%.

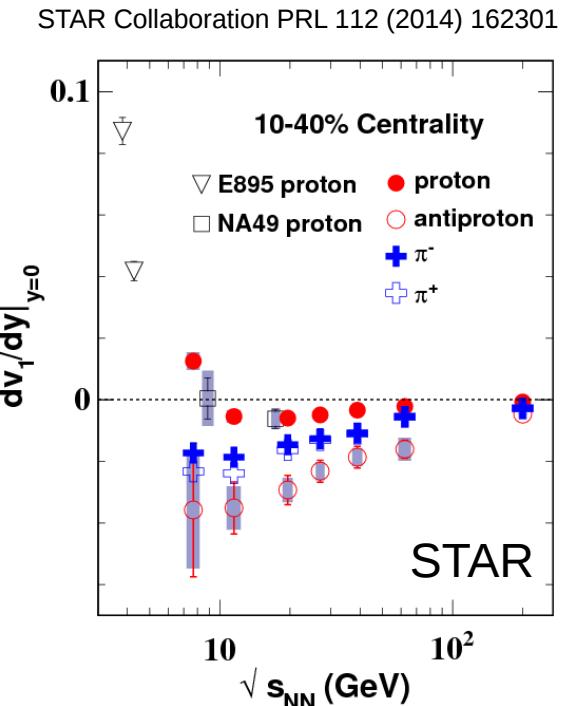

Observations:

- Slope of proton v_1 changes sign at about 50% centrality
- Slope of pions v_1 is always negative

Slope of v_1 at midrapidity: comparison with STAR

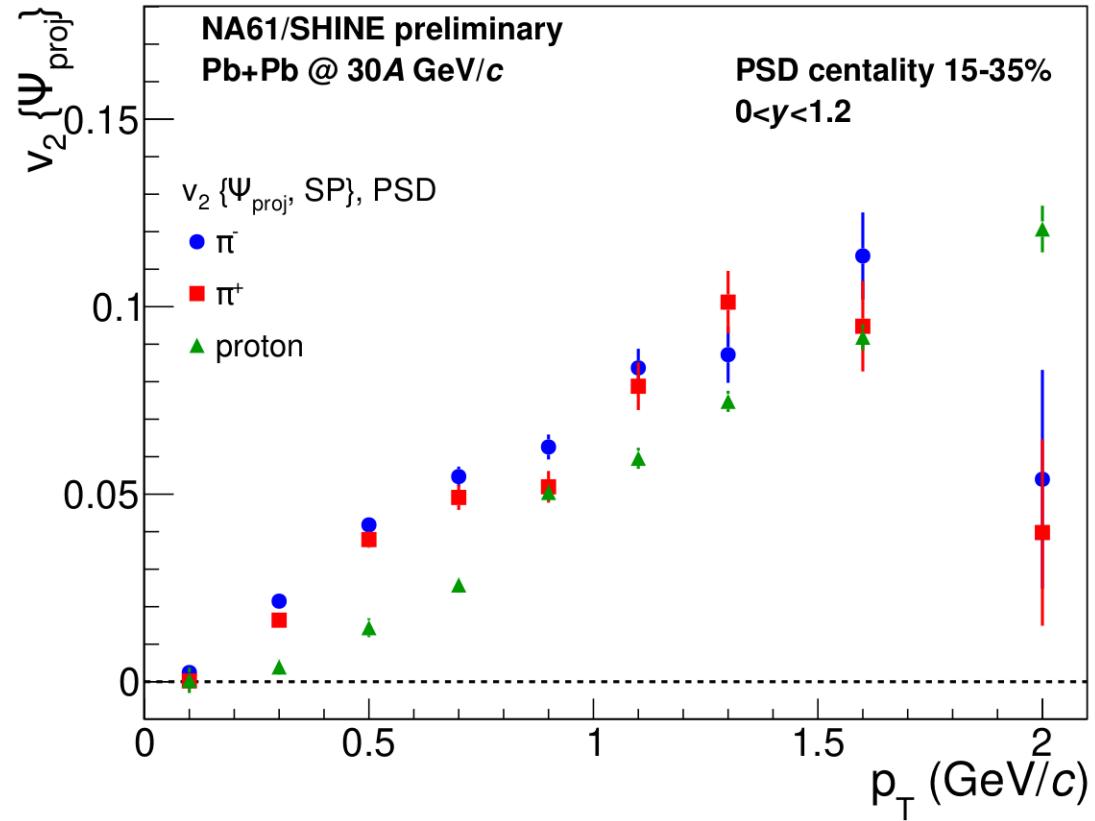

Slope extraction is sensitive to fit function and rapidity range

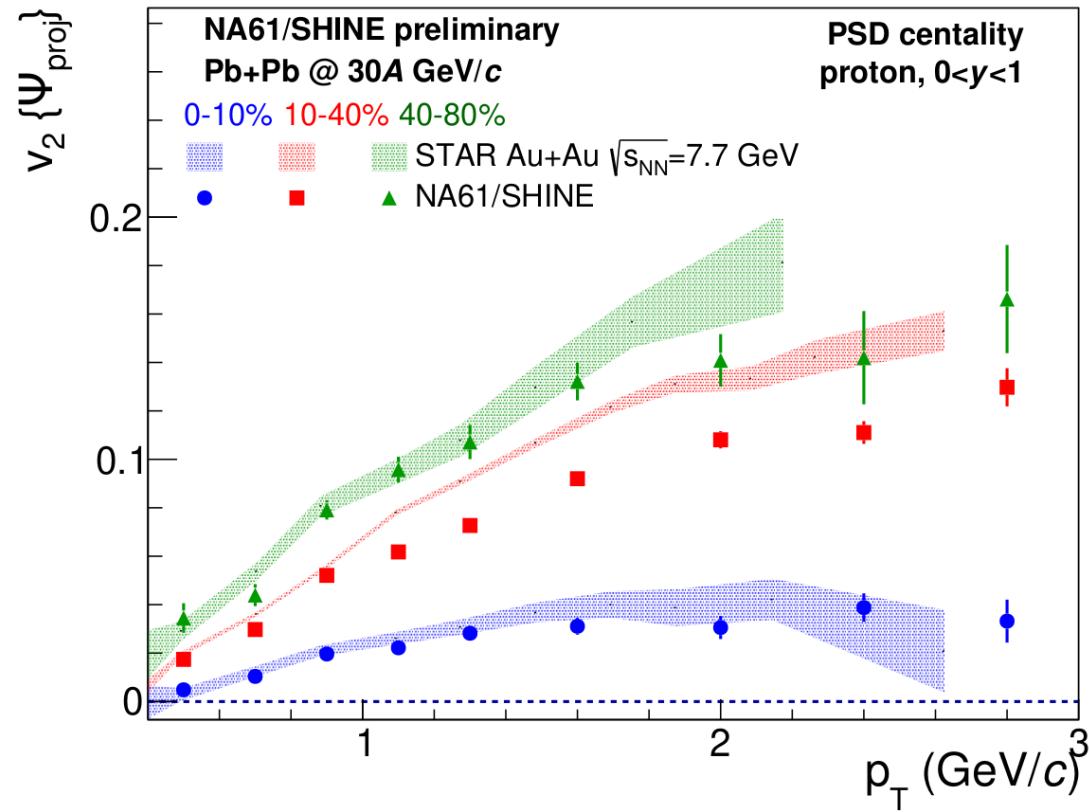

Preliminary results for centrality dependence presented by STAR Collaboration:
NPA 956 (2016) 260

Elliptic flow $v_2(p_T)$: particle type dependence

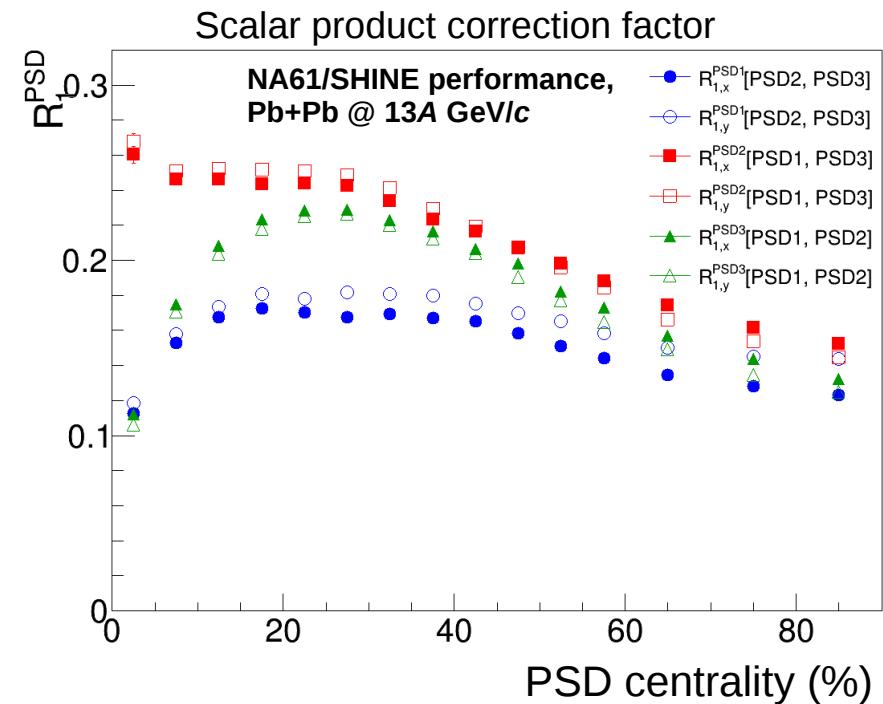

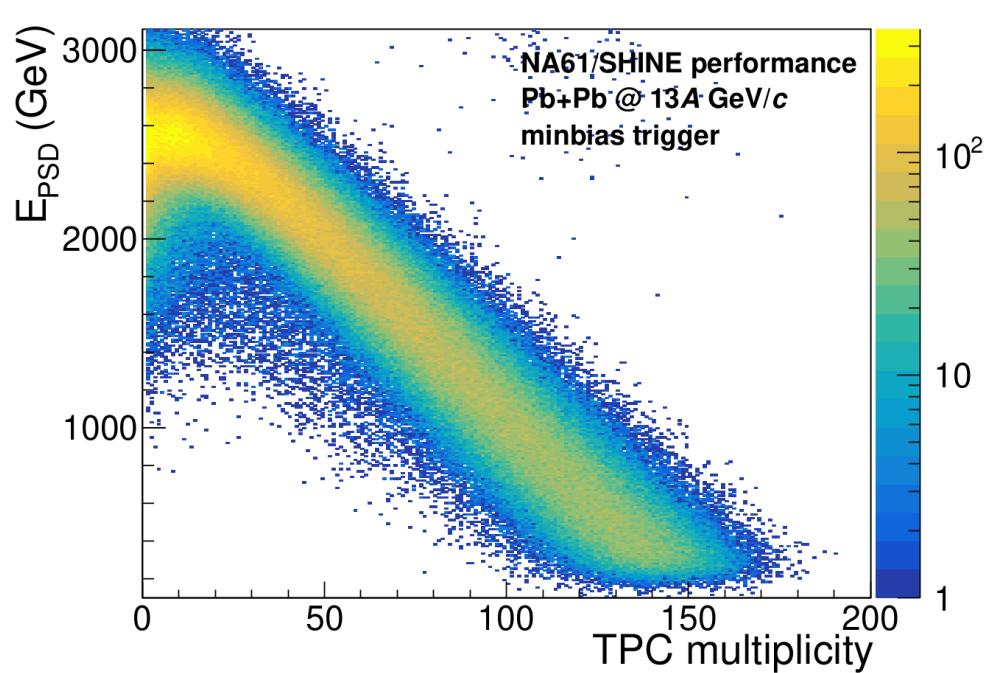

- Clear mass dependence
→ radial flow
- Difference between π^+ and $\pi^- v_2$ is small

Comparison of proton v_2 with STAR

- Similar results for central and peripheral
- Tension for mid-central collisions could be due to different centrality estimators:
 - ✓ Particle multiplicity at midrapidity (STAR)
 - ✓ Projectile spectators (NA61/SHINE)

Outlook for Pb ion beam energy scan: Pb+Pb @ 13A GeV/c

- Good performance of the Projectile Spectator Detector at lowest SPS energy
 - very close to the top energy of CBM @ FAIR
(CBM will have a similar forward calorimeter for centrality and spectator plane determination)

Summary

- Preliminary results for charged pions and protons directed and elliptic flow for Pb+Pb collisions at 30A GeV/c recorded in 2016 by the NA61/SHINE experiment are presented differentially vs. centrality, rapidity and transverse momentum
- Results are compared to the new analysis of the NA49 data using forward calorimeters and to the STAR@RHIC Beam Energy Scan data

Outlook

- Complete systematic analysis of the Pb ion beam energy scan data: 13A (2016) and 150A GeV/c (fall this year 2018)
- Study collective effects in smaller collision systems available from NA61/SHINE system size (Be+Be, Ar+Sc, Xe+La) and beam energy (13A–158A GeV/c) scan
