

## Strangeness and nuclei production in nuclear collisions

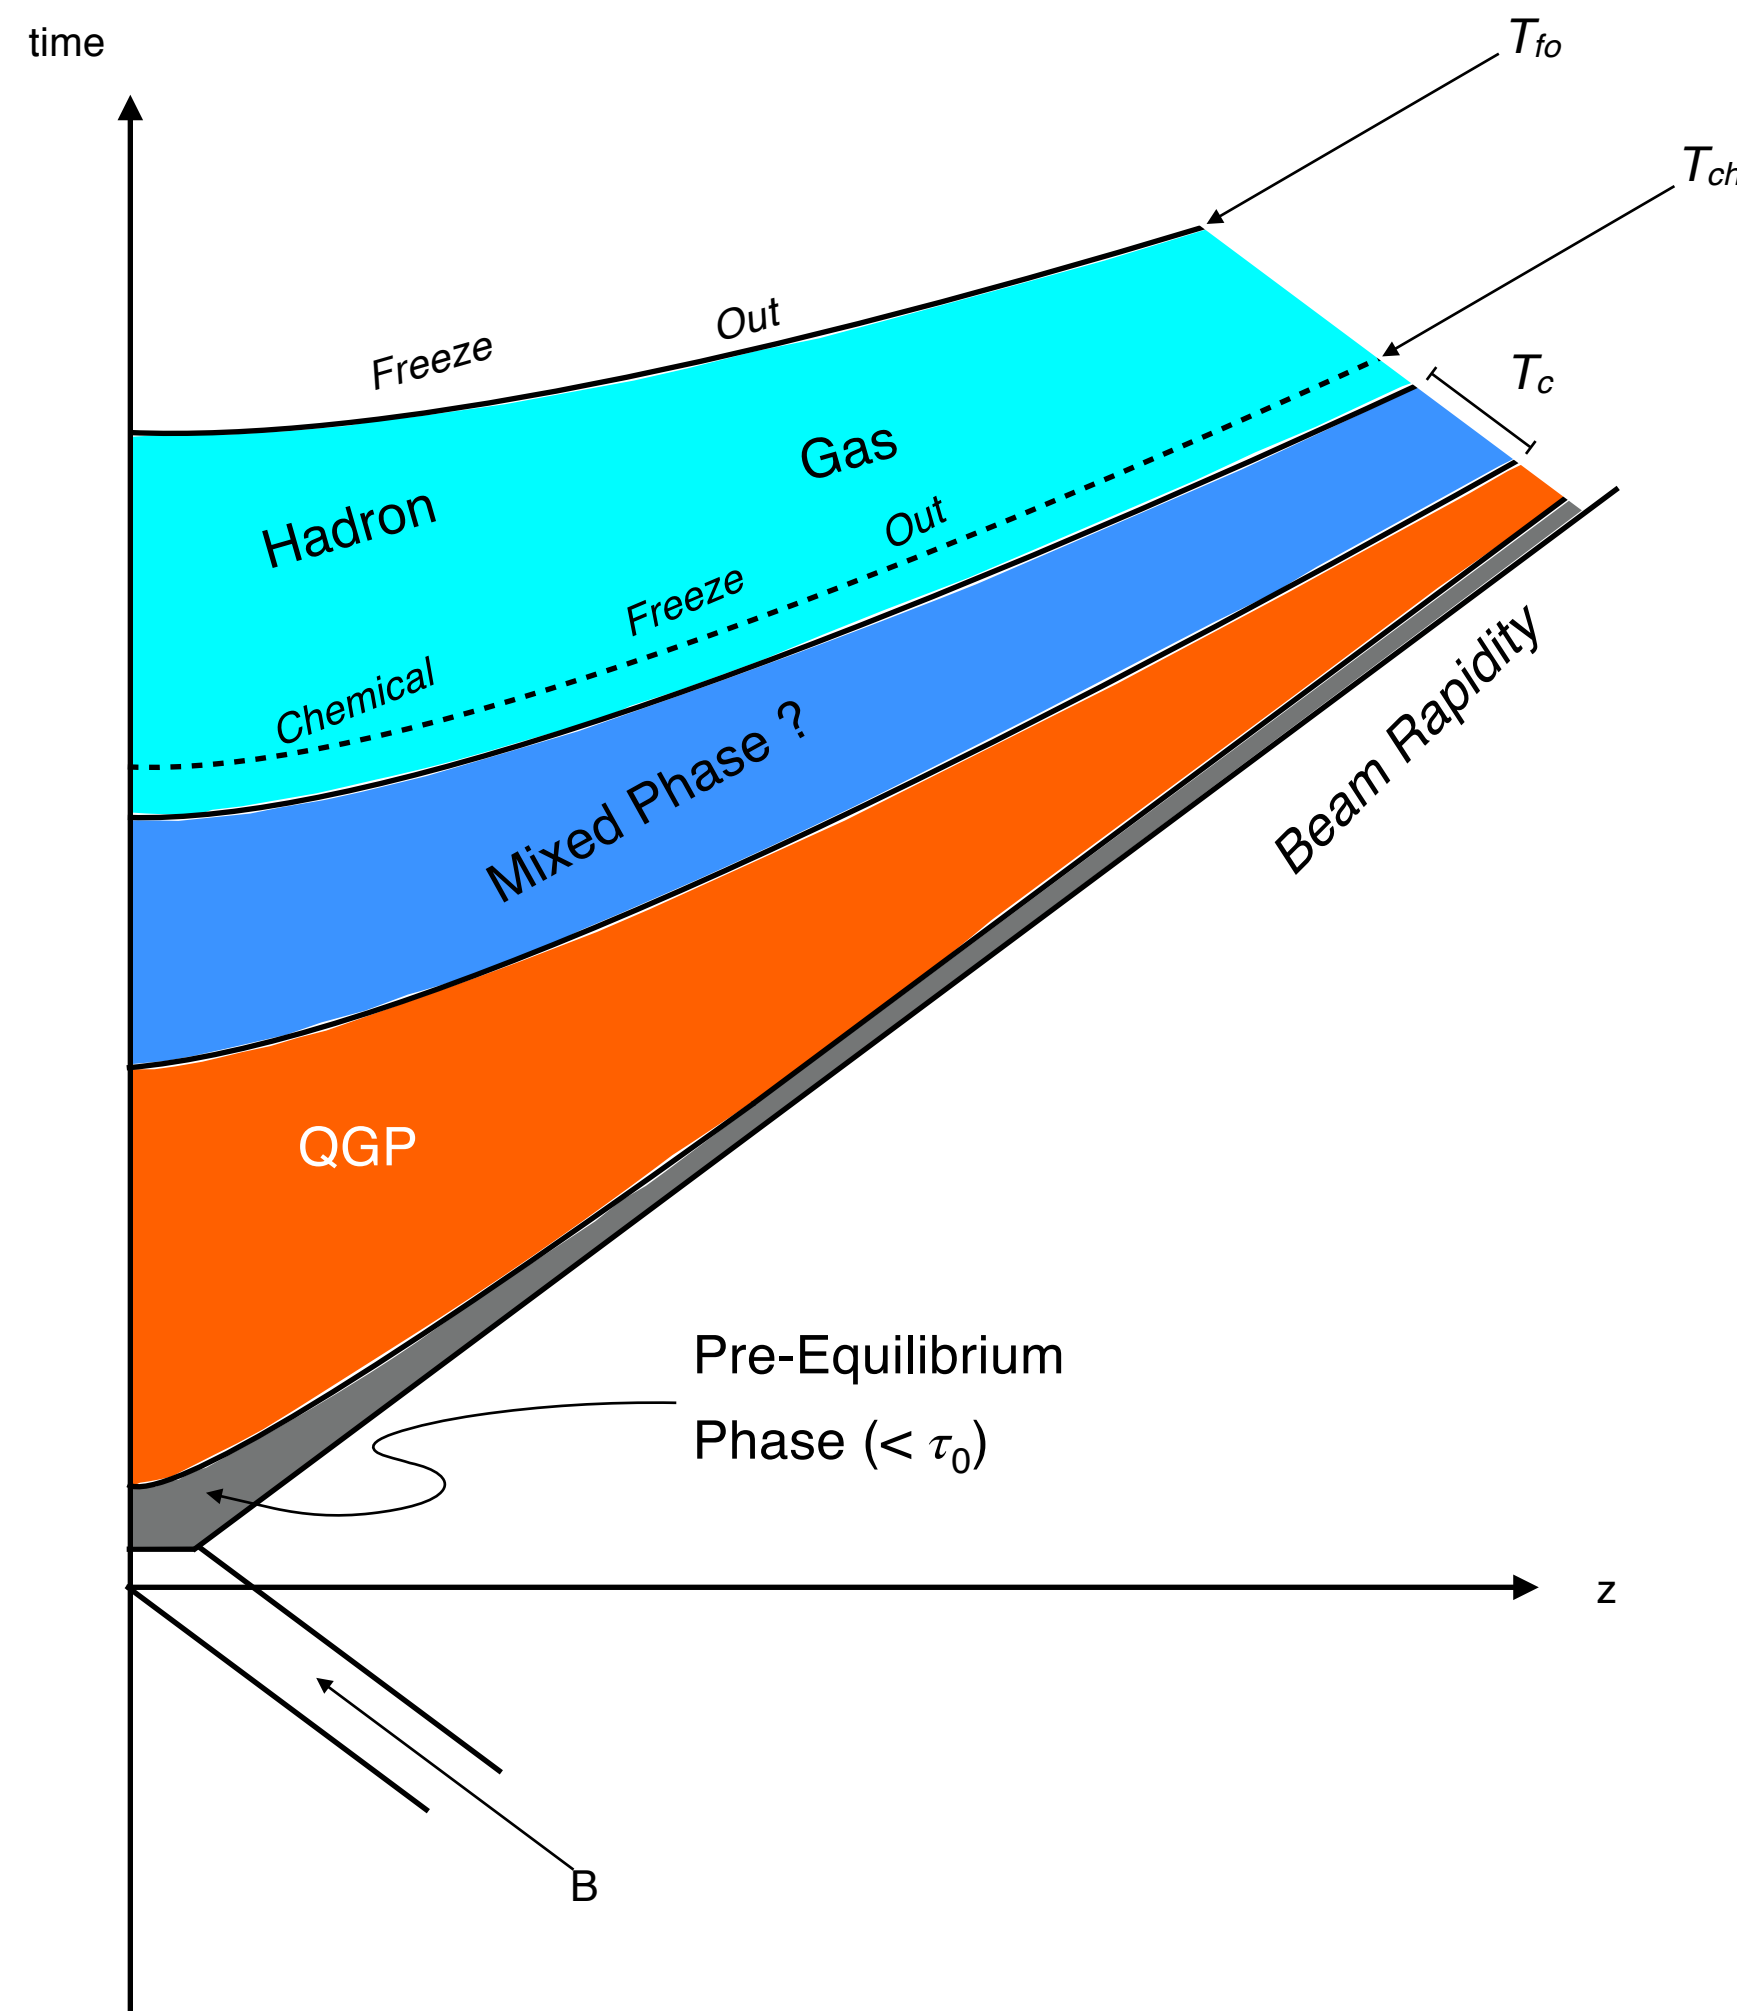

# Outline

- **Physics motivations: what can we learn?**
- **Strangeness as QGP signature: from SPS to LHC**
  - enhancement in small systems and model comparison;
  - elliptic flow at RHIC and at the LHC.
- **Light (anti-)nuclei production**
  - $p_T$  spectra and coalescence parameters from ALICE, STAR and HADES;
  - model comparison.
- **(Anti-)hypernuclei in heavy-ion collisions**
  - lifetime measurement from STAR and ALICE;
  - CPT symmetry test via mass difference measurement.
- **Conclusions**

# Motivation for strangeness physics

**1982 (Rafelski, Muller): Strangeness enhancement** relative to elementary collisions proposed as smoking gun for **QGP formation**

- Lower Q-value for  $s\bar{s}$  relative to  $HsH\bar{s}$  formation
- Faster equilibration in partonic medium

Statistical Hadronization Model describes well hadron formation for very different colliding systems and energies

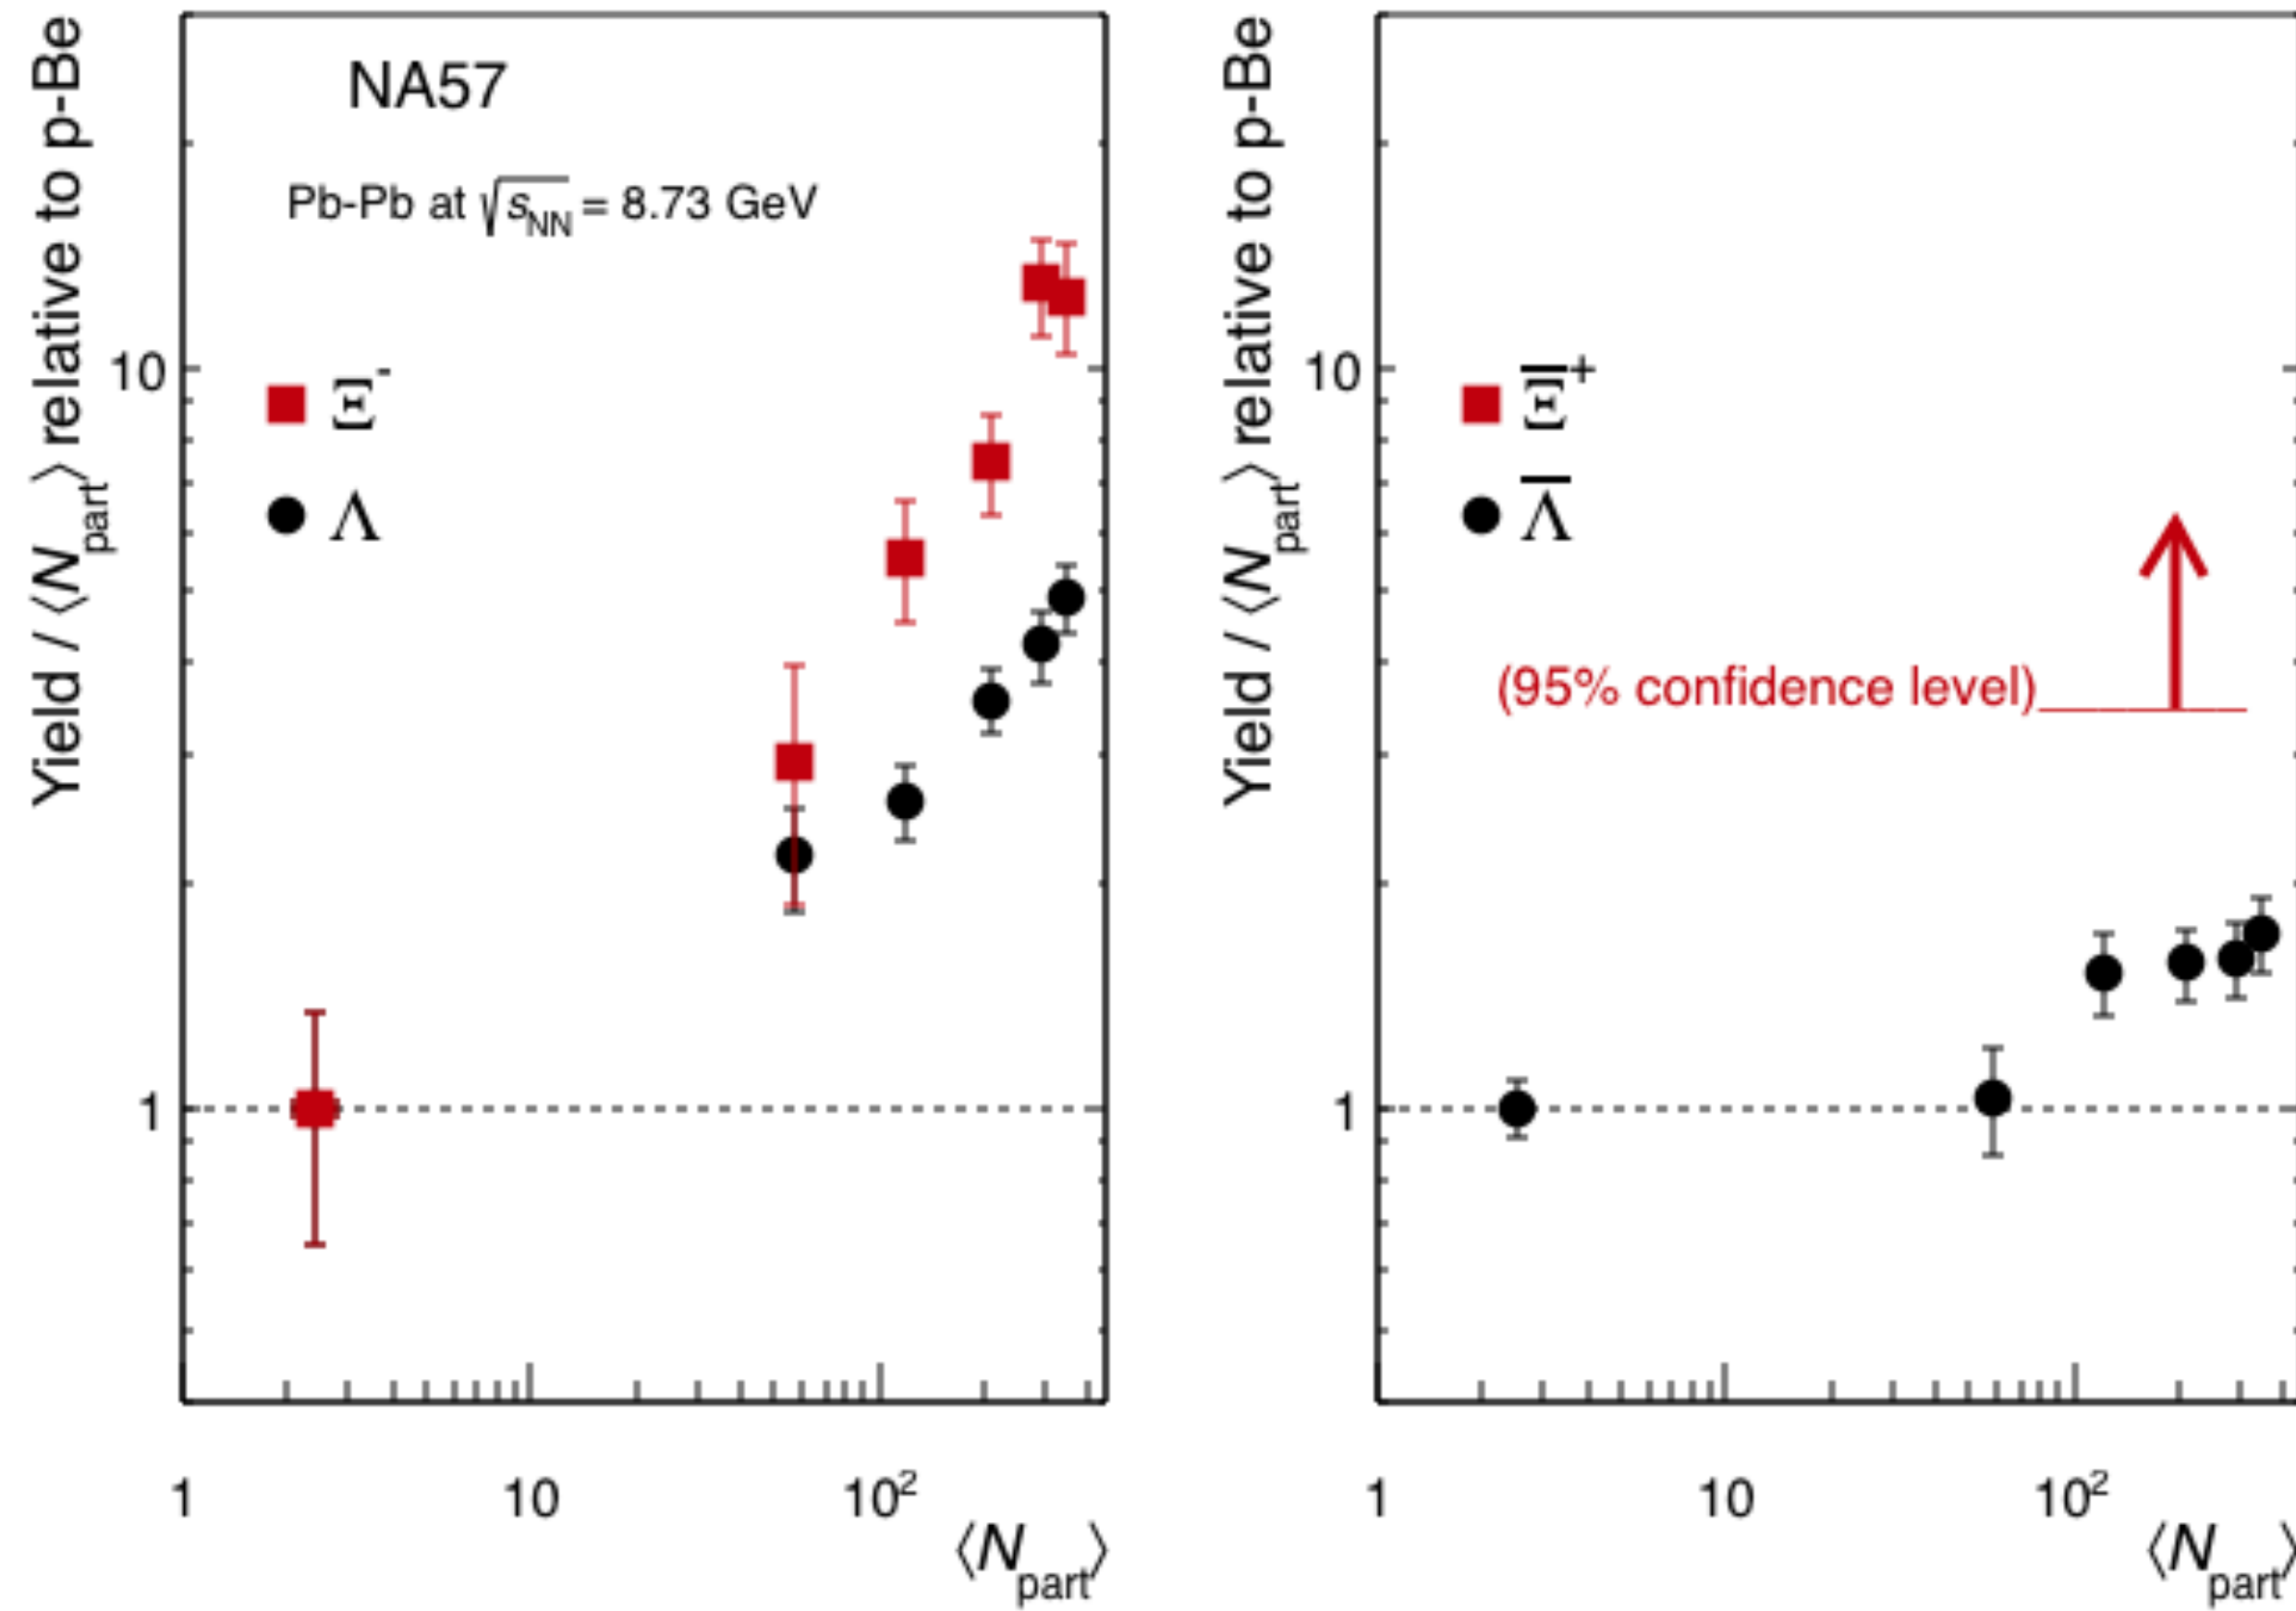

BUT

**What is the microscopical underlying mechanism which brings the system to enhance strangeness?**

**Can we anyway infer something about the QGP?**

# Strangeness enhancement: QGP signature at SPS

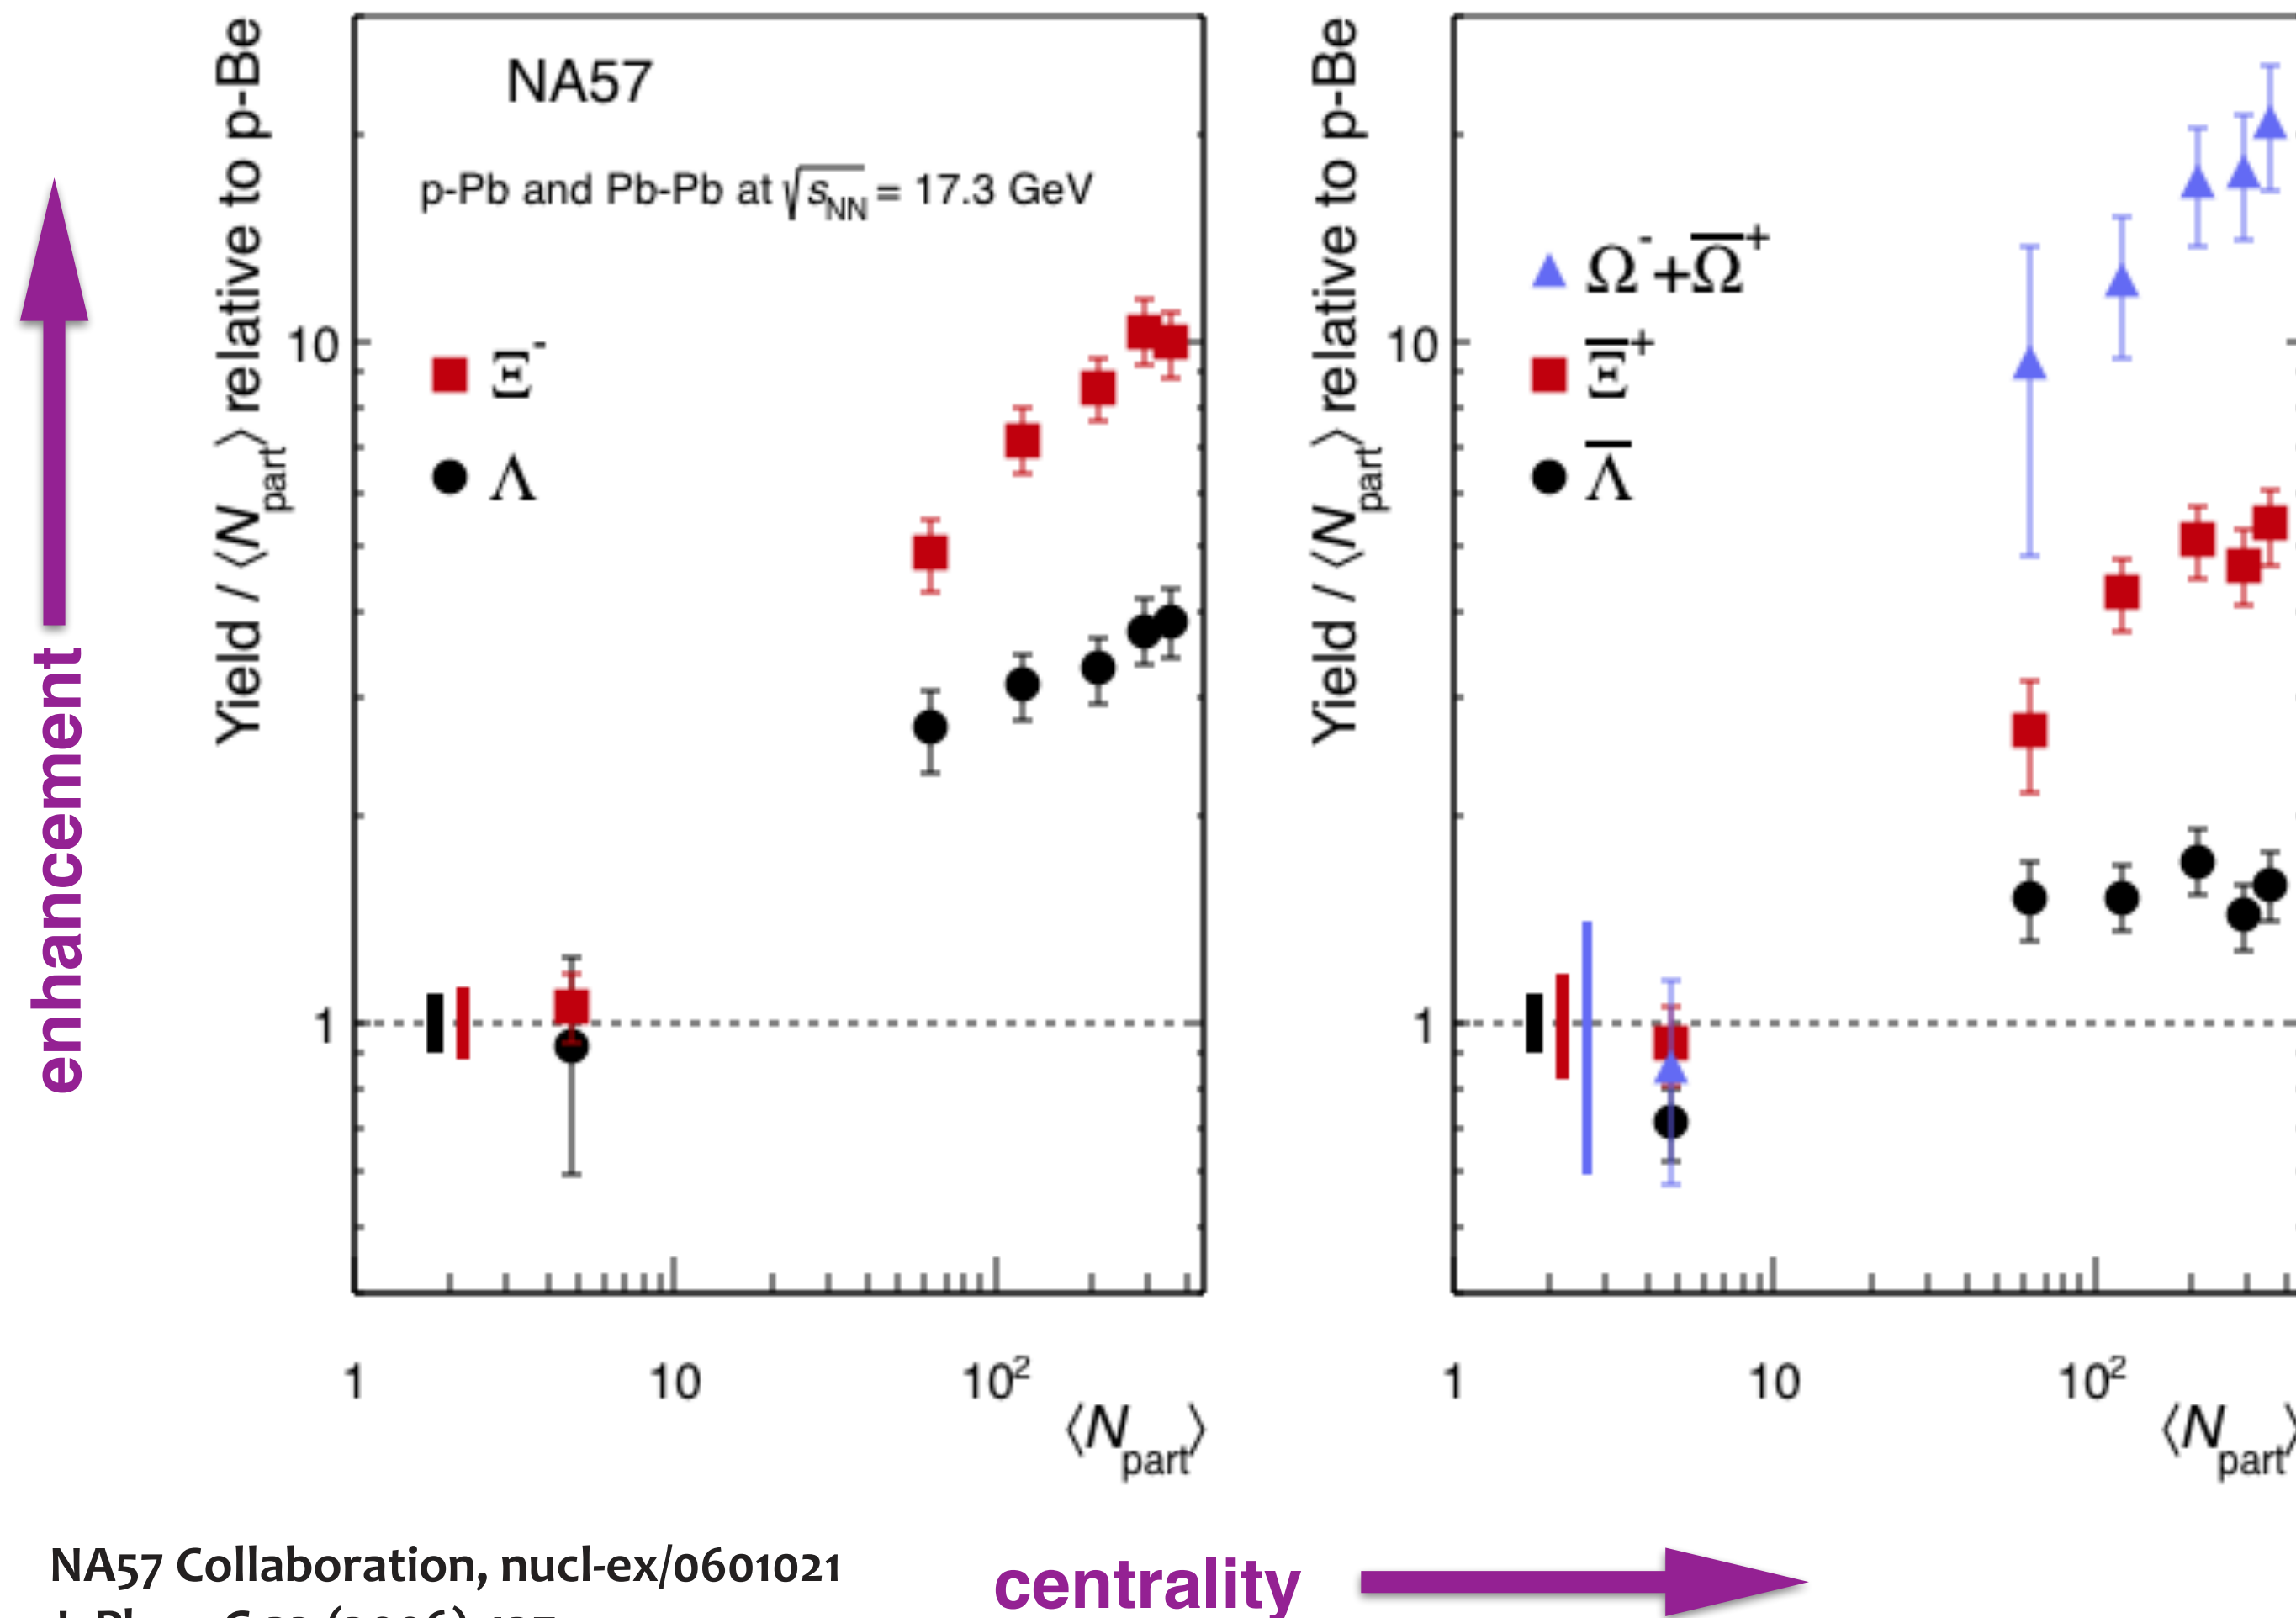

enhancement ↑

centrality →

- Pb-Pb at SPS -  $\sqrt{s_{NN}} = 8.73$  GeV
- Higher enhancement when
  - centrality increases
  - the numbers of strange valence quark is higher

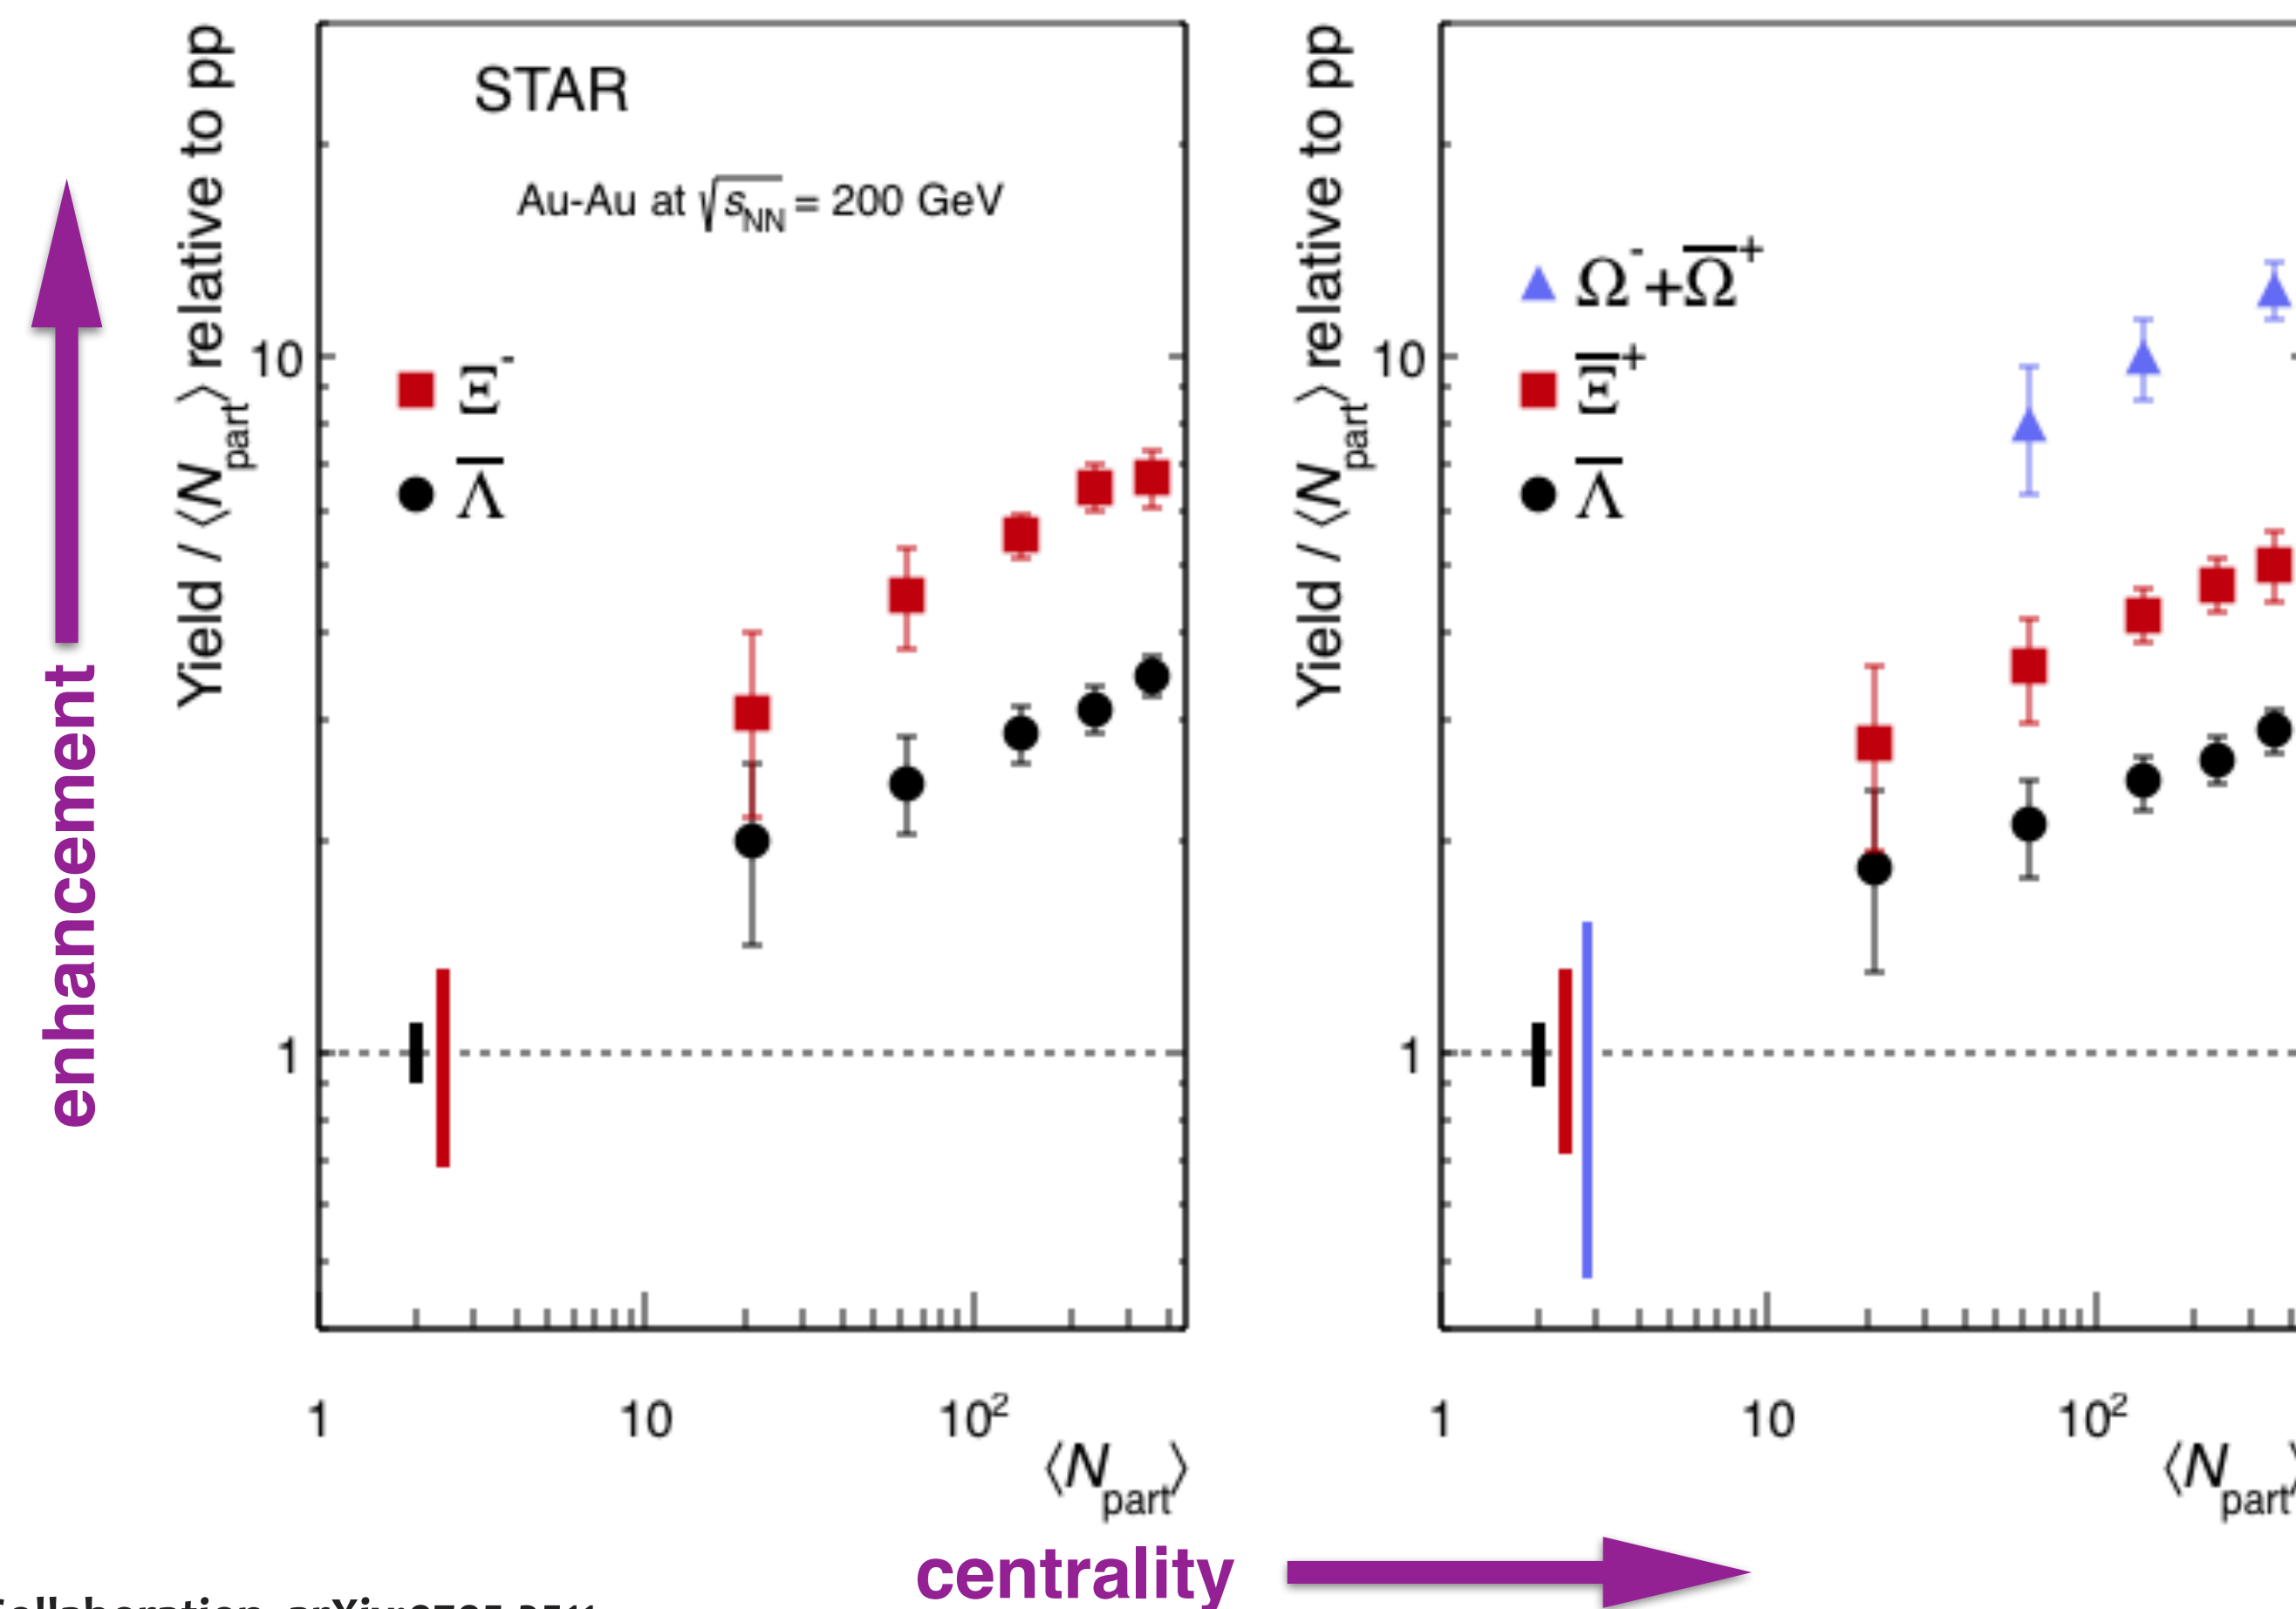

# Strangeness enhancement: QGP signature at SPS

NA57 Collaboration, nucl-ex/0601021  
J. Phys. G 32 (2006) 427

- Pb-Pb at SPS -  $\sqrt{s_{NN}} = 8.73$  GeV
- Pb-Pb at SPS -  $\sqrt{s_{NN}} = 17.3$  GeV
- Higher enhancement with increasing centrality and when baryons contain a higher numbers of strange valence quark **confirmed**

# Strangeness enhancement: QGP signature at RHIC

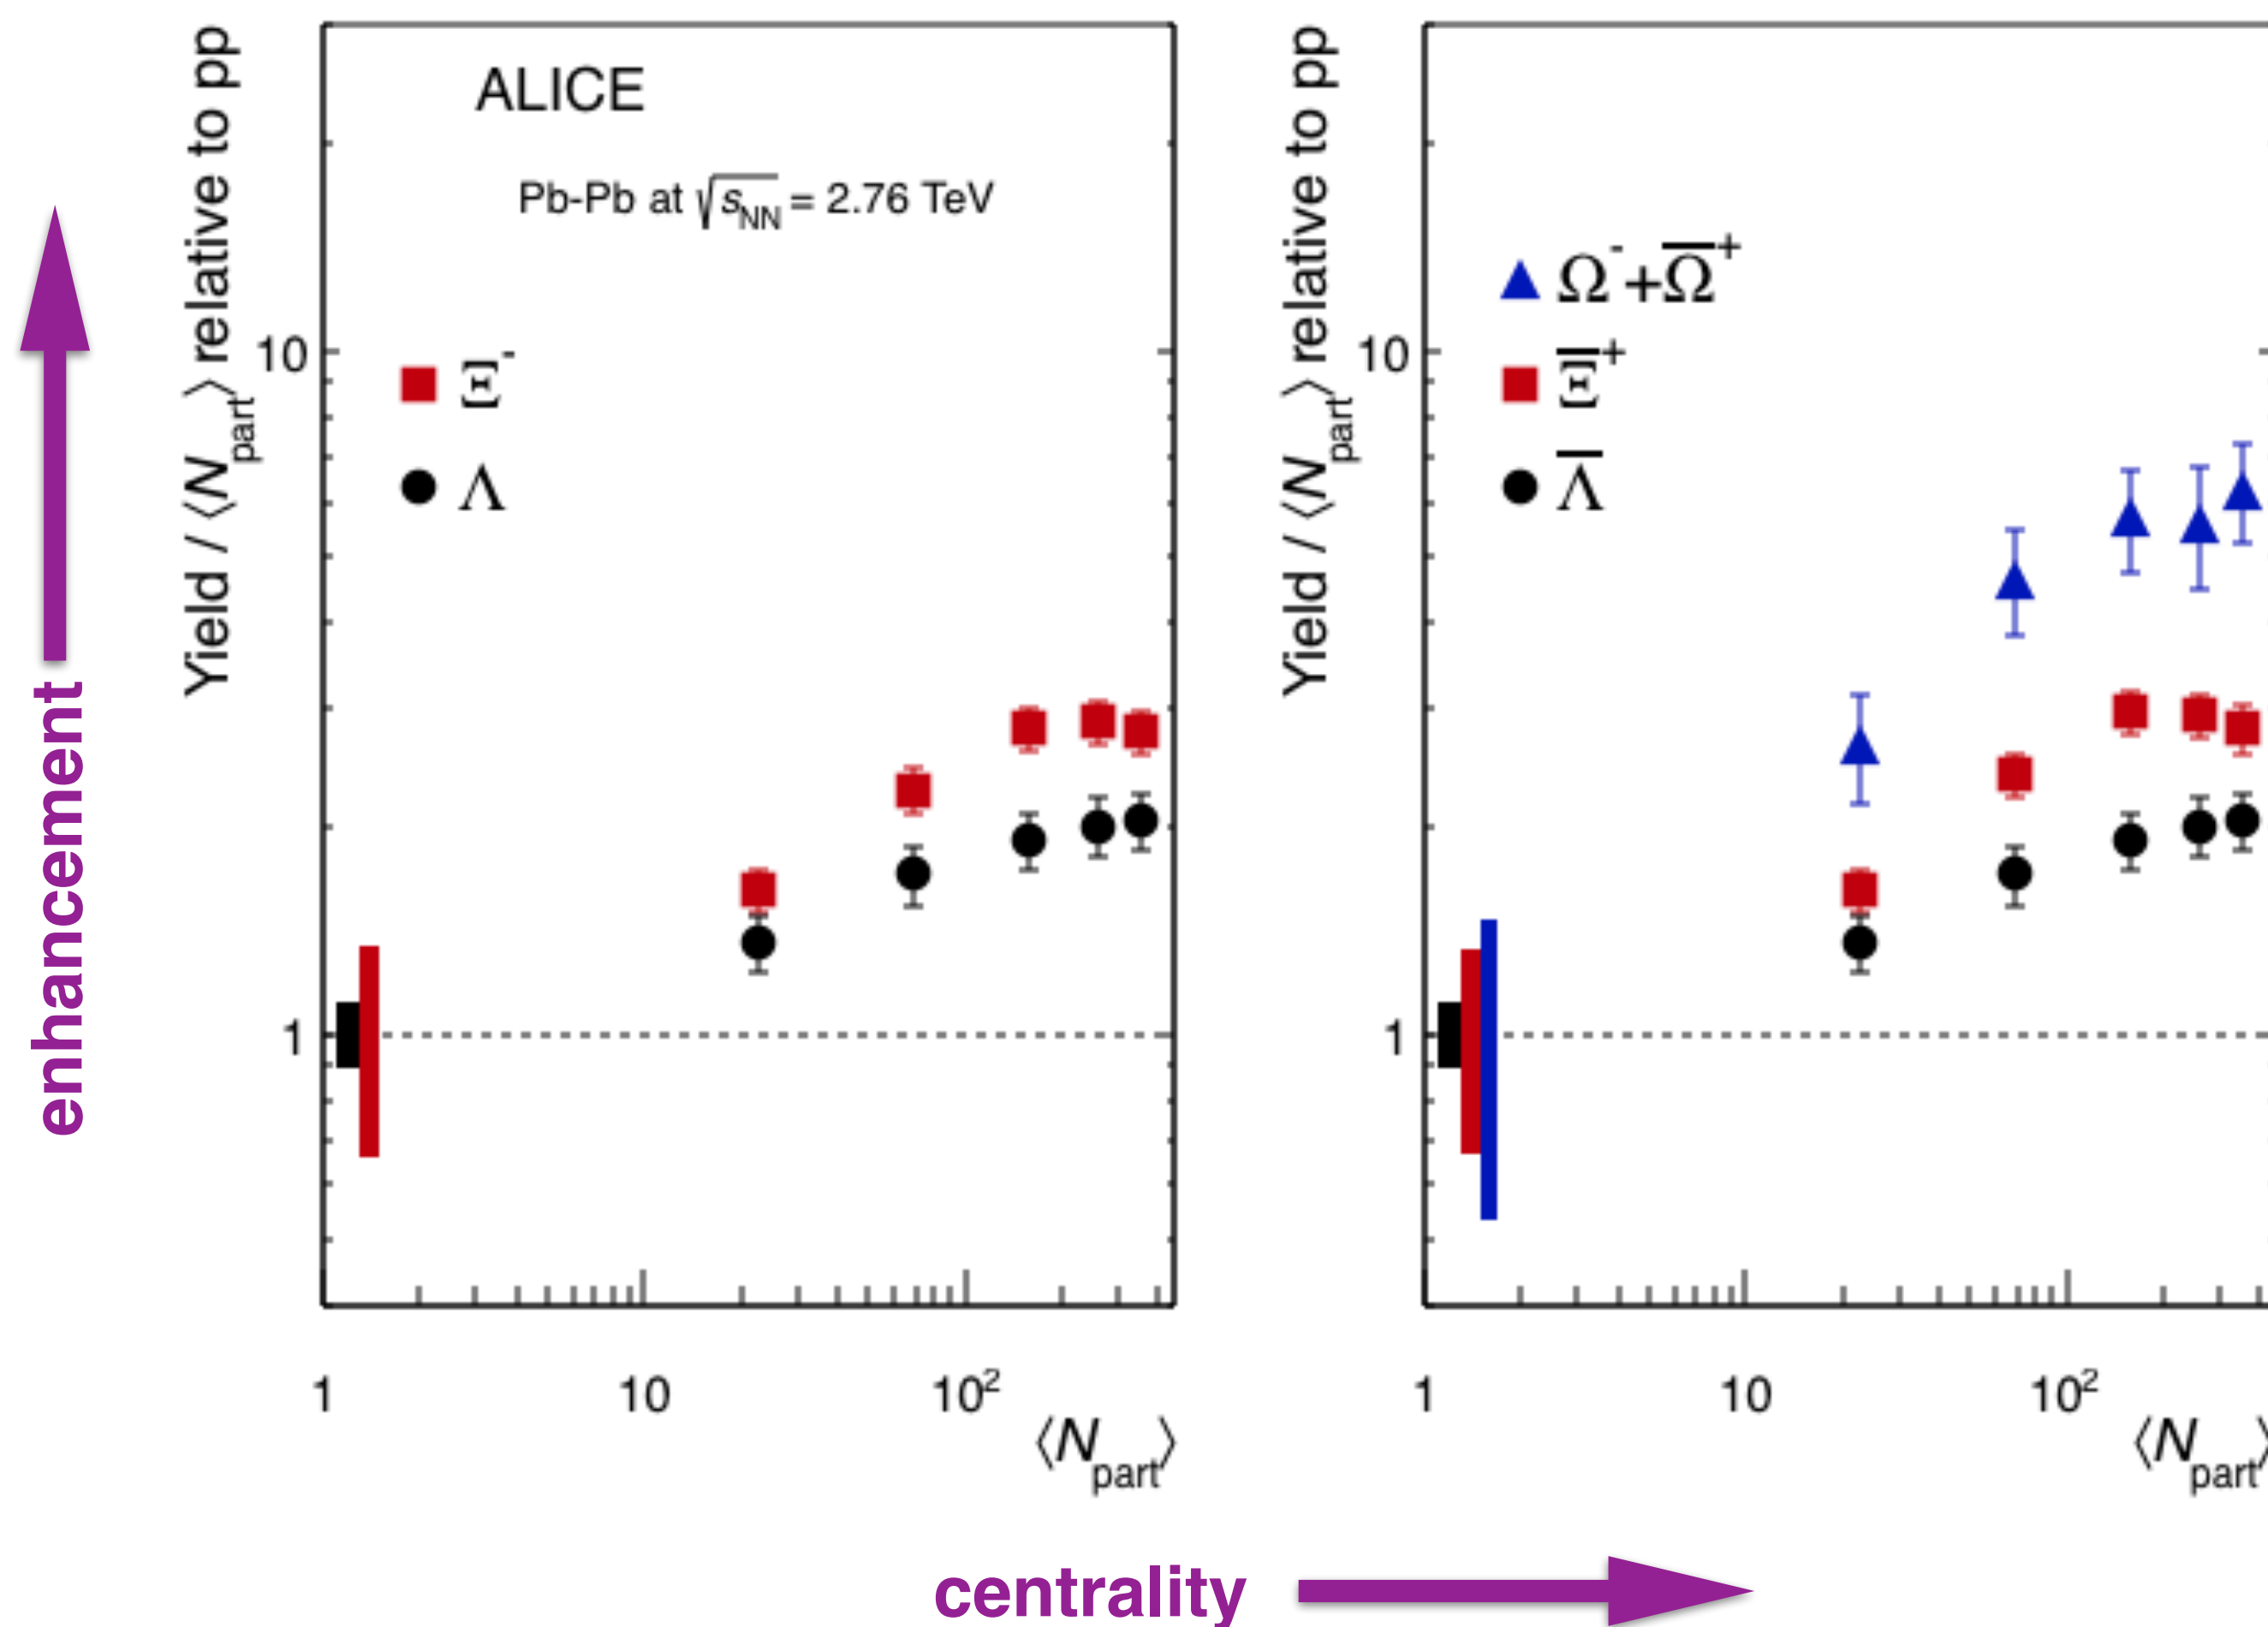

- Pb-Pb at SPS -  $\sqrt{s_{NN}} = 8.73$  GeV
- Pb-Pb at SPS -  $\sqrt{s_{NN}} = 17.3$  GeV
- Au-Au at RHIC -  $\sqrt{s_{NN}} = 200$  GeV

RHIC results confirm the picture:

- ➔ higher statistics (more precise results) and wider centrality range
- ➔ **BUT**: slightly lower enhancement (x15 for the  $\Omega$  w.r.t. a x20 factor measured at SPS)

STAR Collaboration, arXiv:0705.2511  
Phys. Rev. C 77 (2008) 044908

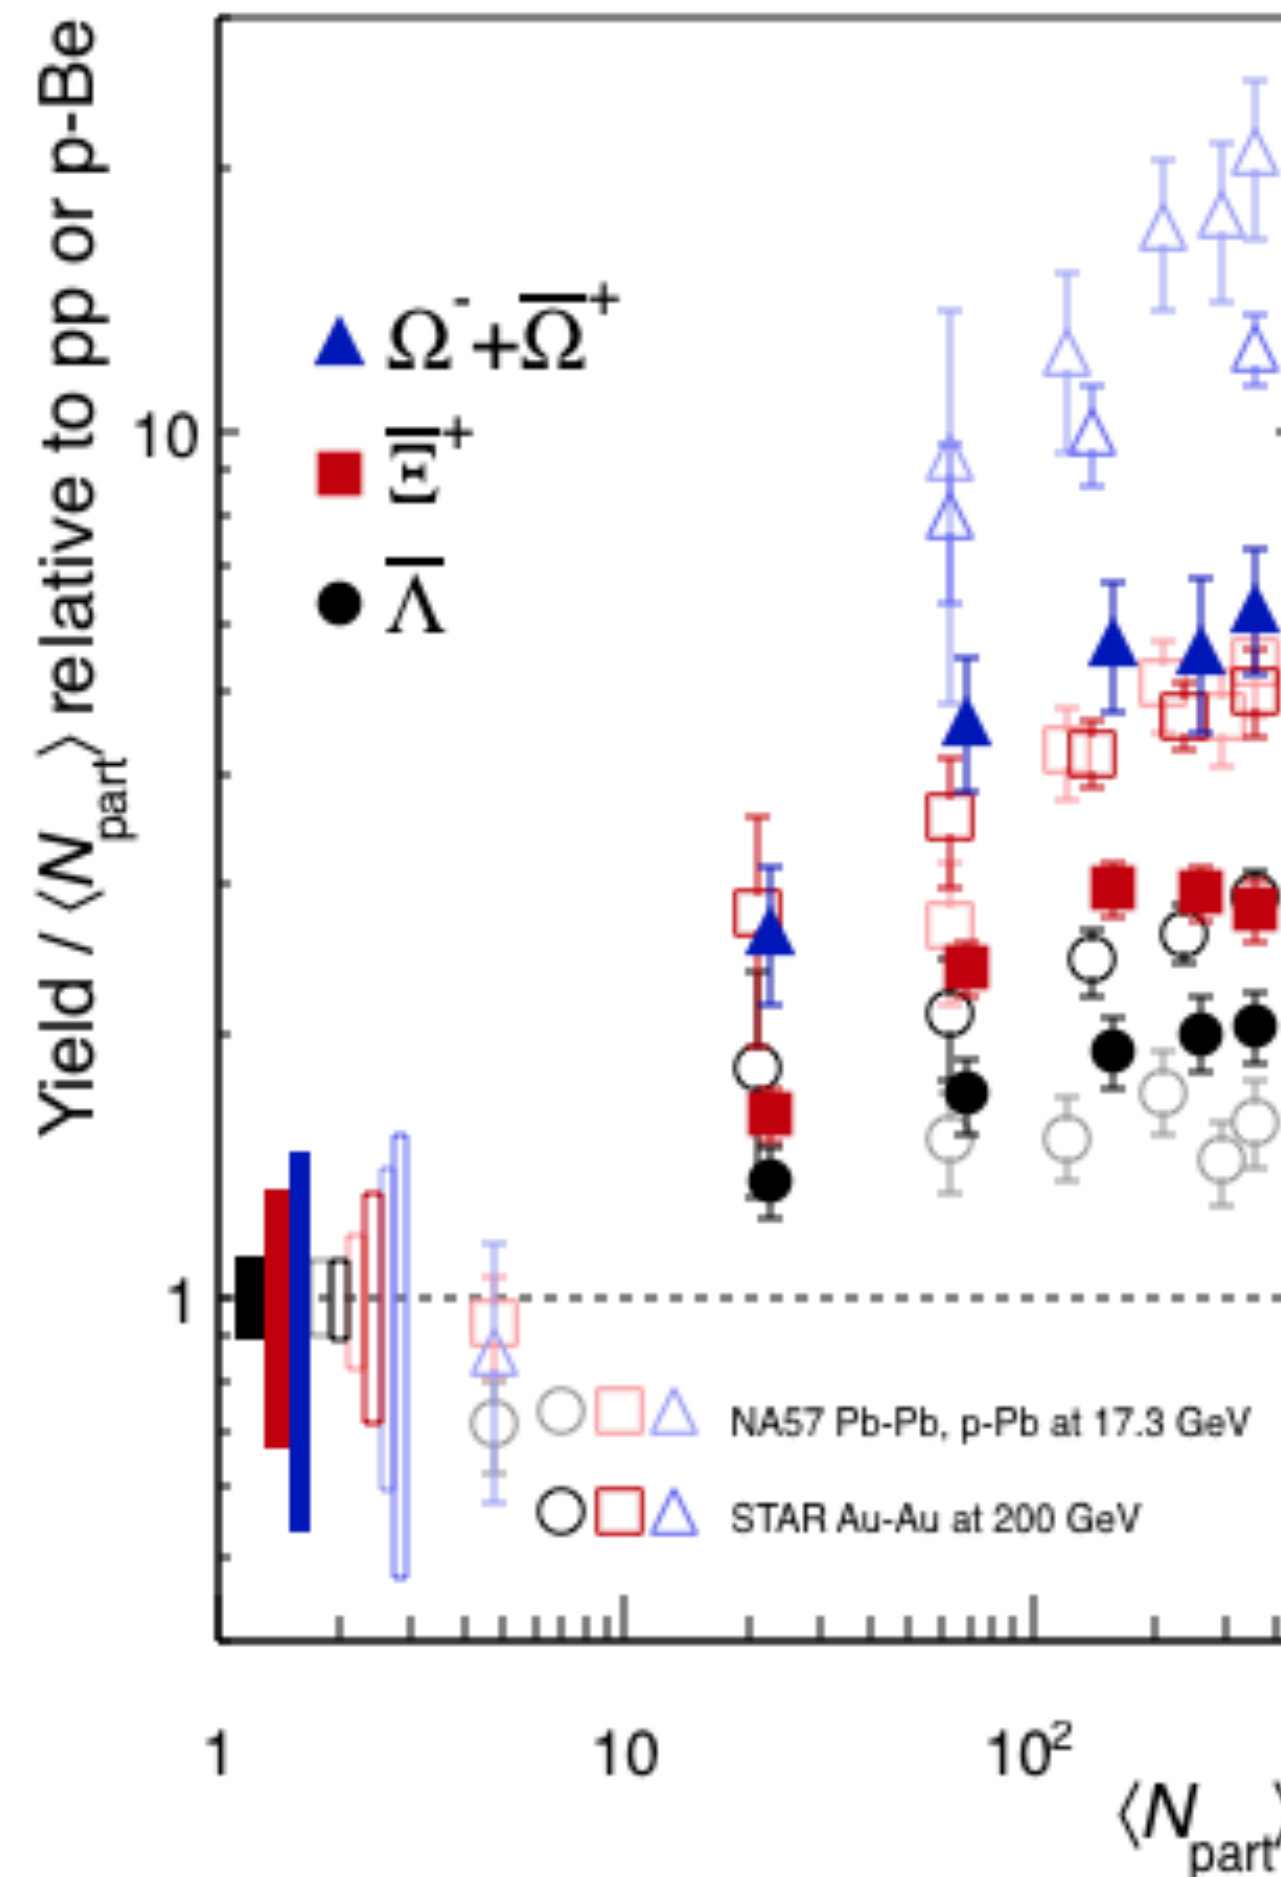

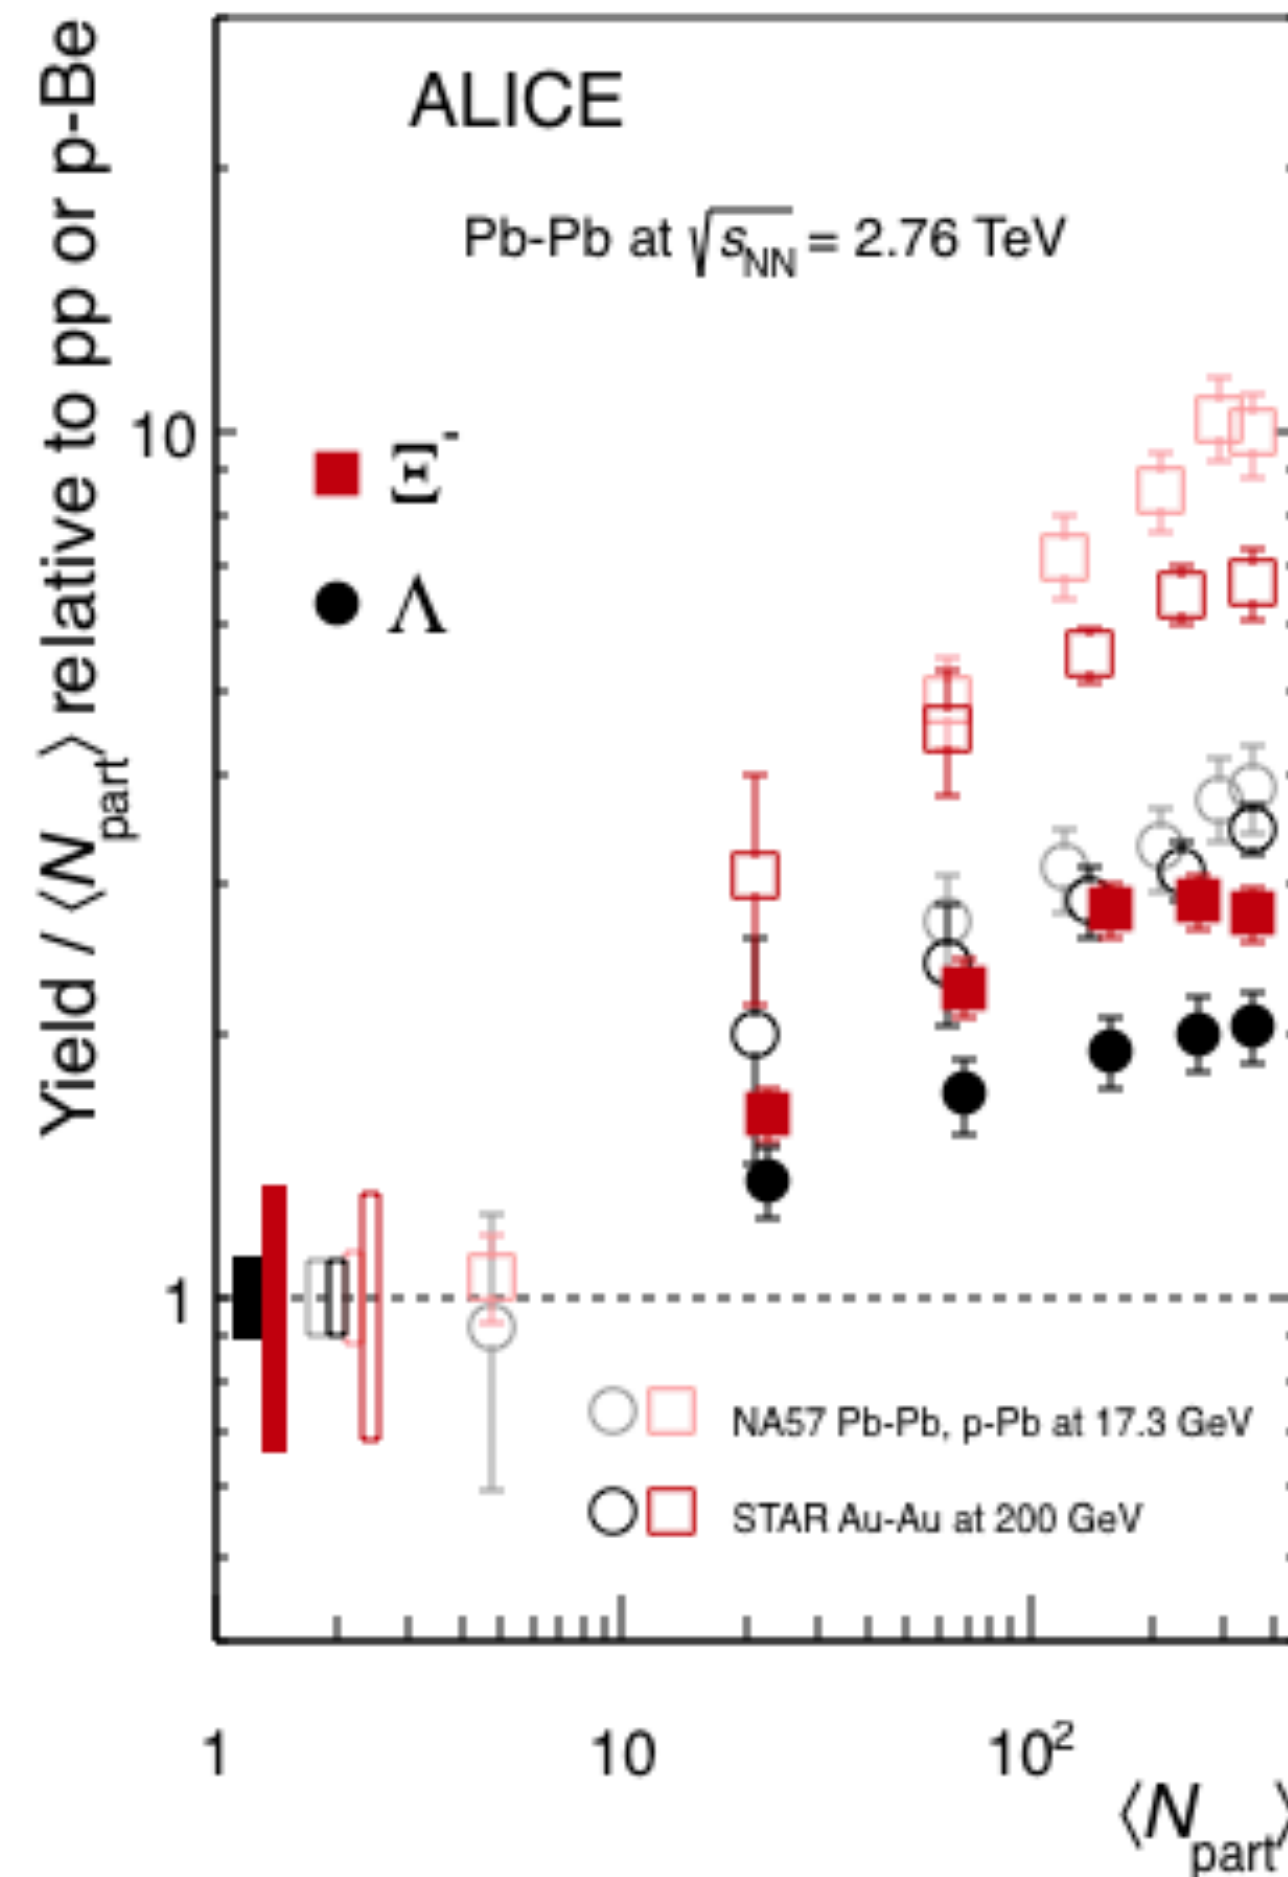

# Strangeness enhancement: QGP signature at the LHC

- Pb-Pb at SPS -  $\sqrt{s_{NN}} = 8.73$  GeV
- Pb-Pb at SPS -  $\sqrt{s_{NN}} = 17.3$  GeV
- Au-Au at RHIC -  $\sqrt{s_{NN}} = 200$  GeV
- Pb-Pb at the LHC -  $\sqrt{s_{NN}} = 2.76$  TeV

At higher energy confirmed the lower enhancement (x6 for the  $\Omega$ ) observed at RHIC

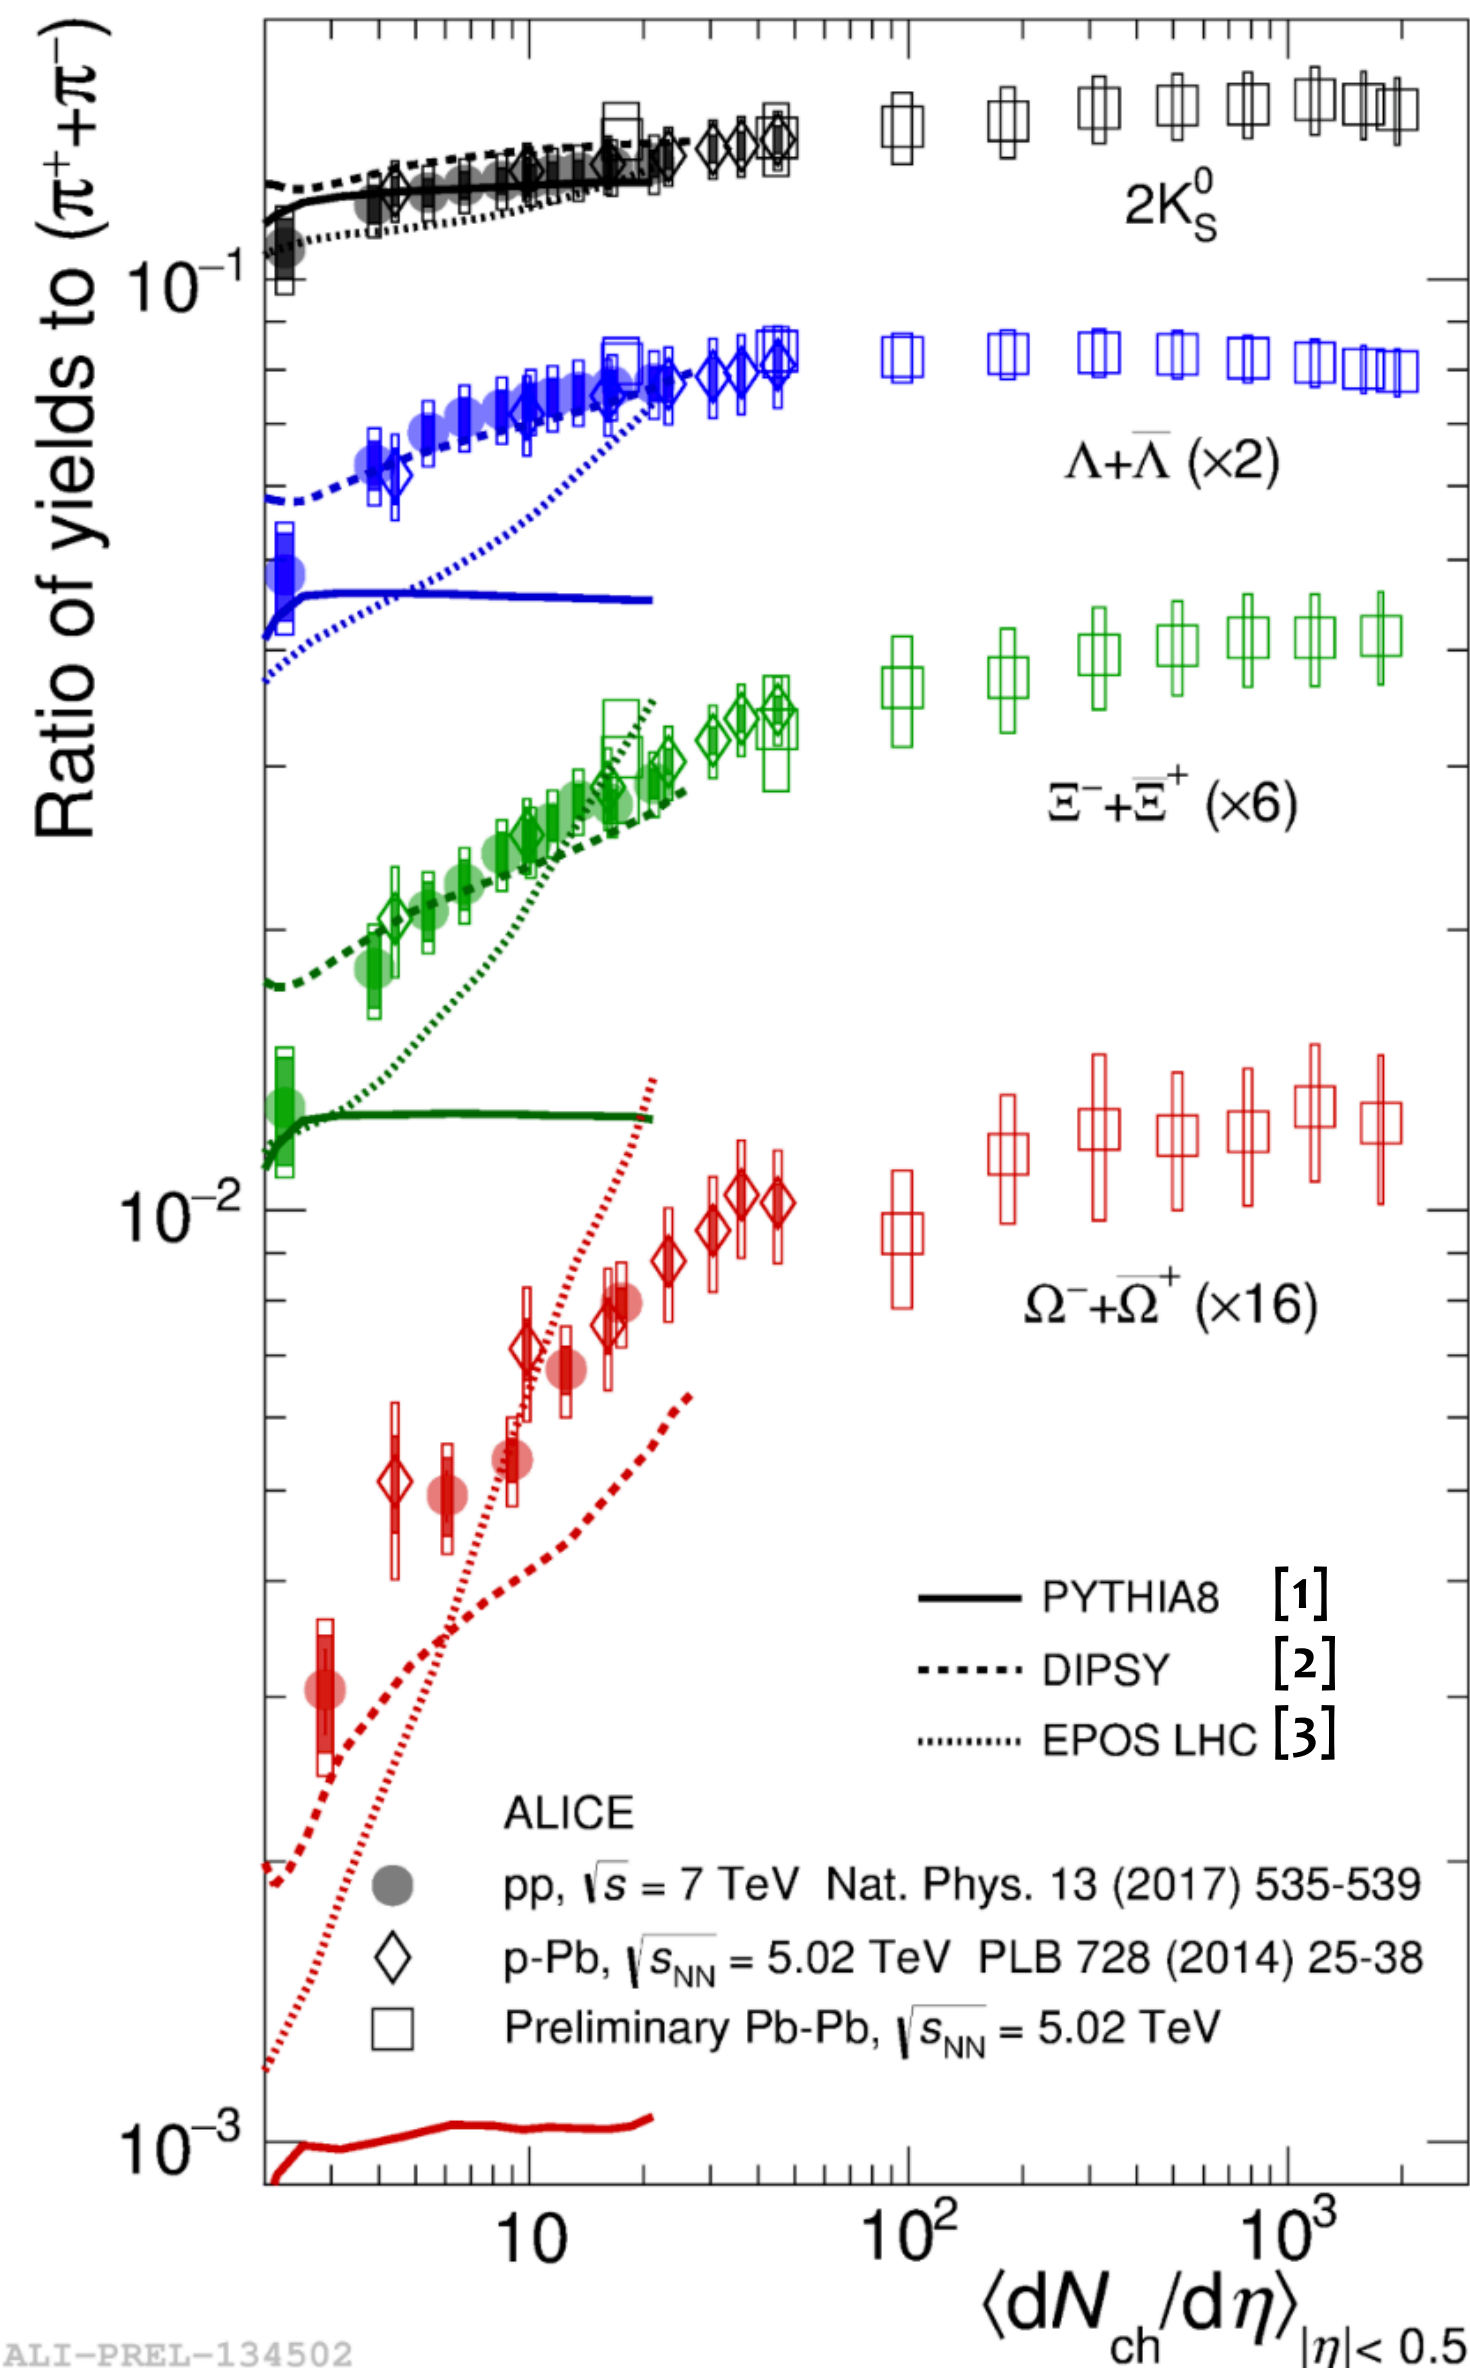

enhancement ↑

centrality →

- Pb-Pb at the LHC -  $\sqrt{s_{NN}} = 2.76$  TeV
- Au-Au at RHIC -  $\sqrt{s_{NN}} = 200$  GeV
- Pb-Pb at SPS -  $\sqrt{s_{NN}} = 17.3$  GeV
- Pb-Pb at SPS -  $\sqrt{s_{NN}} = 8.75$  GeV
- Hyperon hierarchy predicted as a signature for QGP confirmed at different energy regimes
- Lower enhancement when collision energy increases

# Strangeness enhancement: from small systems to Pb-Pb

- Enhanced production of **strange and multi-strange particles** observed in high-multiplicity pp collisions
- multiplicity dependence of strangeness production is **strikingly similar in pp and p-Pb** and follow the trend of the values corresponding to central Pb-Pb
- MC predictions do not describe satisfactorily the experimental data
  - ➔ **strong disagreement with PYTHIA8** → Color Reconnection among Multiple Parton Interactions does not help
  - ➔ **EPOS LHC** → does not match the data straight away
  - ➔ better agreement with **DIPSY** → BUT deviation for  $\Omega$  and too much stress on baryon production

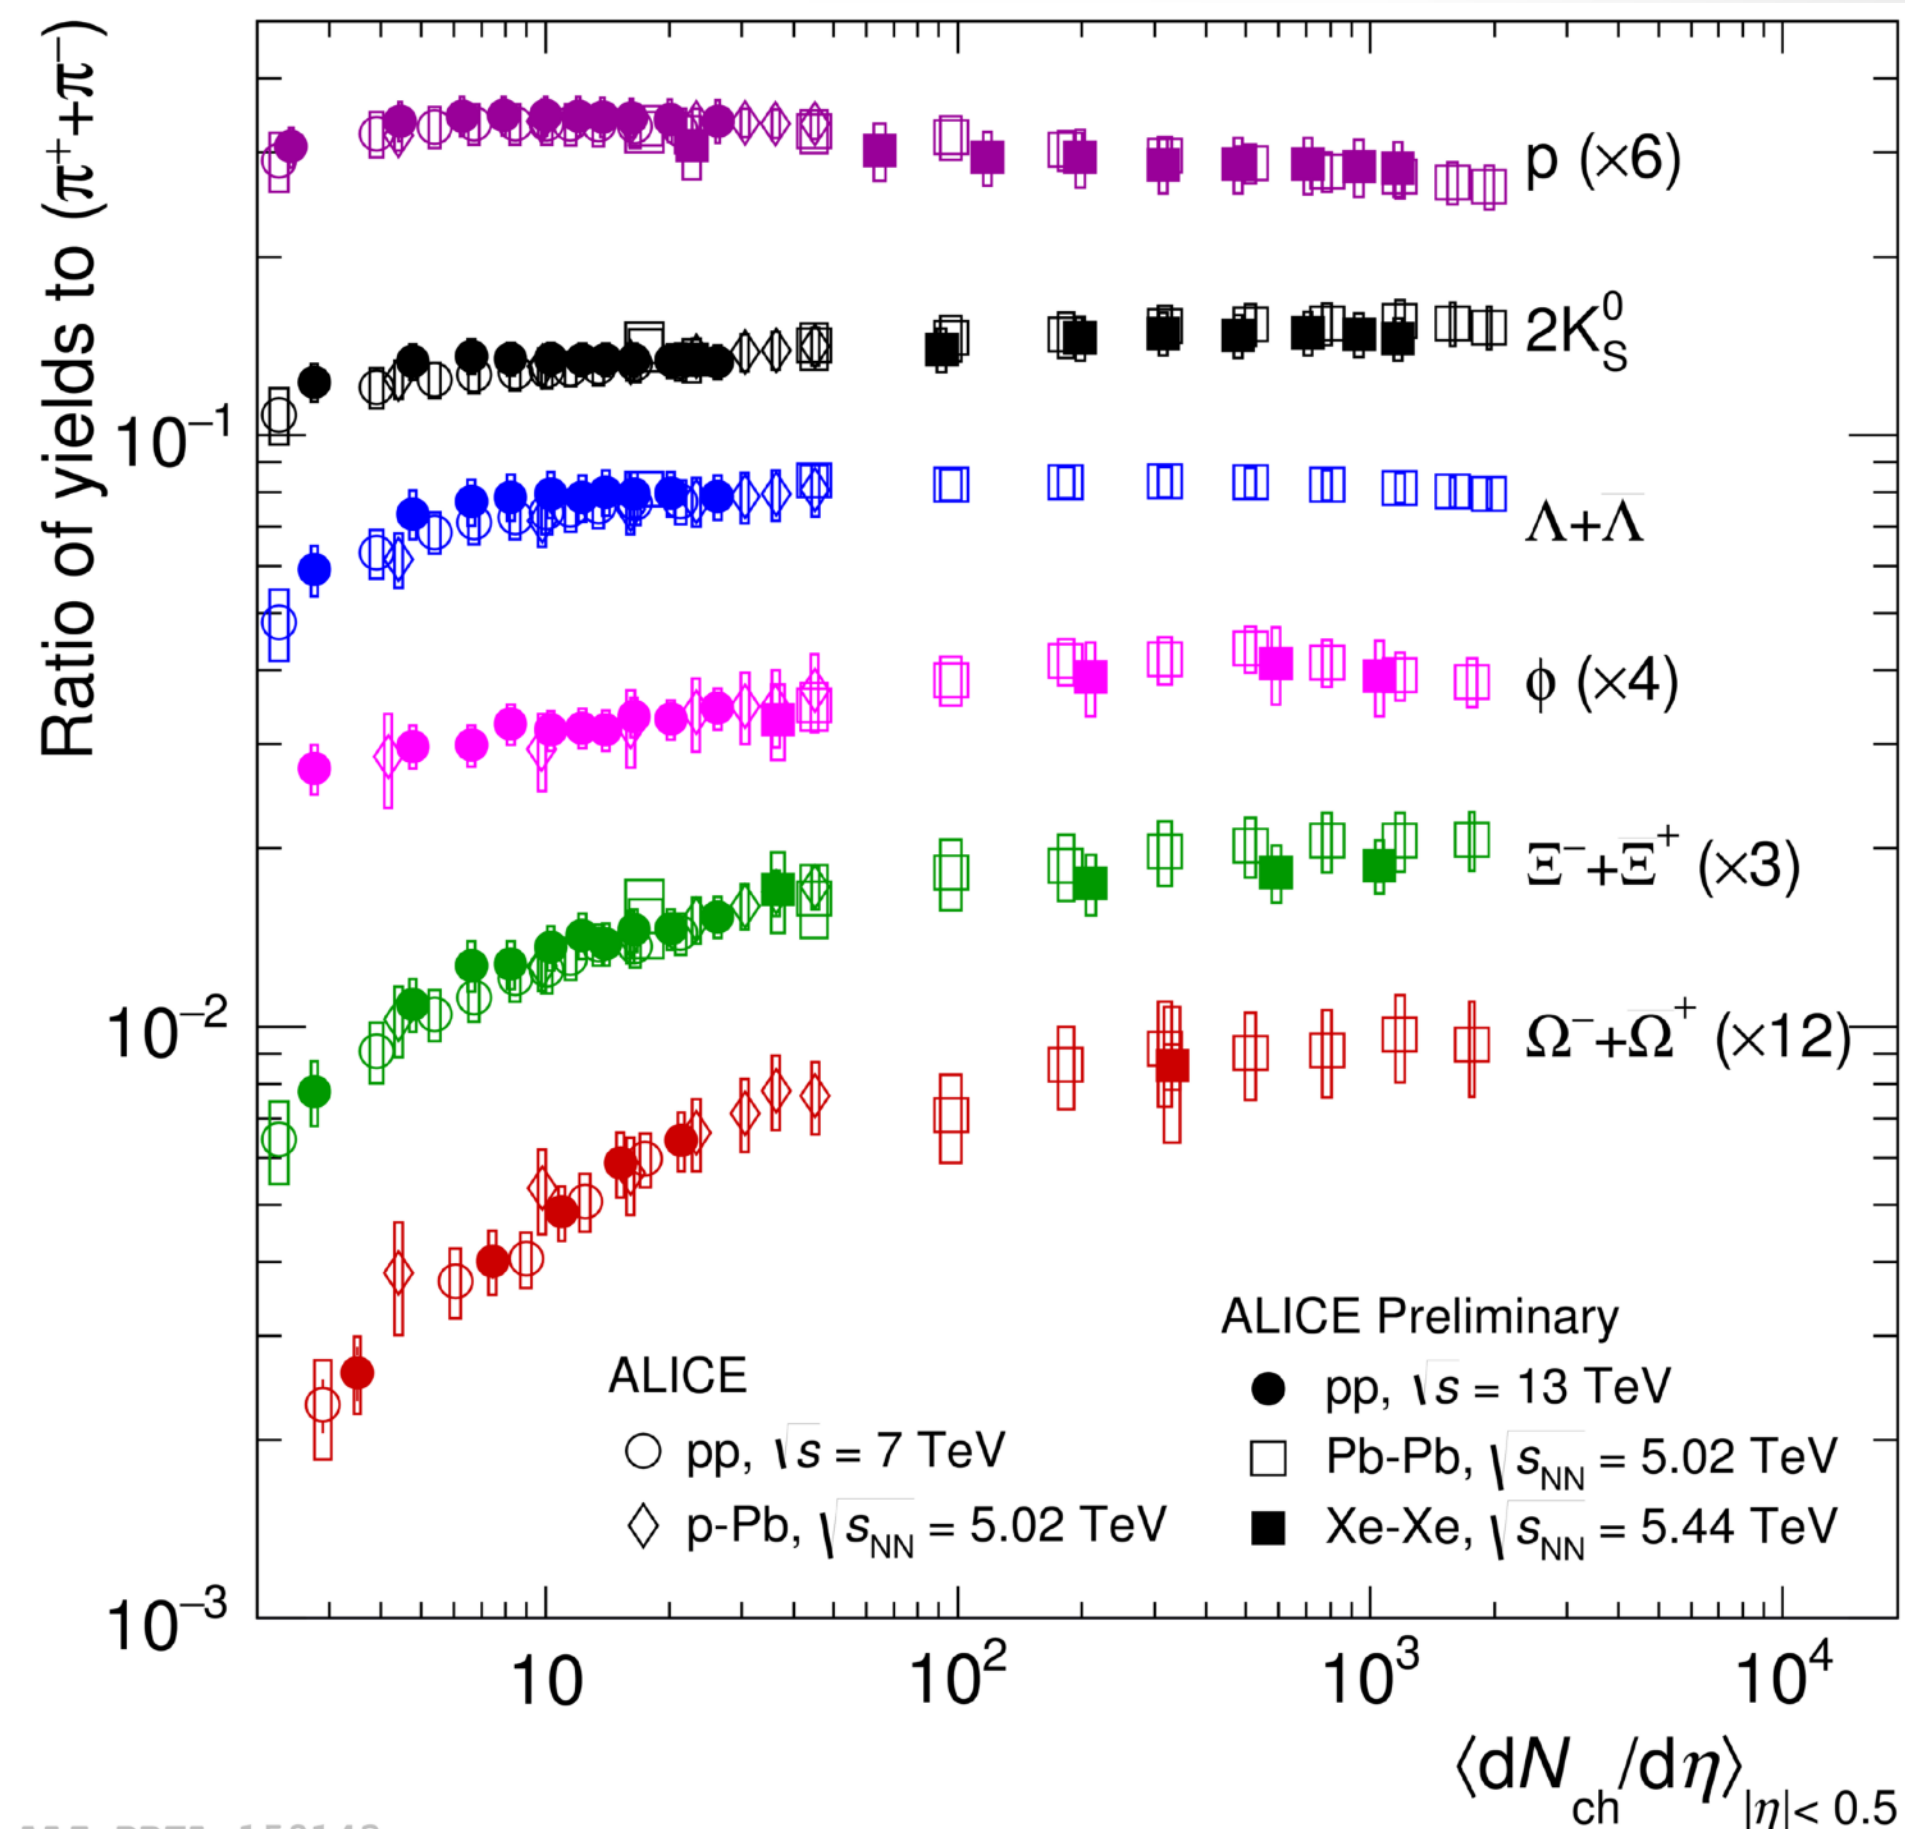

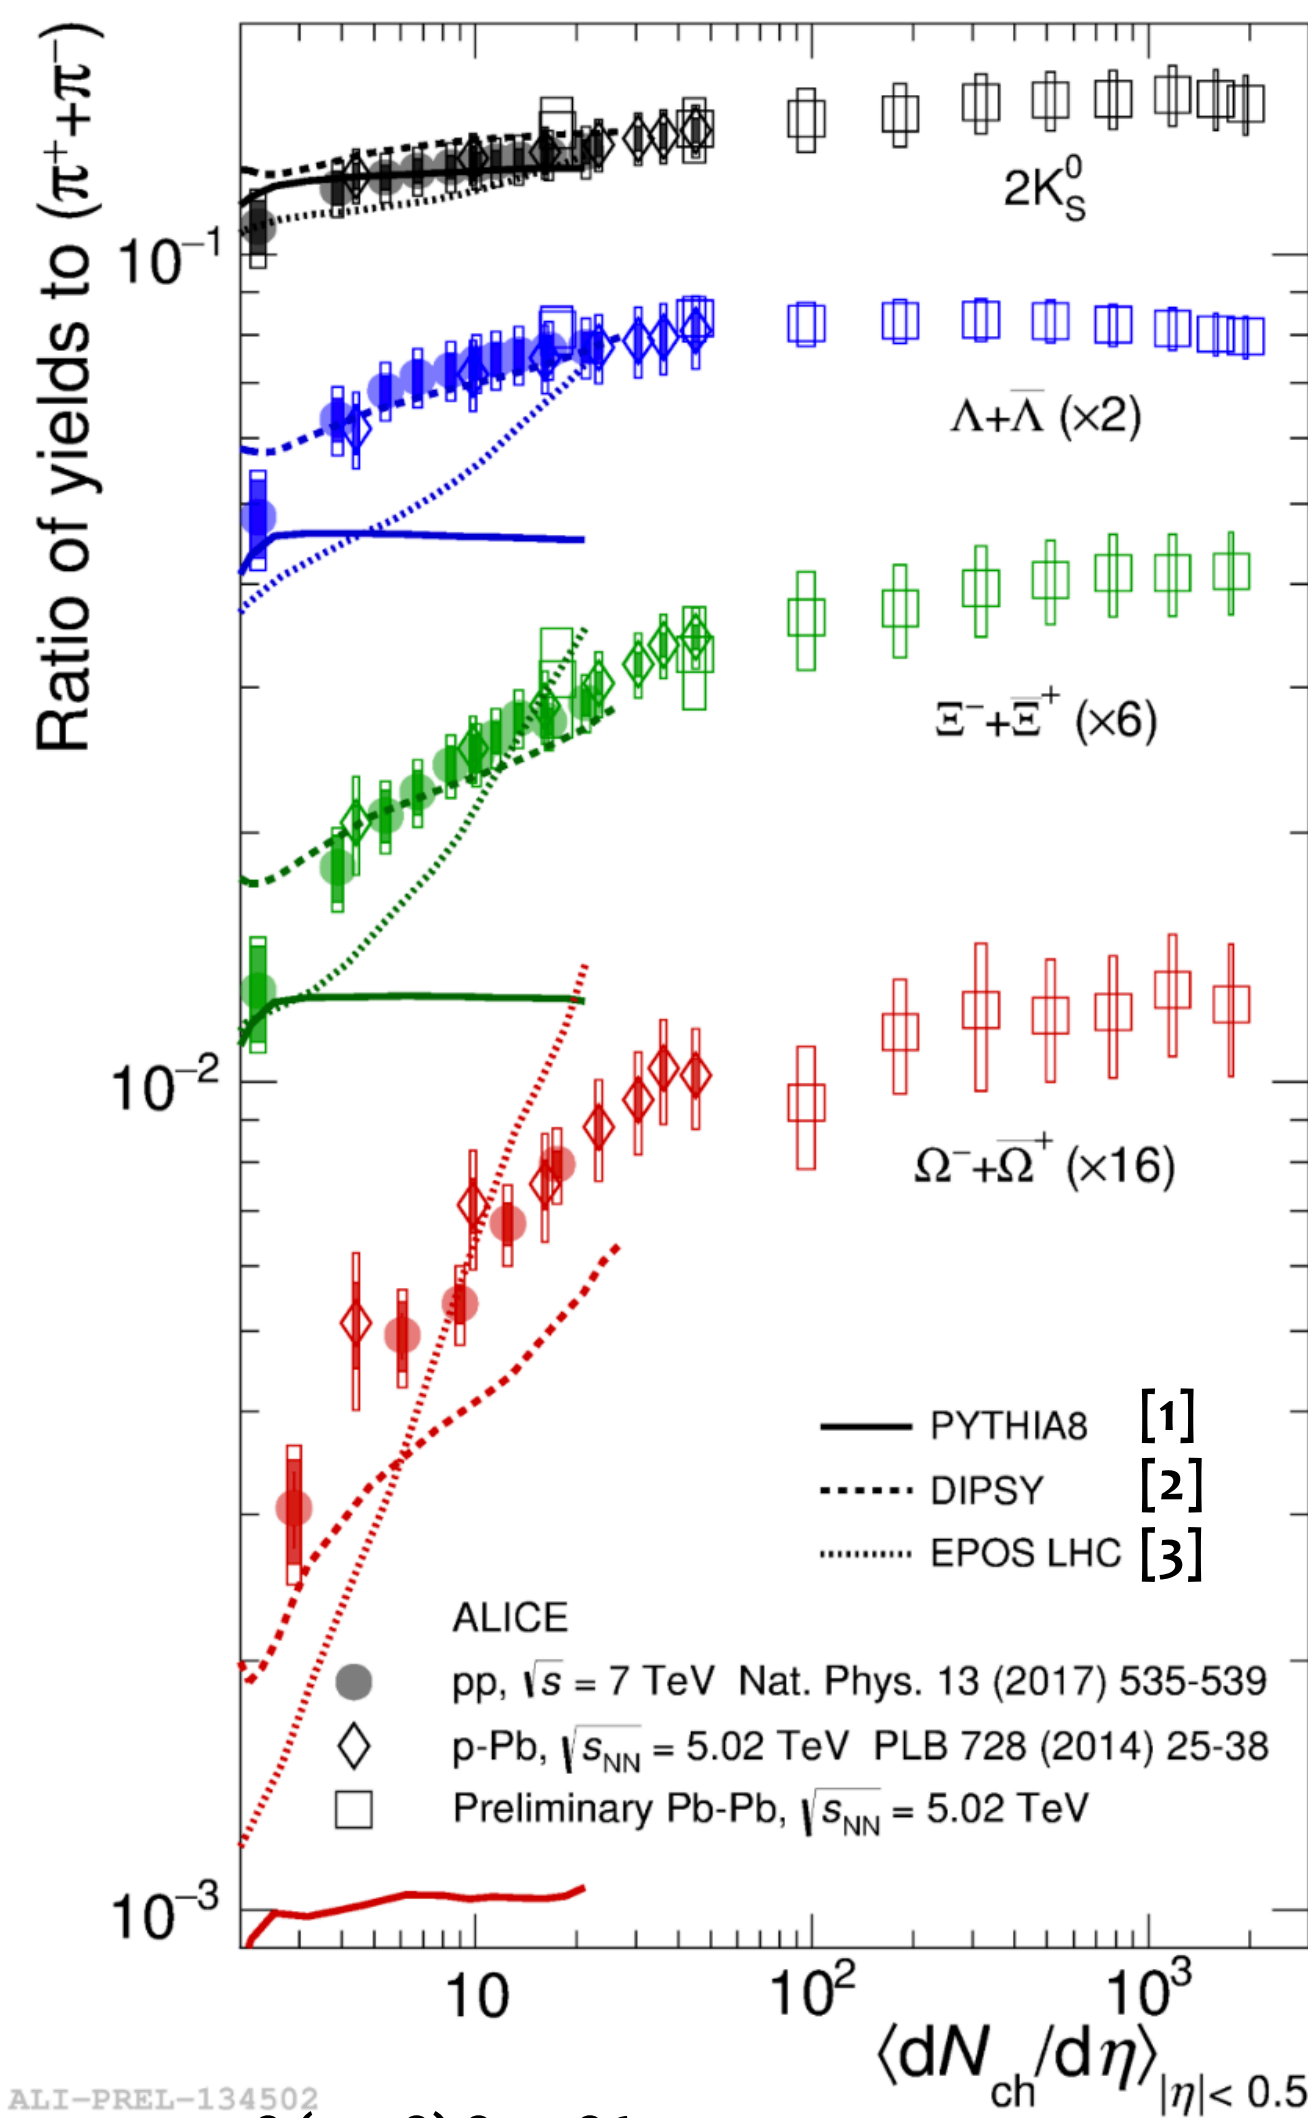

[1] Comput. Phys. Commun. 178 (2008) 852–867

# Strangeness enhancement at the LHC top energy

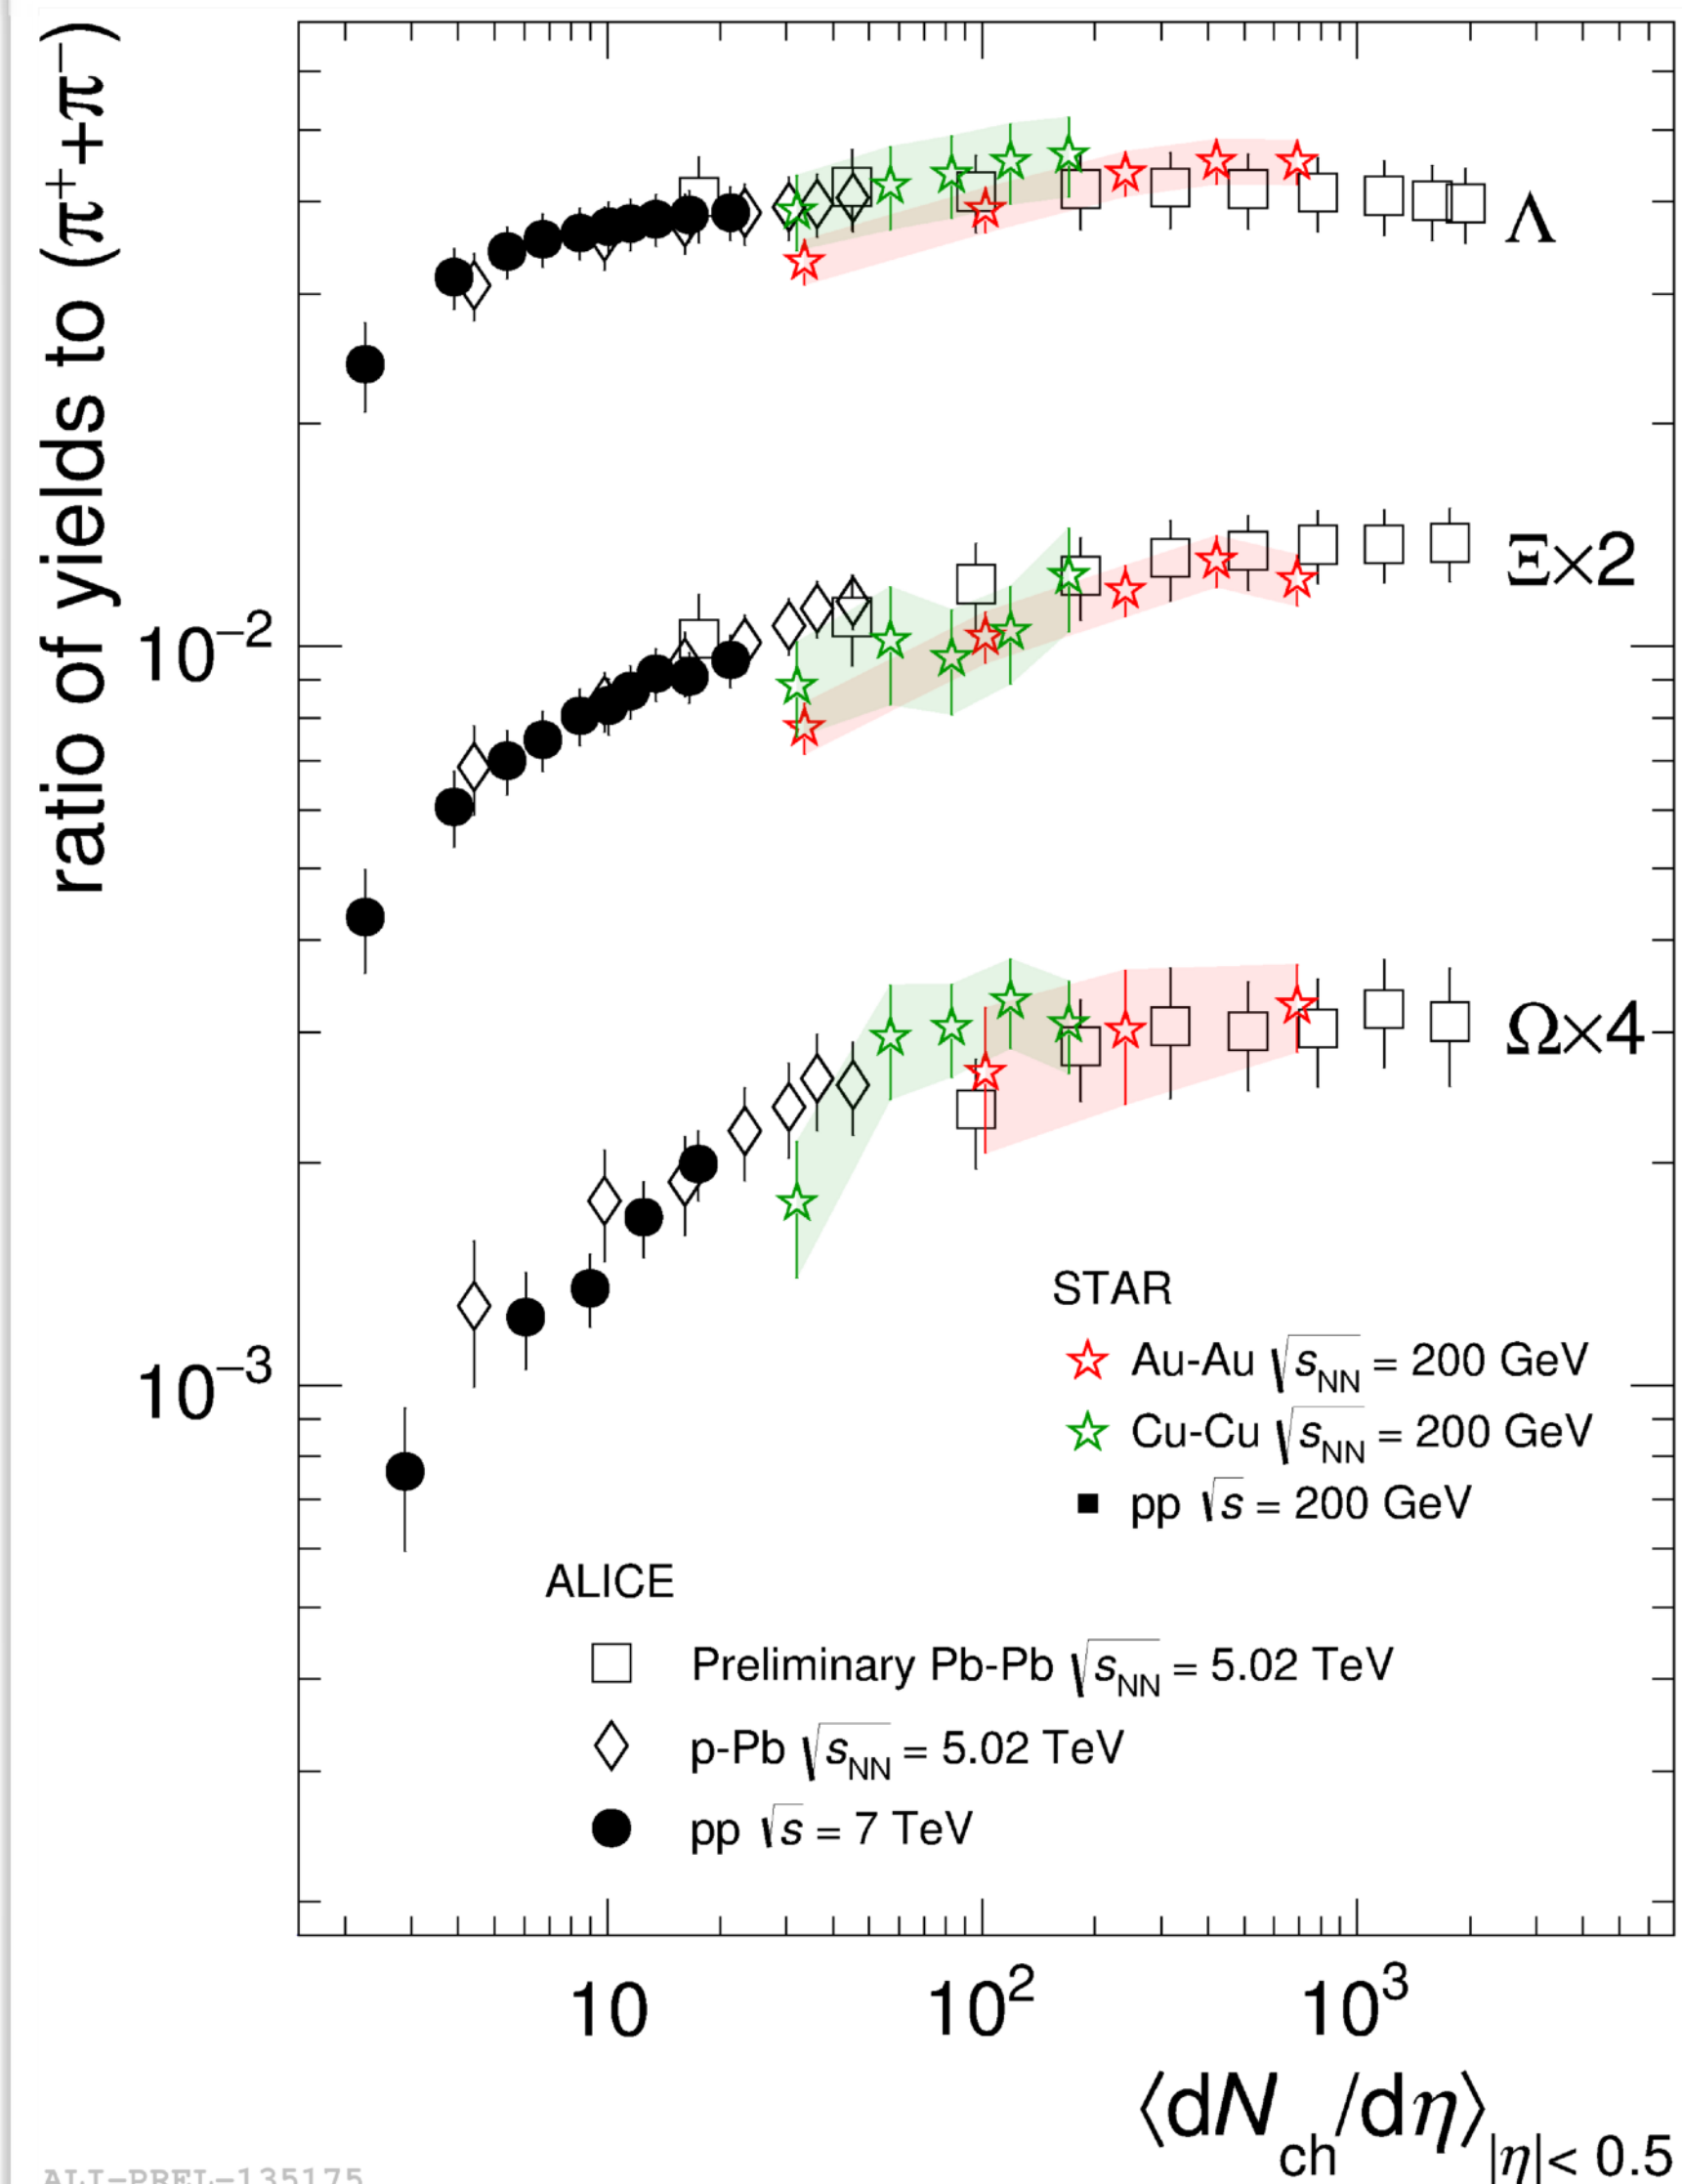

Latest news

ALI-PREL-159143

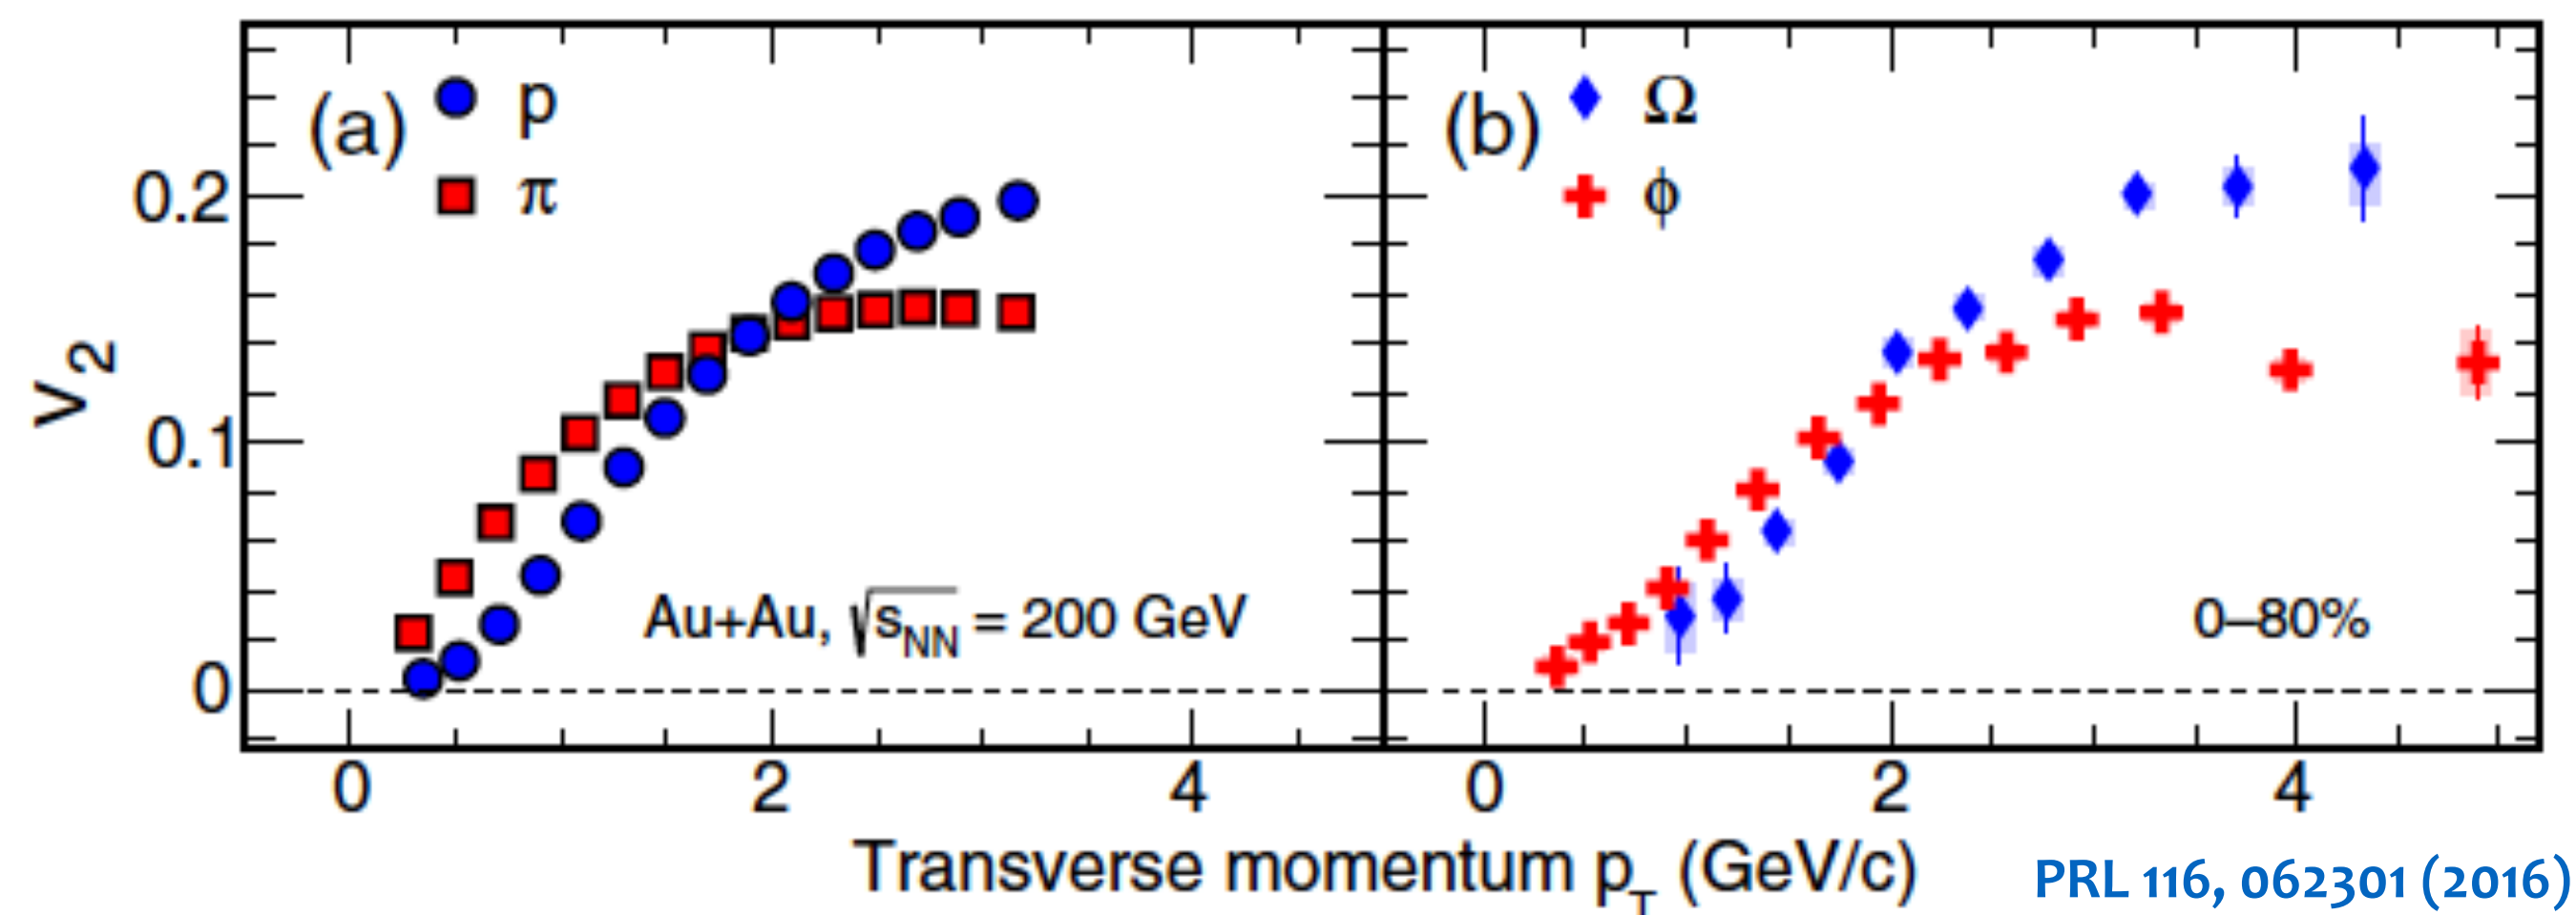

Wrap up of measurements available so far: new results from LHC-Run2 for **pp collisions at 13 TeV** and **Xe-Xe collisions at 5.44 TeV**

- [1] Comput. Phys. Commun. 178 (2008) 852–867  
 [2] JHEP 08 (2011) 103  
 [3] Phys. Rev. C 92, 034906 (2015)

- High precision measurement at the **LHC** in fair agreement with **STAR** results at high multiplicity
- **Only multiplicity plays a role?** neither energy nor system dependence observed
- Measurements in small system at RHIC could help to understand the experimental hints

# $v_2$ measurements with STAR

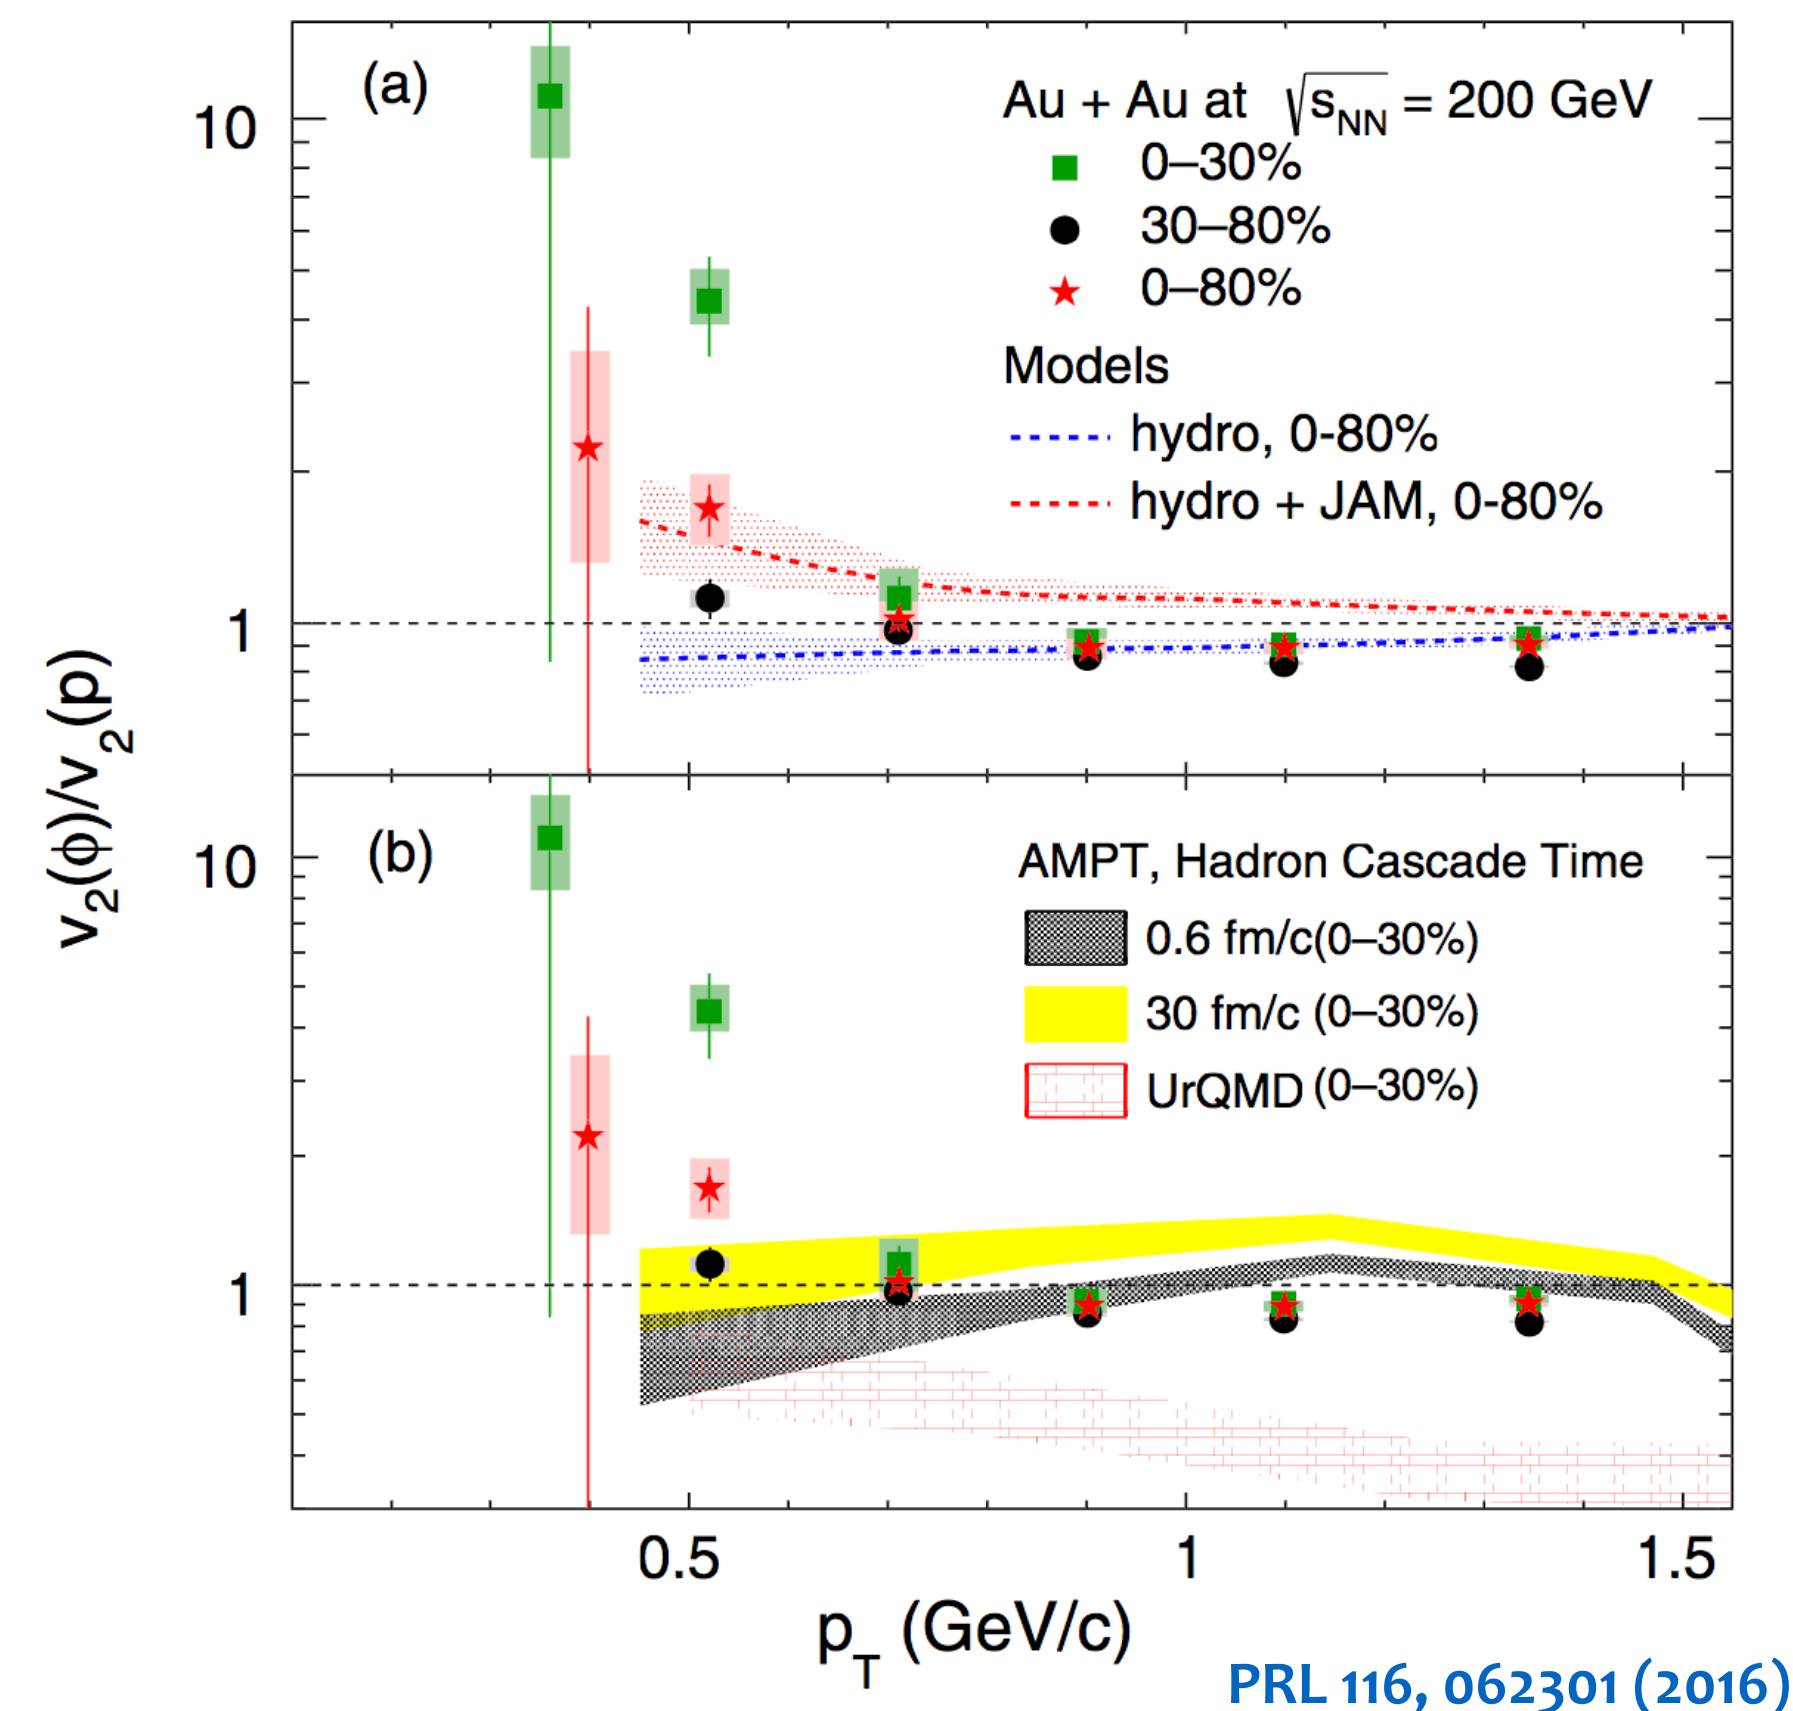

- Same  $v_2$  features observed for **strange and non-strange** hadrons
  - mass ordering
  - baryon/meson splitting

Considering the cross section  
 $\rightarrow v_2$  driven by initial spatial anisotropy

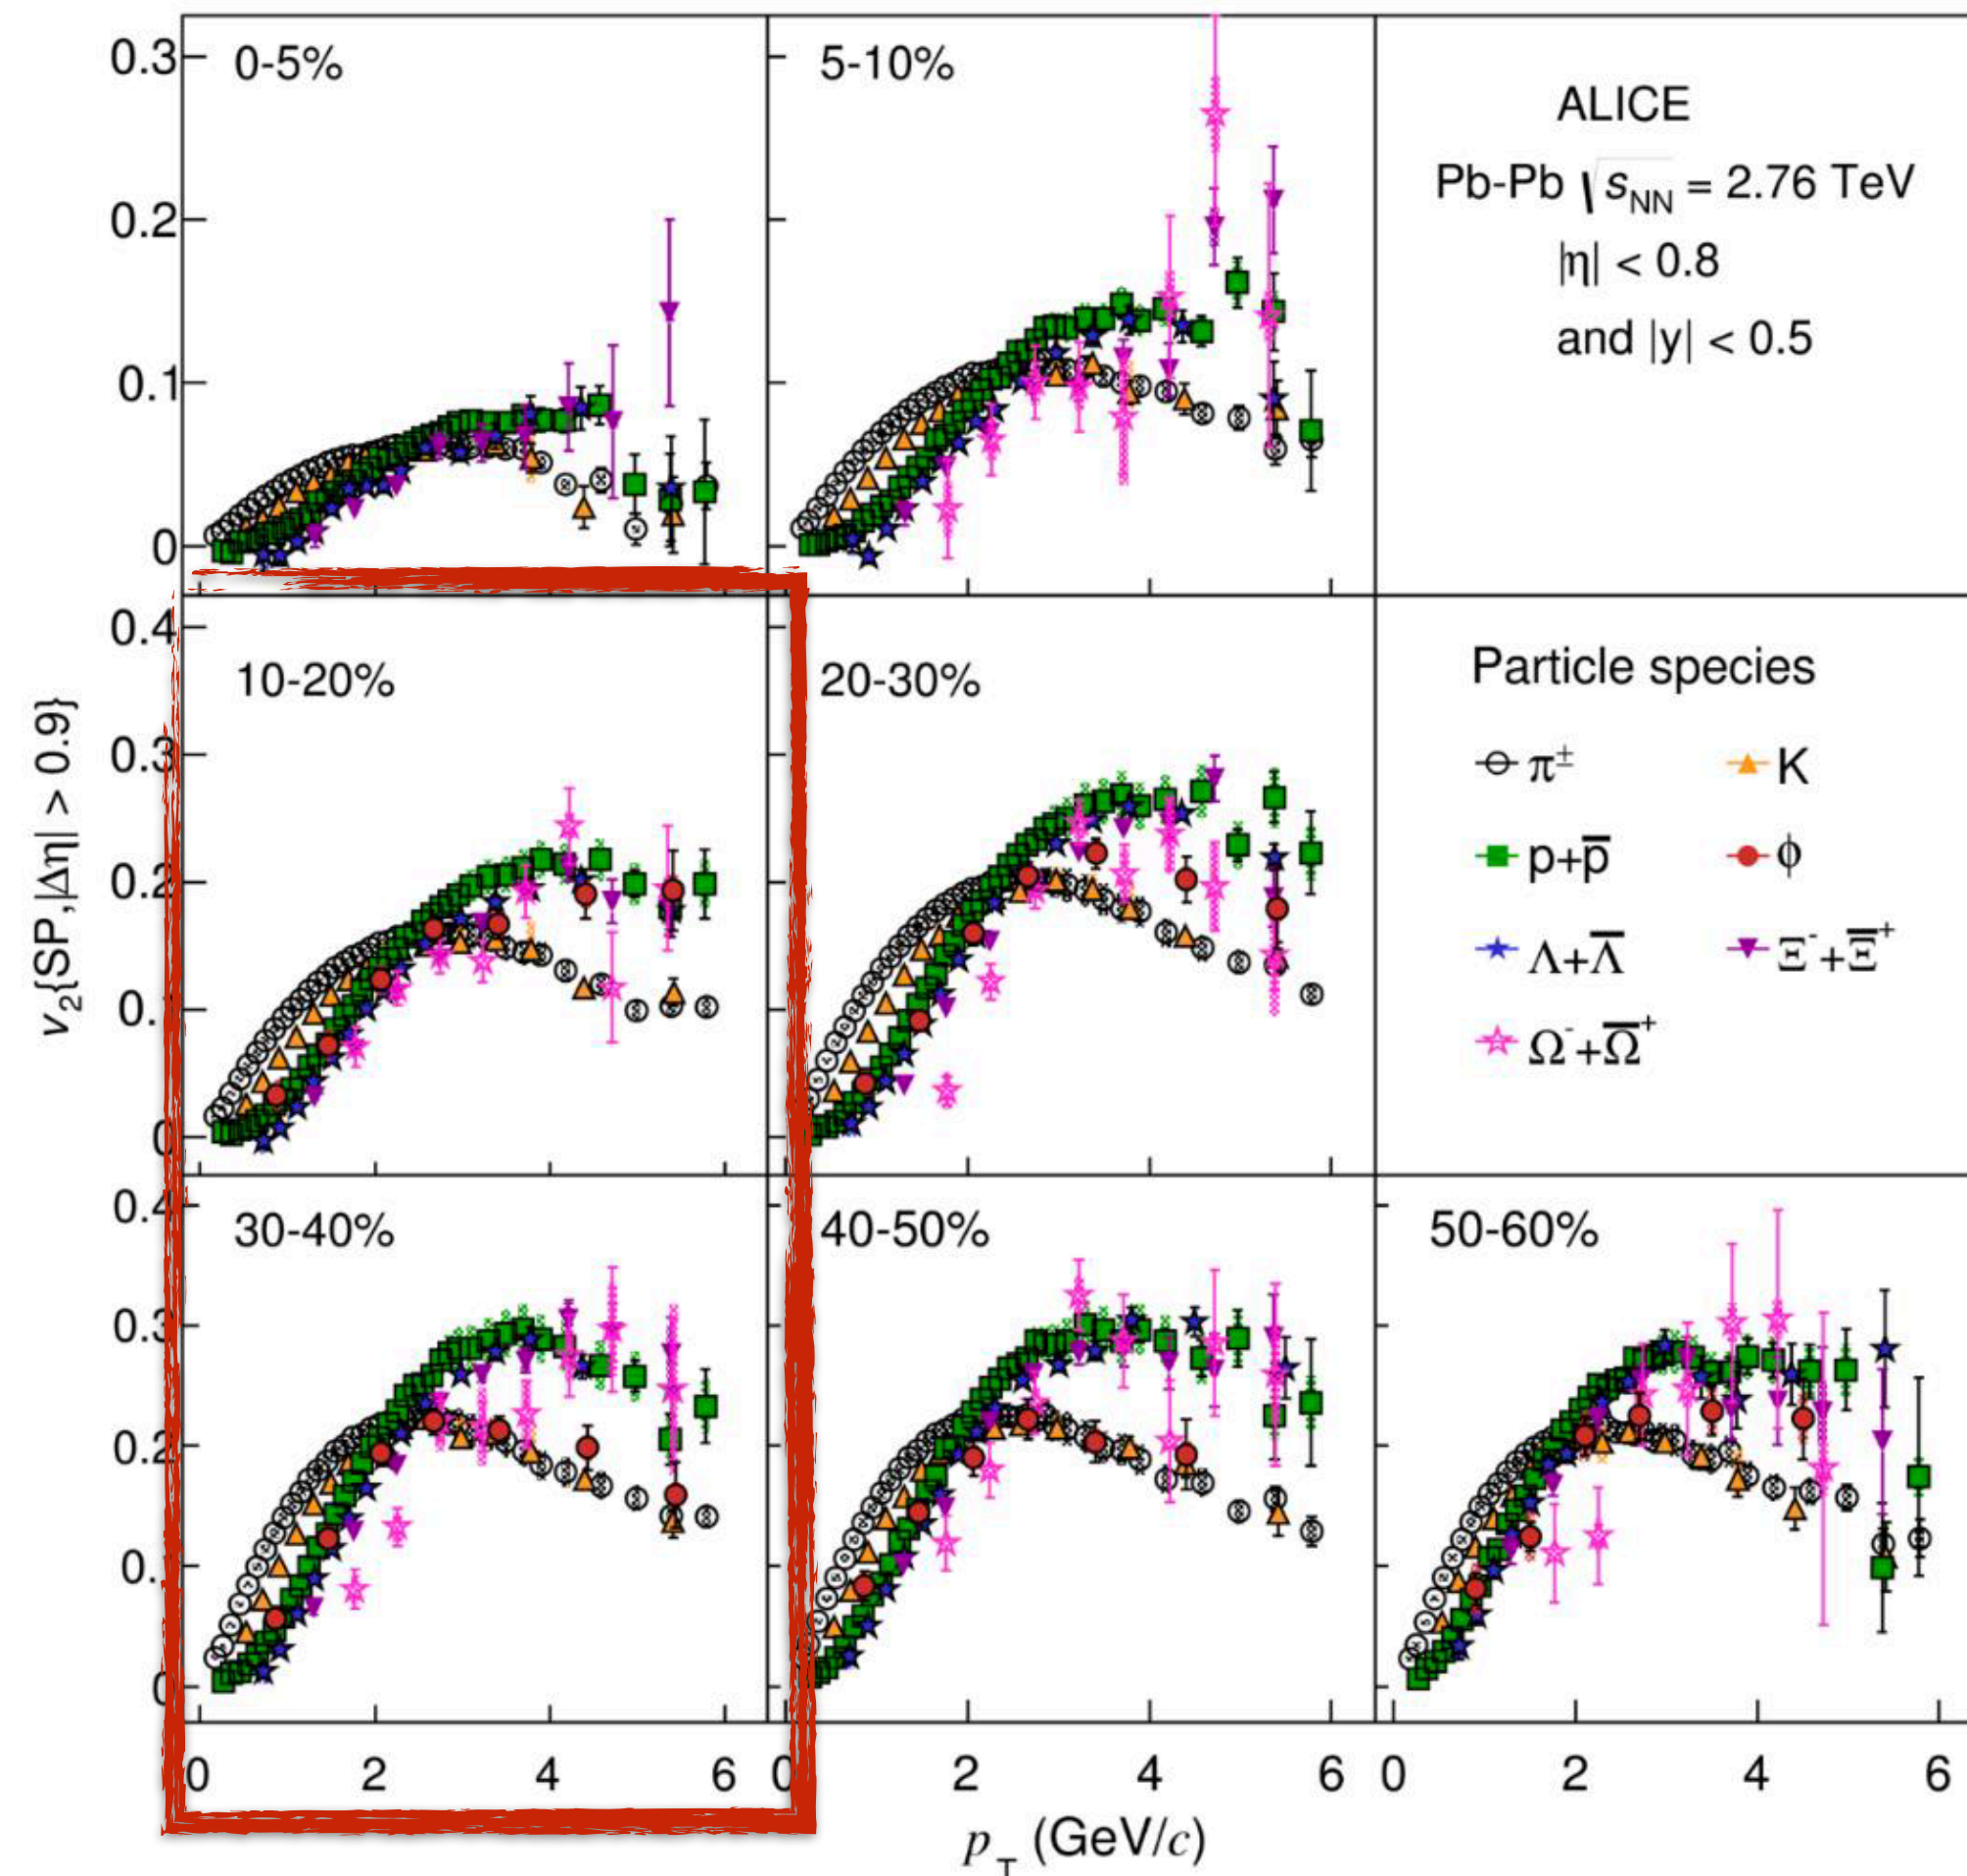

Data favours hydro at low  $p_T$  and coalescence at mid- $p_T$

- Larger ratio at low  $p_T$ : mass ordering breakdown
- comparison with models (0-30%): with increasing hadronic cascade time, the  $v_2(\phi)/v_2(p)$  ratio increases  
 $\rightarrow$  **more hadronic rescattering for protons?**

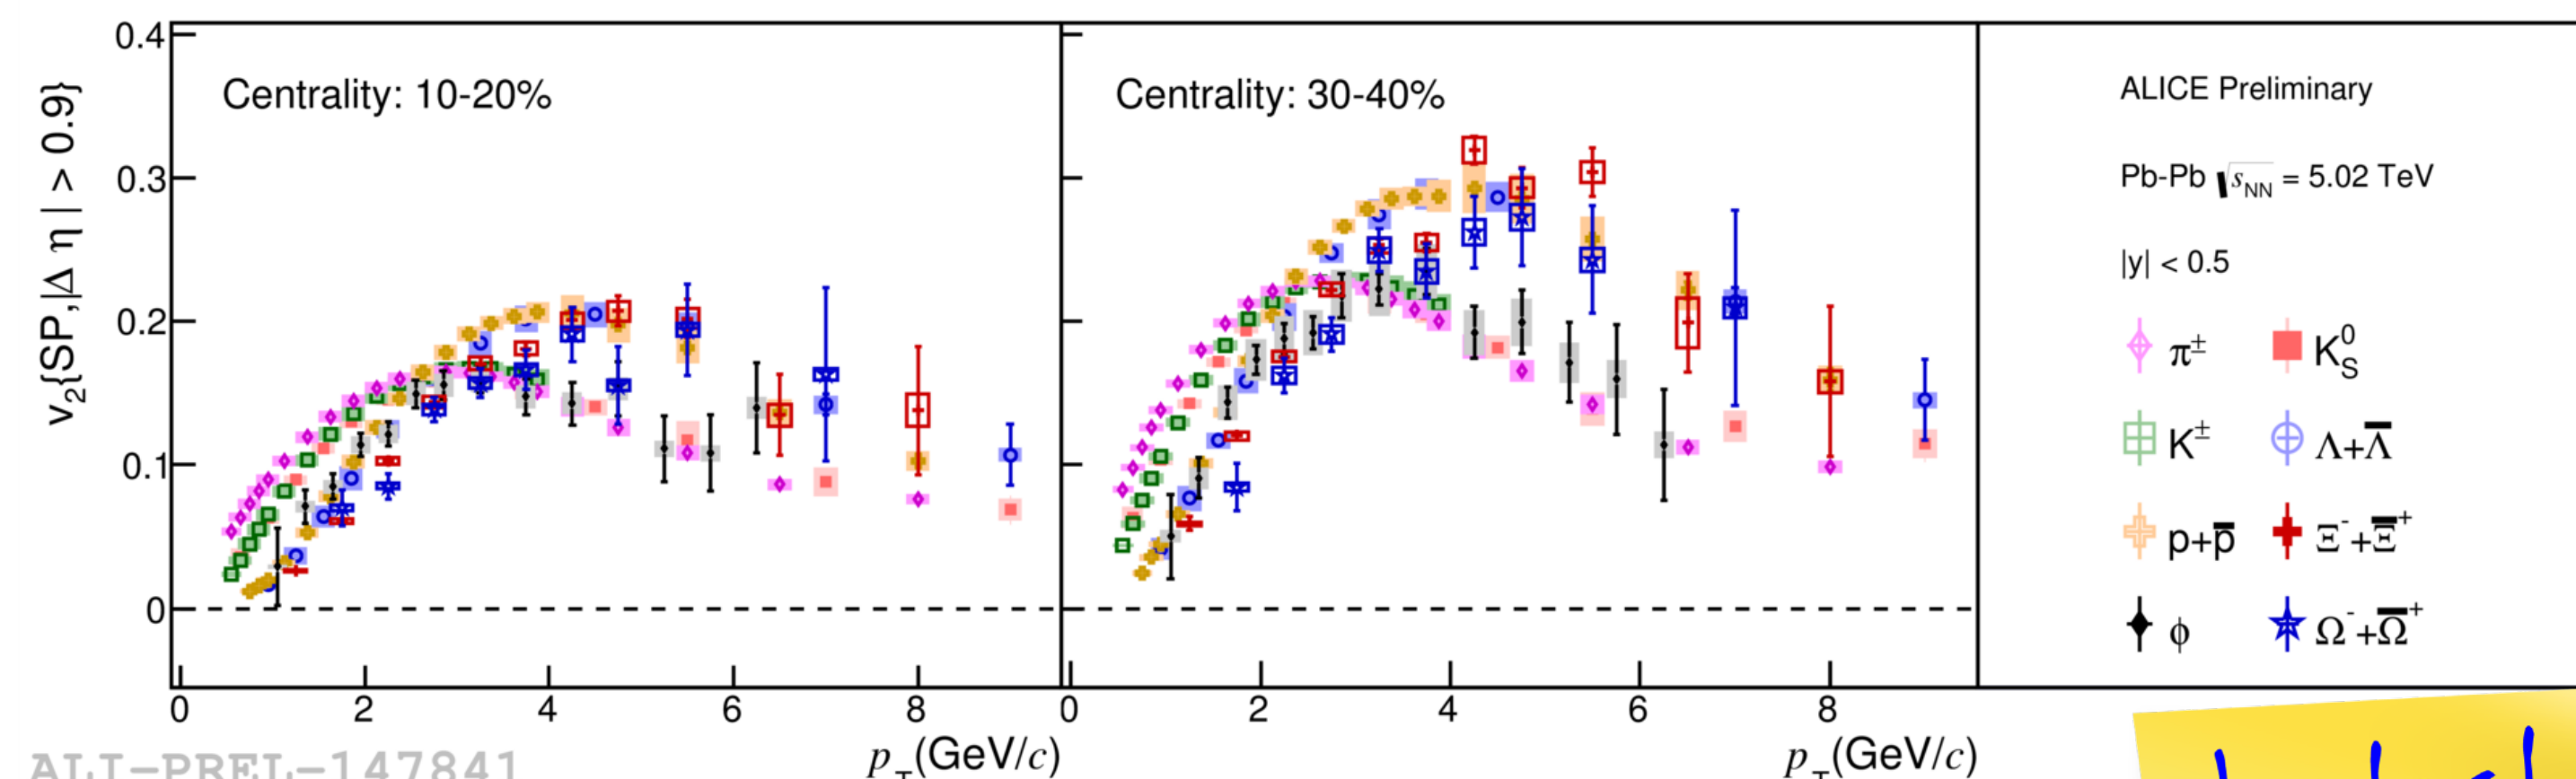

# $v_2$ measurements with ALICE

## LHC Run1

JHEP 06 (2015) 190

## Multistrange baryon results from LHC Run2

Latest news

- Extended kinematic range of the measurement.
- Mass ordering for  $p_T < 2$  GeV/c.
- Error reduced: better constraint off the theoretical models.
- Run 1 trend confirmed.

Data favours hydro at low  $p_T$  and coalescence at mid- $p_T$

- (Hyper-)nuclei are formed by protons ( $\Lambda$ ) and neutrons which have similar velocities after the freeze-out

- Hadrons emitted from the interaction region in statistical equilibrium once the *chemical freeze-out* temperature is reached.
- Production yields estimation for central heavy-ion collisions at LHC energies

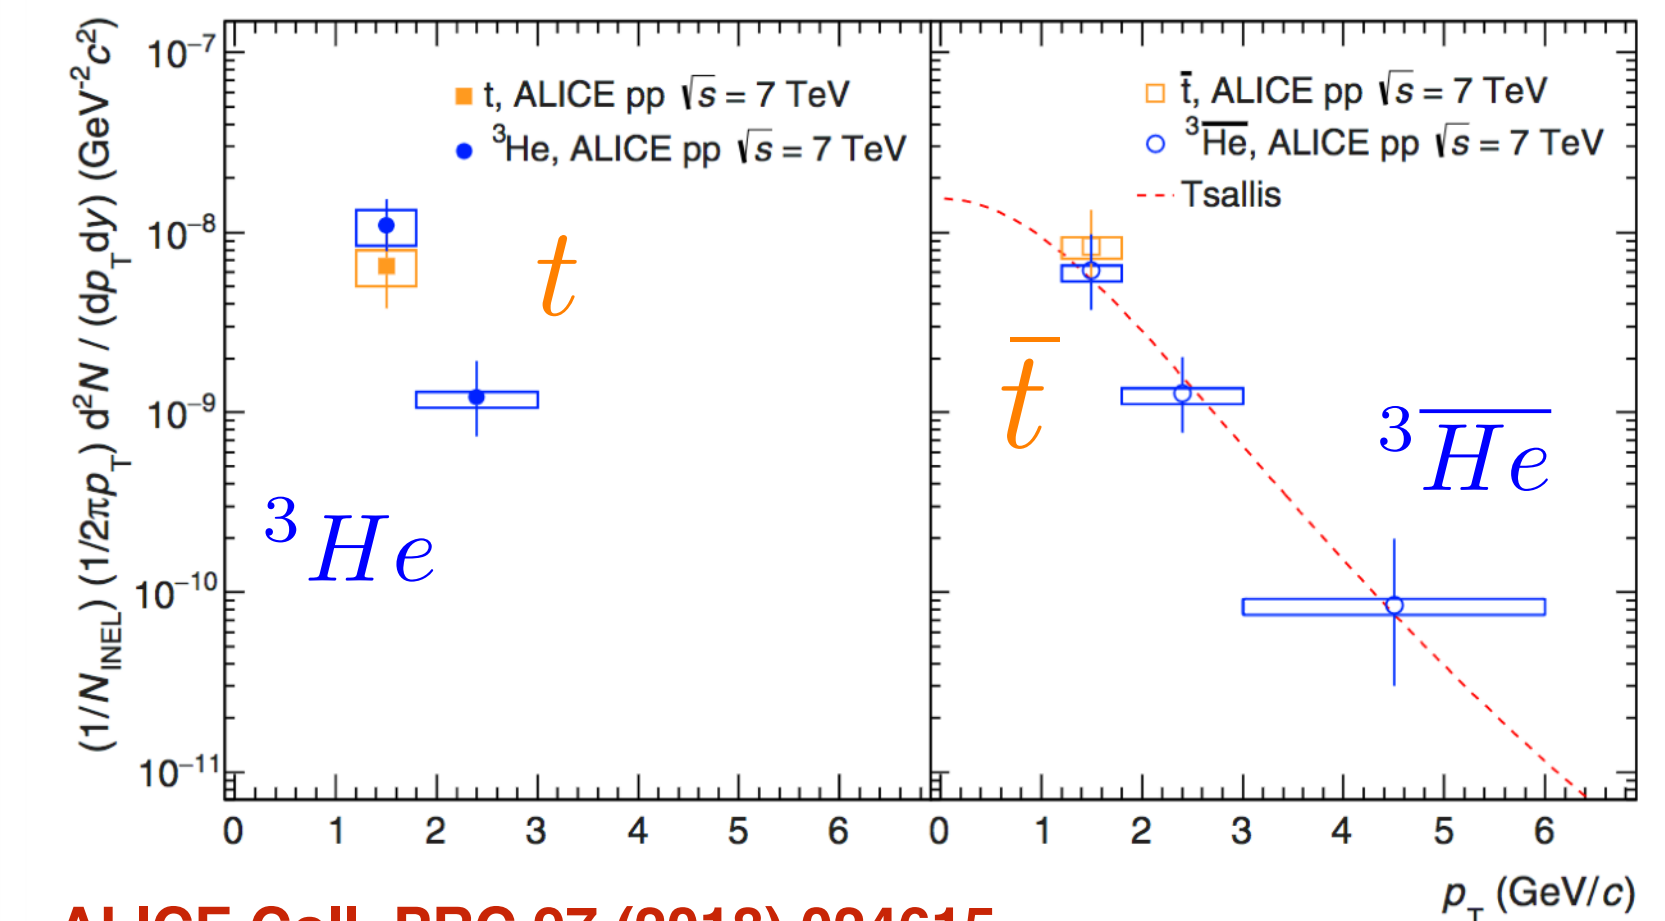

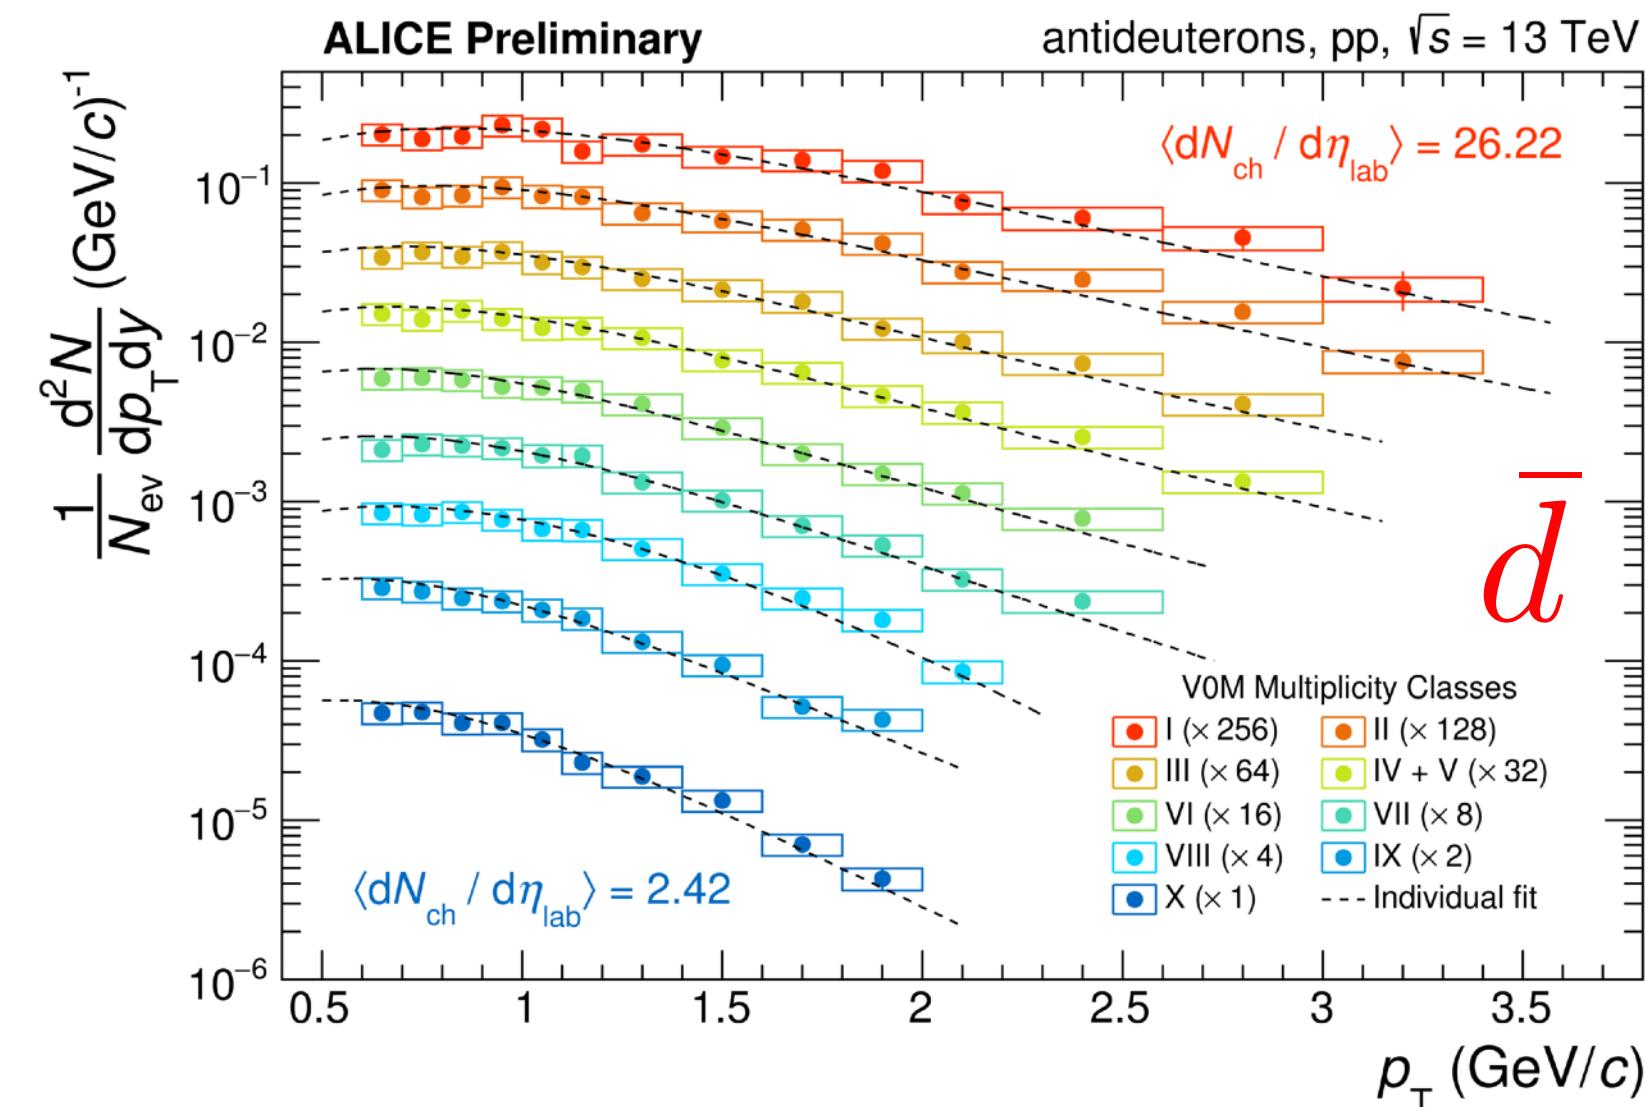

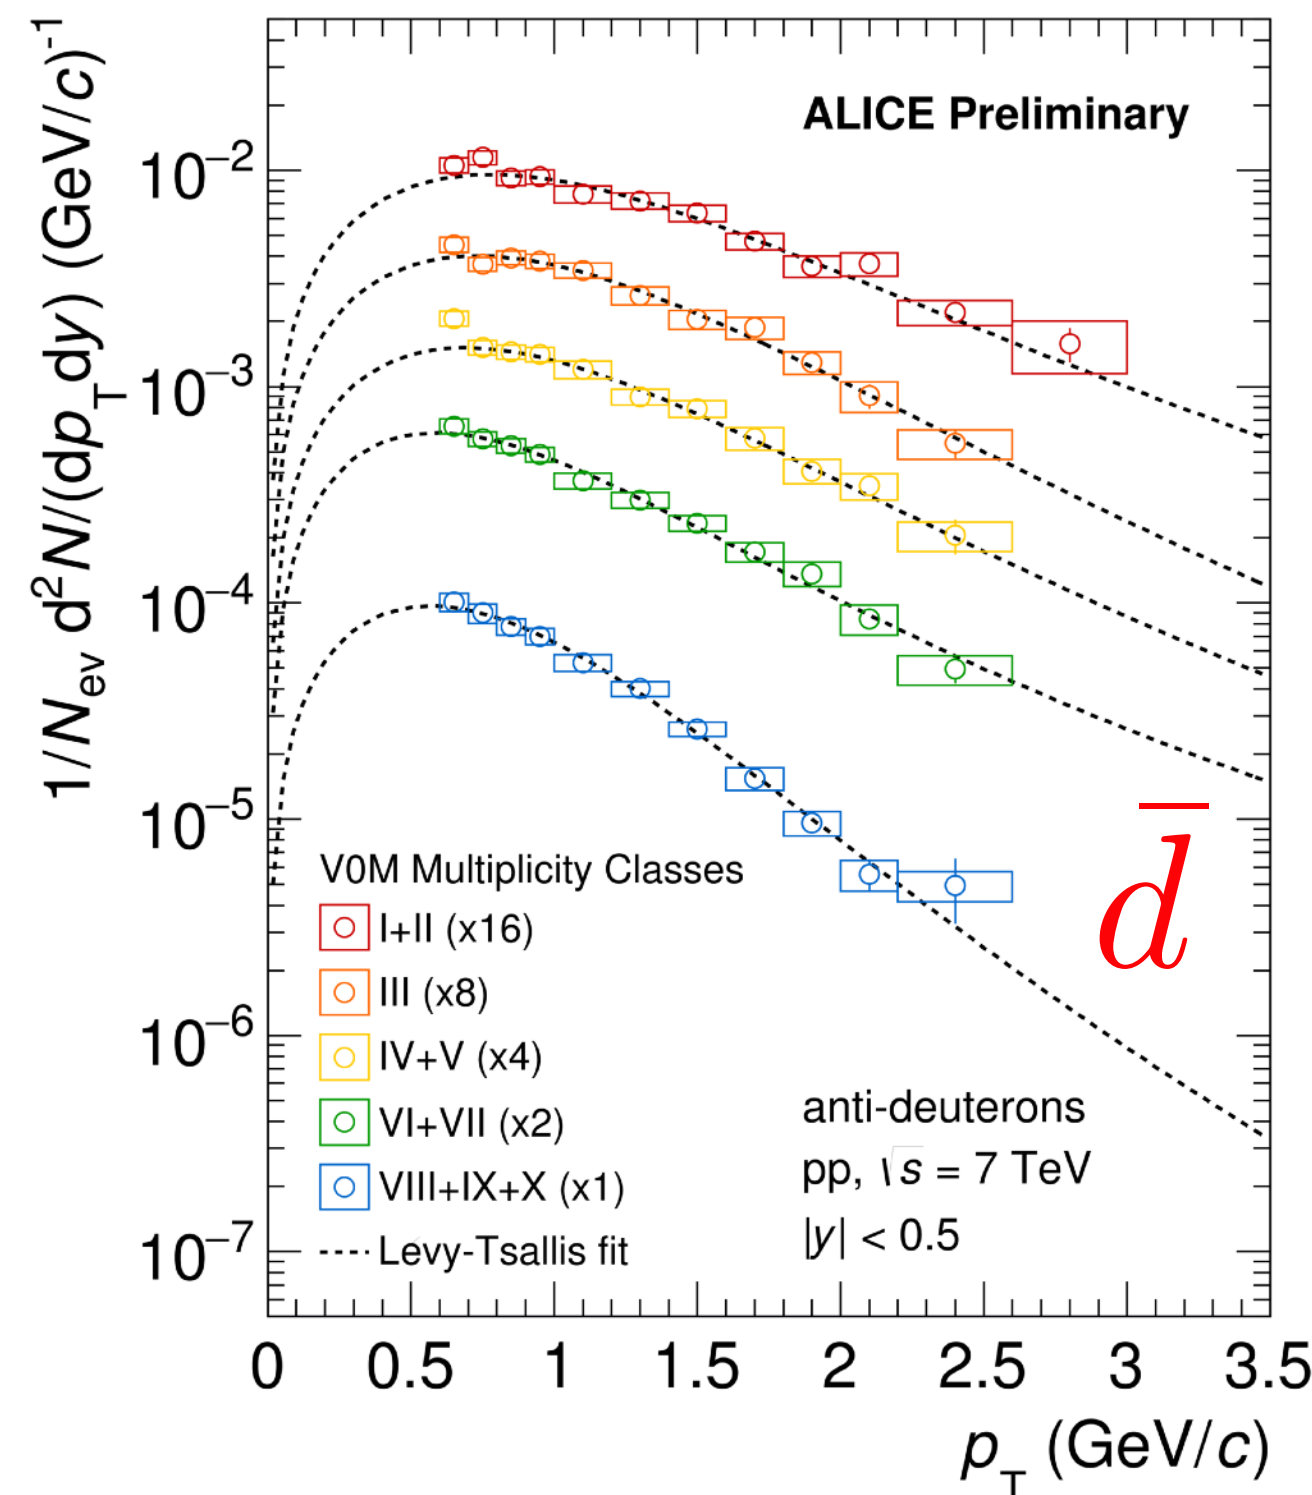

Andronic, P. Braun-Munzinger, J. Stachel, H. Stocker. - *Phys. Lett. B* 697, 203 (2011)

	Yield/event at mid-rapidity and central collisions
$\pi$	$\sim 800$
$p$	$\sim 40$
$\Lambda$	$\sim 30$
$d$	$\sim 0.17$
${}^3\text{He}$	$\sim 0.01$
${}^3_{\Lambda}\text{H}$	$\sim 0.003$

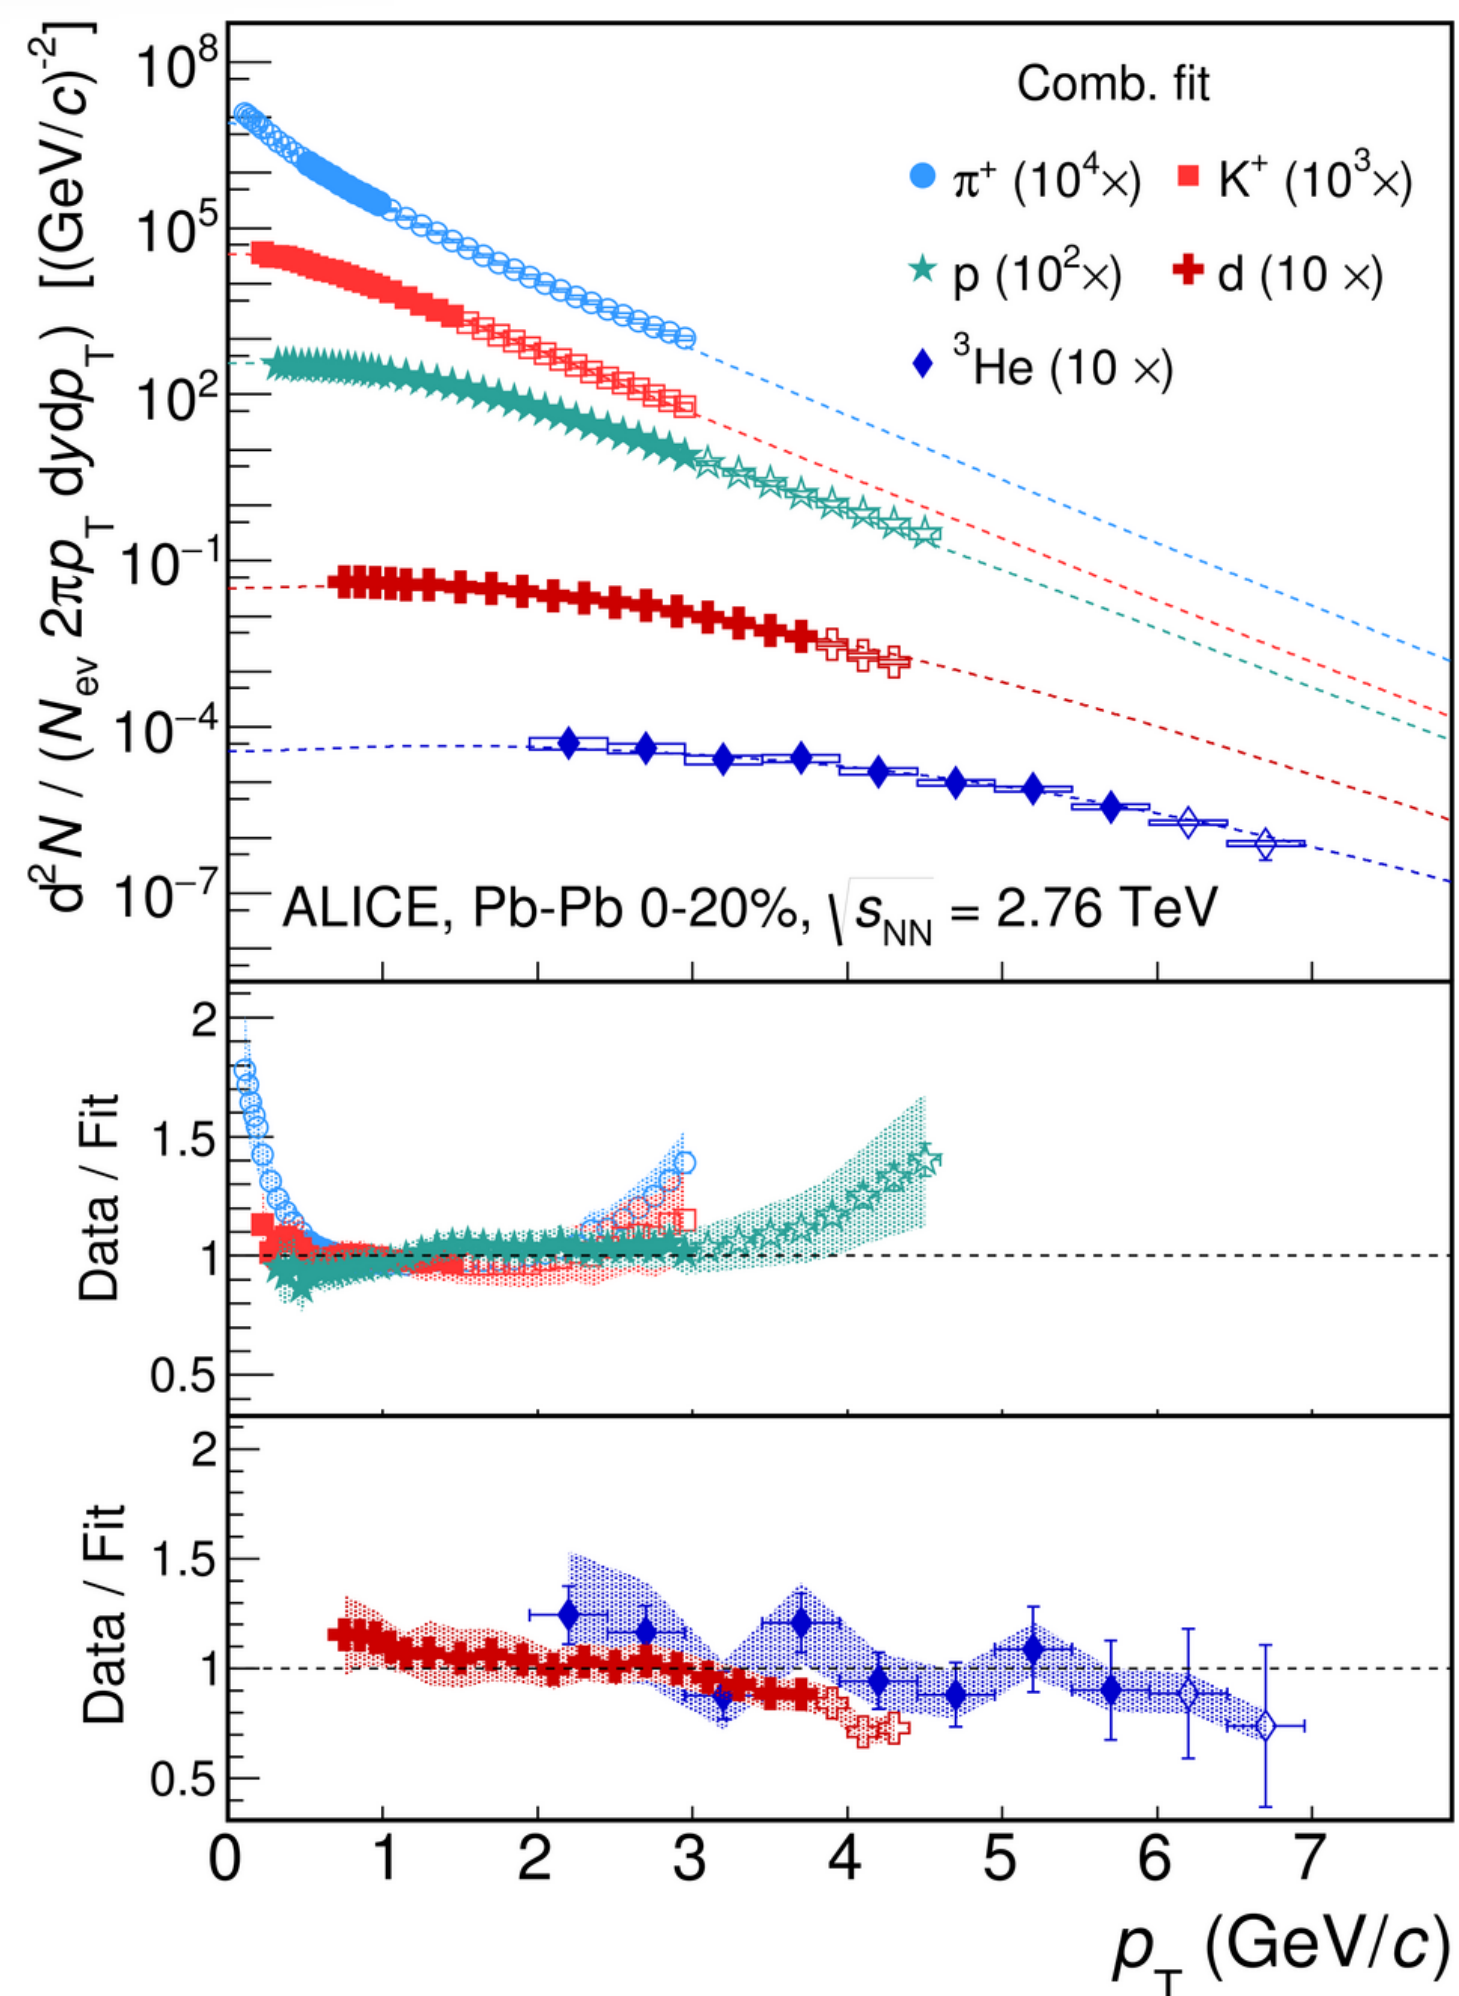

A. Andronic et al., *Phys. Lett. B* 697, 203 (2011)

New results from LHC- Run2 at 7 TeV and 13 TeV vs multiplicity and first ever observation of anti- $^3\text{He}$  in pp collisions from LHC-Run1 data

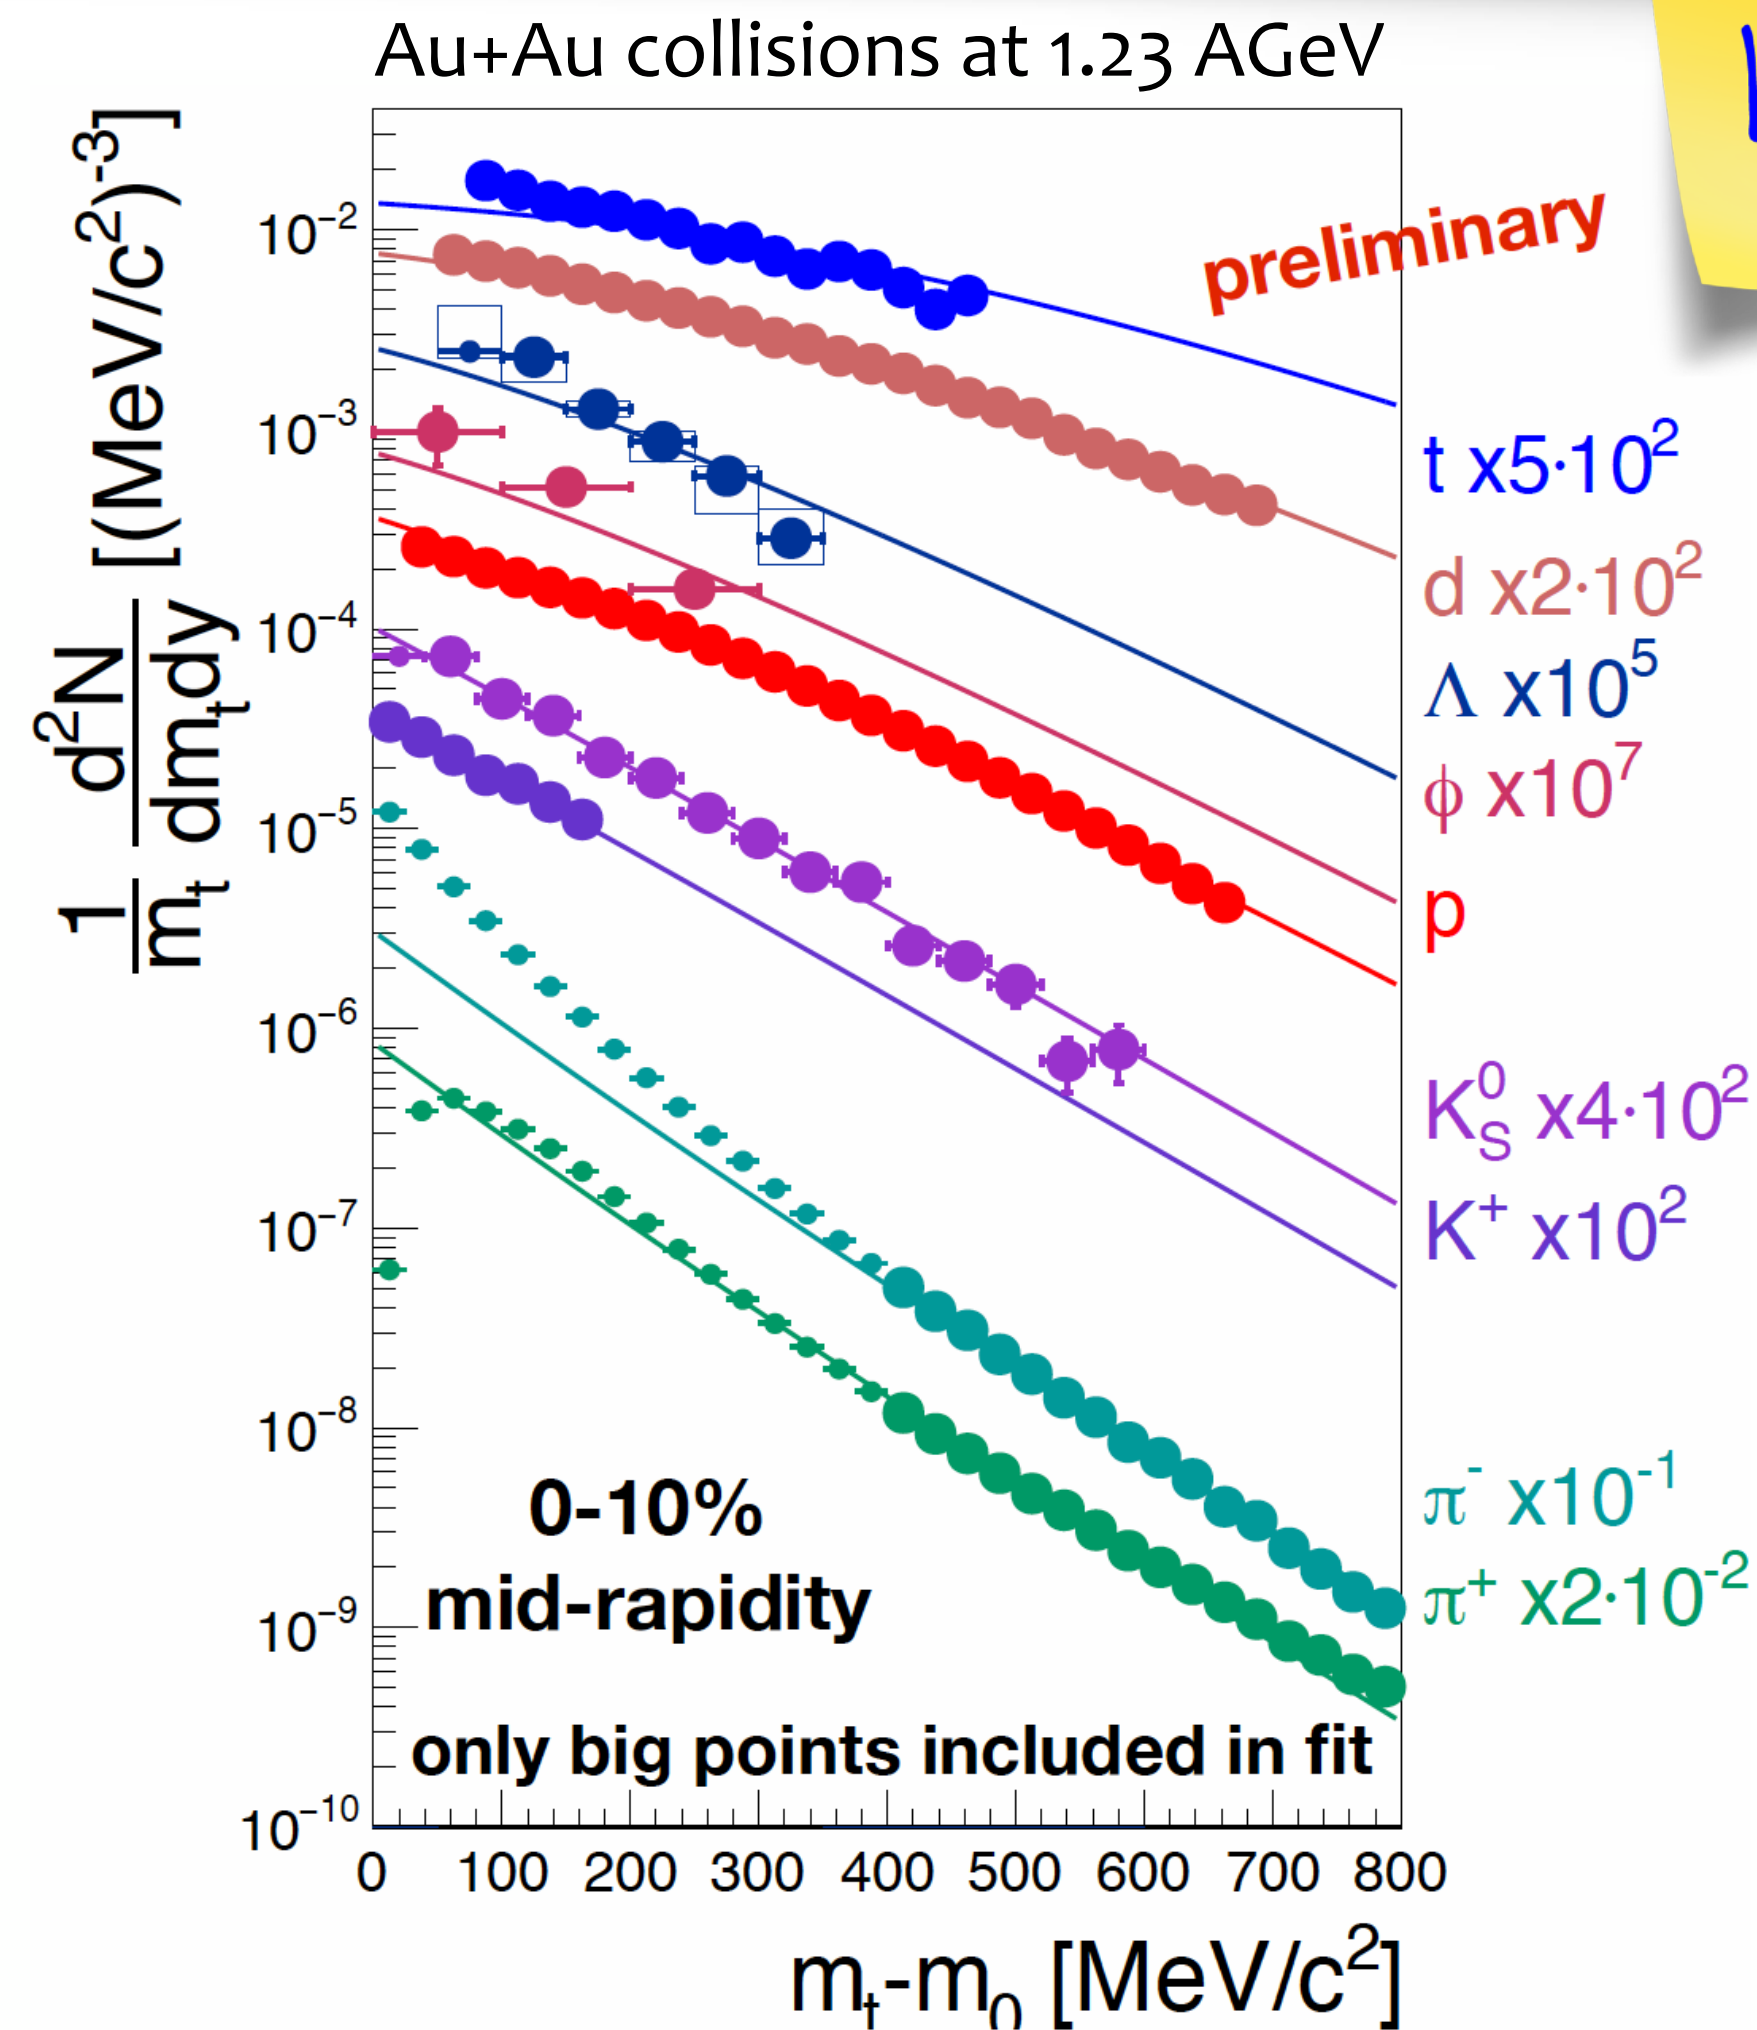

- pp spectrum shows no sign of radial flow (spectra hardening is clearly seen in heavy-ion collisions)
  - integrated yields reduced of a factor  $\sim 1000$  when adding a nucleon
- ➡ it is  $\sim 300$  and  $\sim 600$  in Pb-Pb and p-Pb collisions, respectively

# Nuclei production in heavy ion collisions

The hardening of the spectra at the LHC for central collisions is qualitatively well described by the combined BW

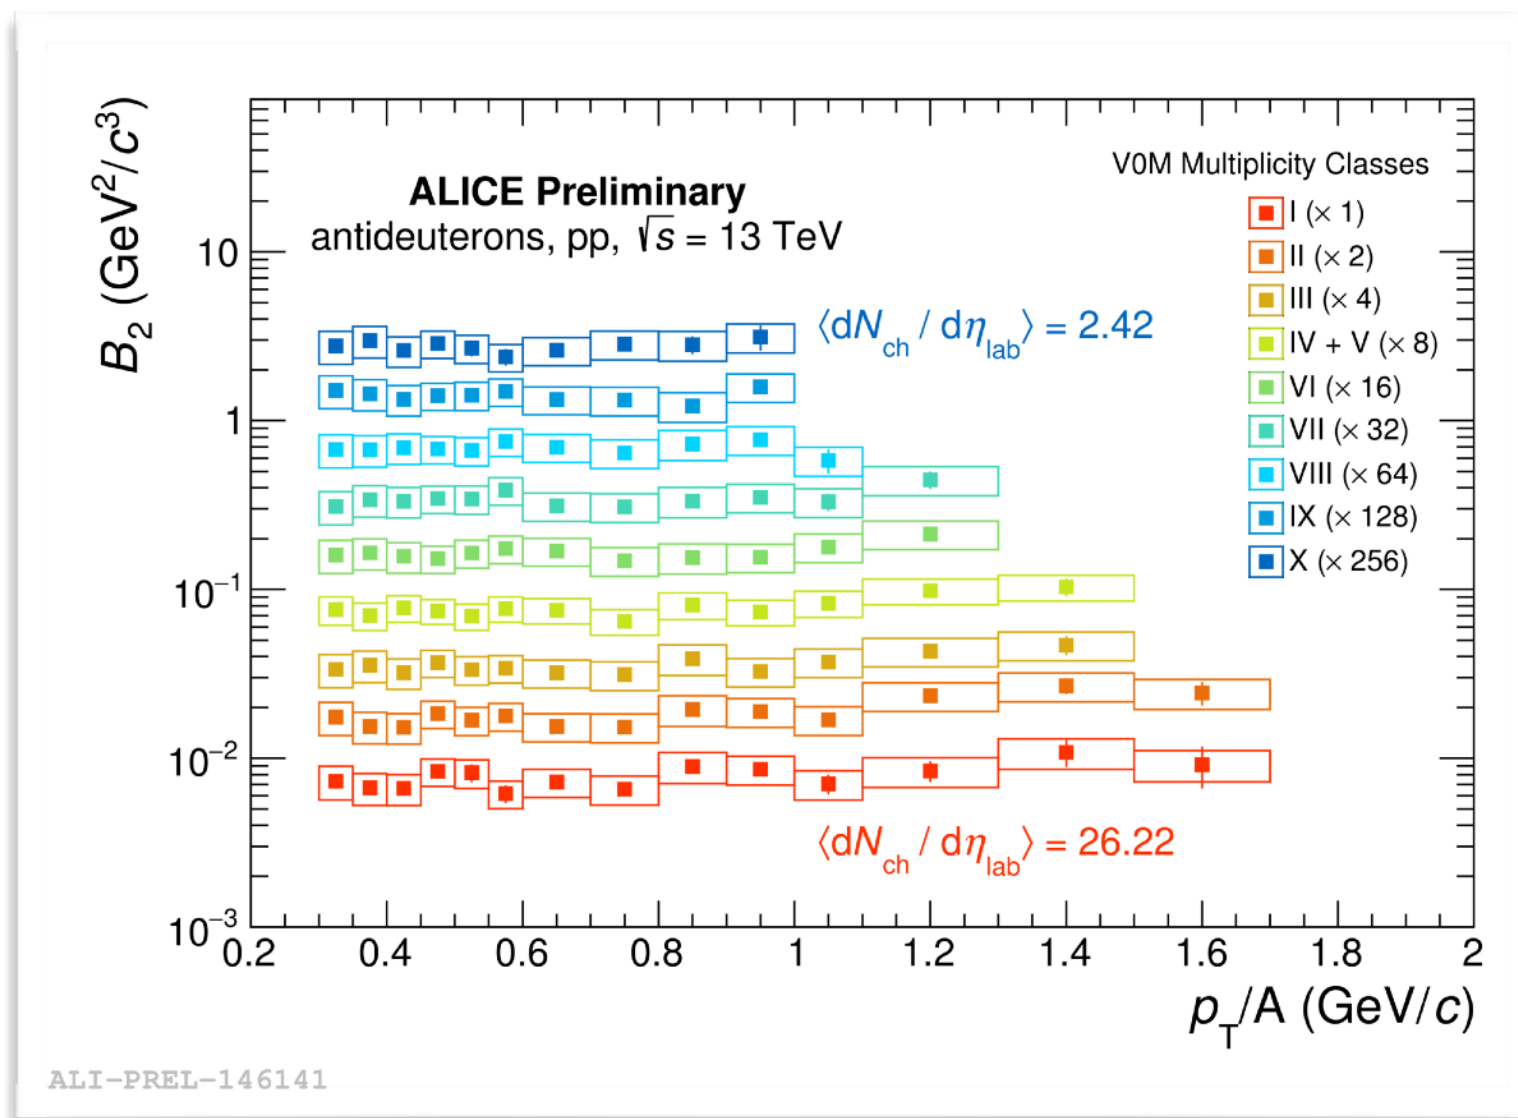

Reasonable description of protons, light nuclei, kaons and pions (at higher  $m_t$ )

Latest news

The formation probability of composite nuclei can be quantified through the coalescence parameter  $B_A$

$$B_A = \frac{E_A \frac{d^3 N_A}{dp_A^3}}{\left( E_p \frac{d^3 N_p}{dp_p^3} \right)^A}$$

- No  $p_T$  dependence as suggested by simple coalescence models

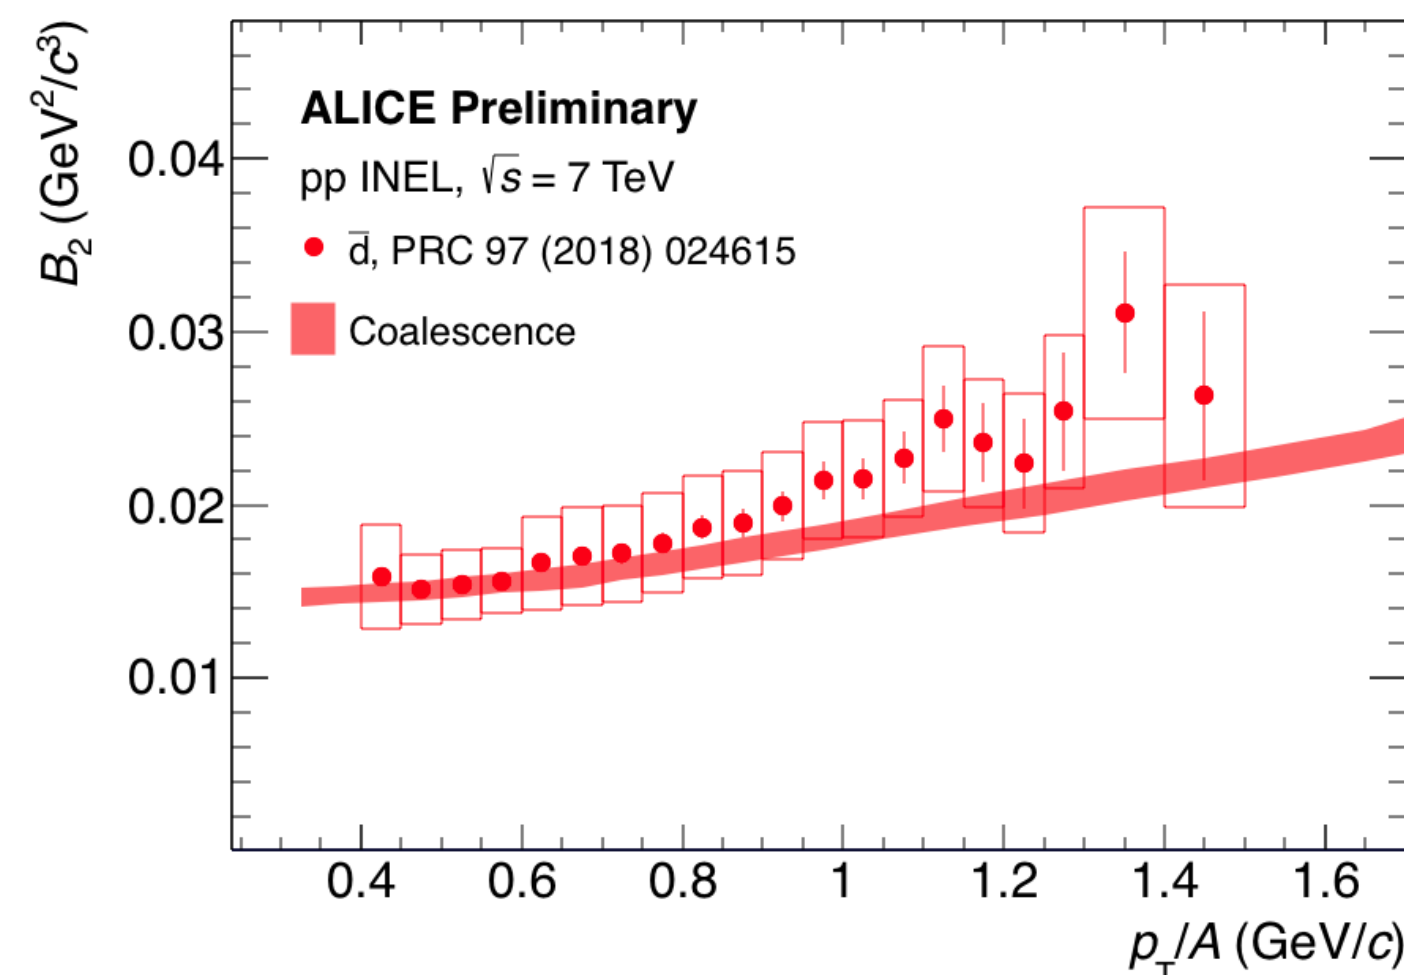

# Coalescence parameters in small systems at the LHC

Latest news

The formation probability of composite nuclei can be quantified through the coalescence parameter  $B_A$

$$B_A = \frac{E_A \frac{d^3 N_A}{dp_A^3}}{\left( E_p \frac{d^3 N_p}{dp_p^3} \right)^A}$$

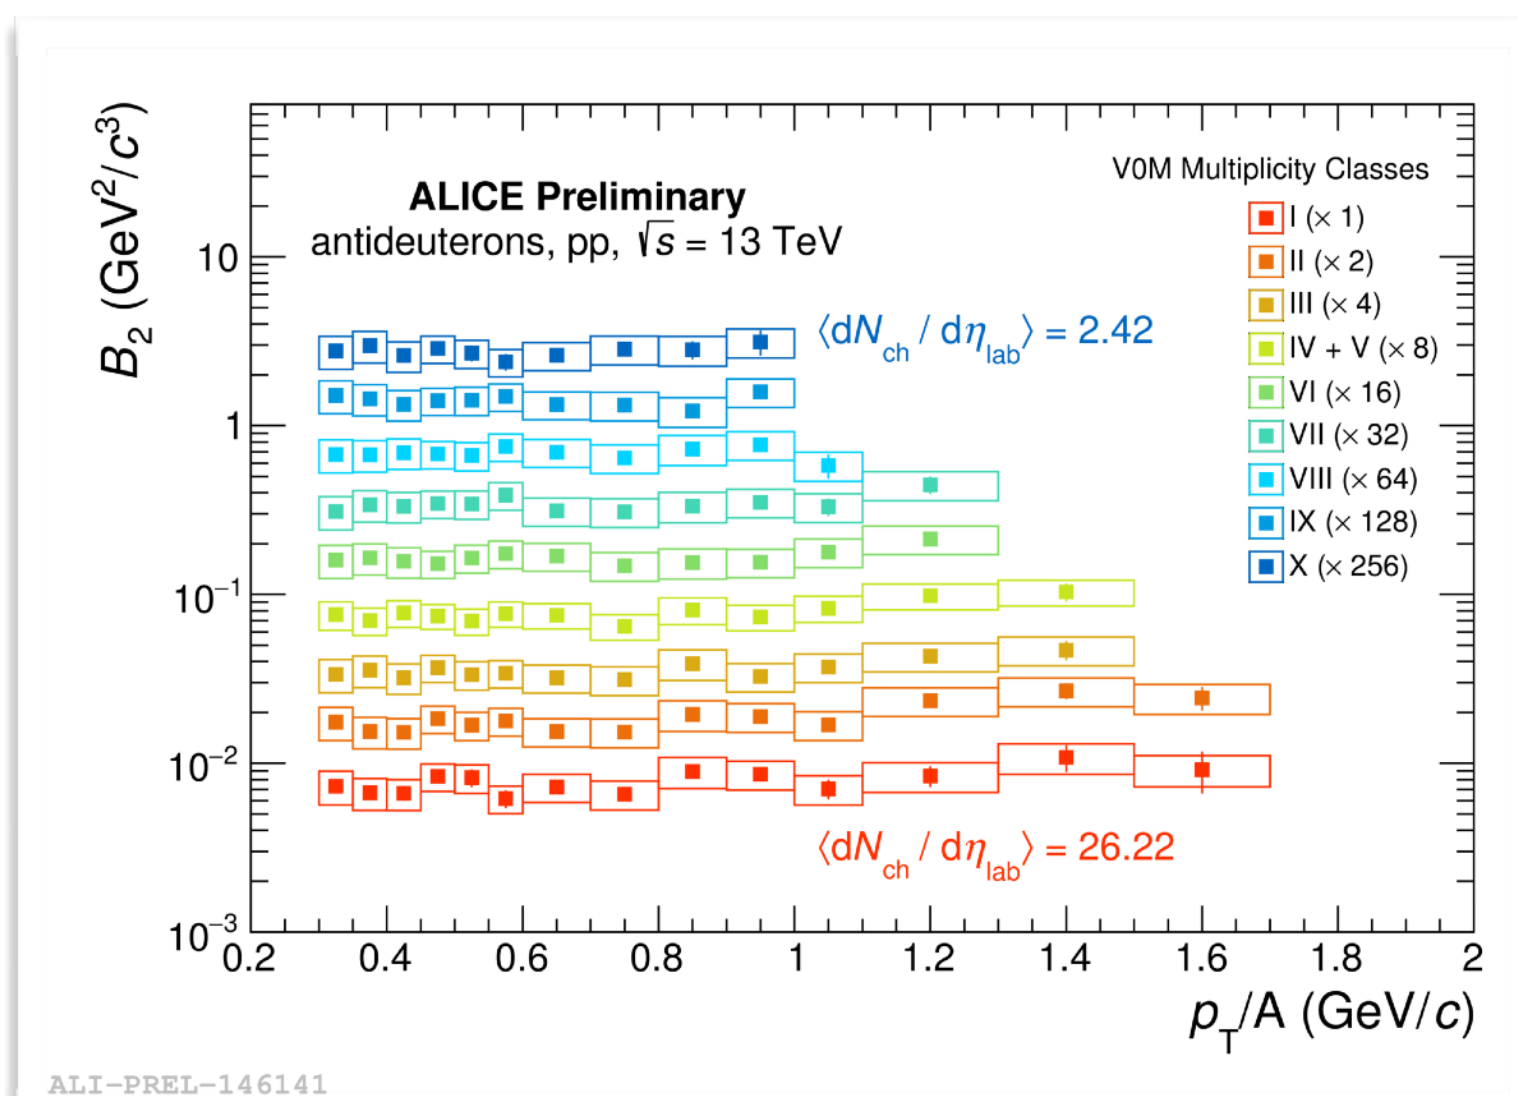

what about the multiplicity integrated  $B_2$  trend?

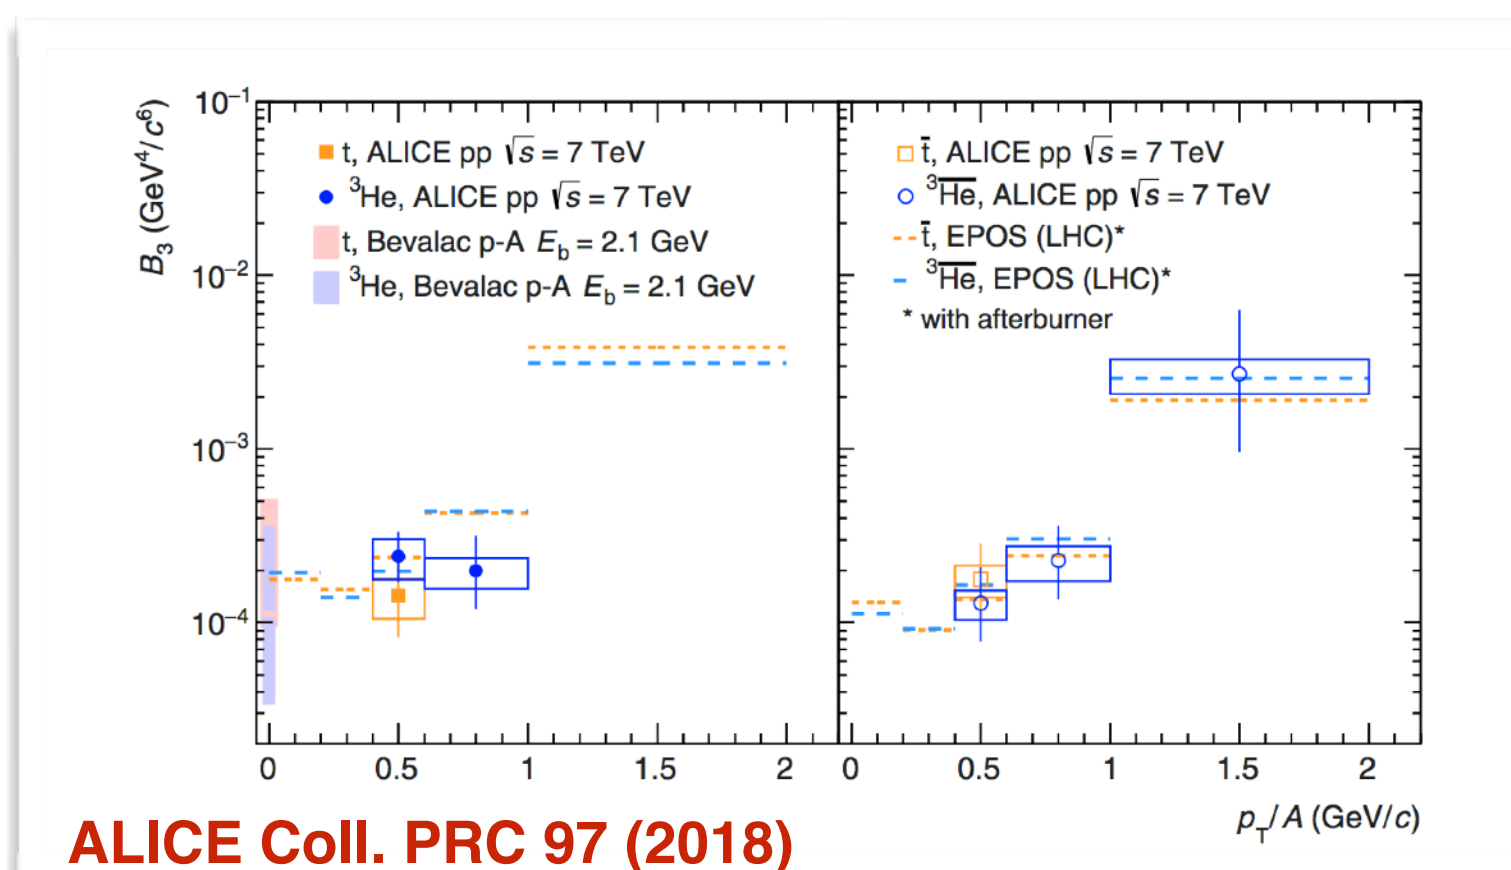

Simple Coalescence reproduces the experimental trend

→ evolution of the primary proton spectra across multiplicity can also explain the result

→ no need to introduce hard scattering effects

- No  $p_T$  dependence as suggested by simple coalescence models

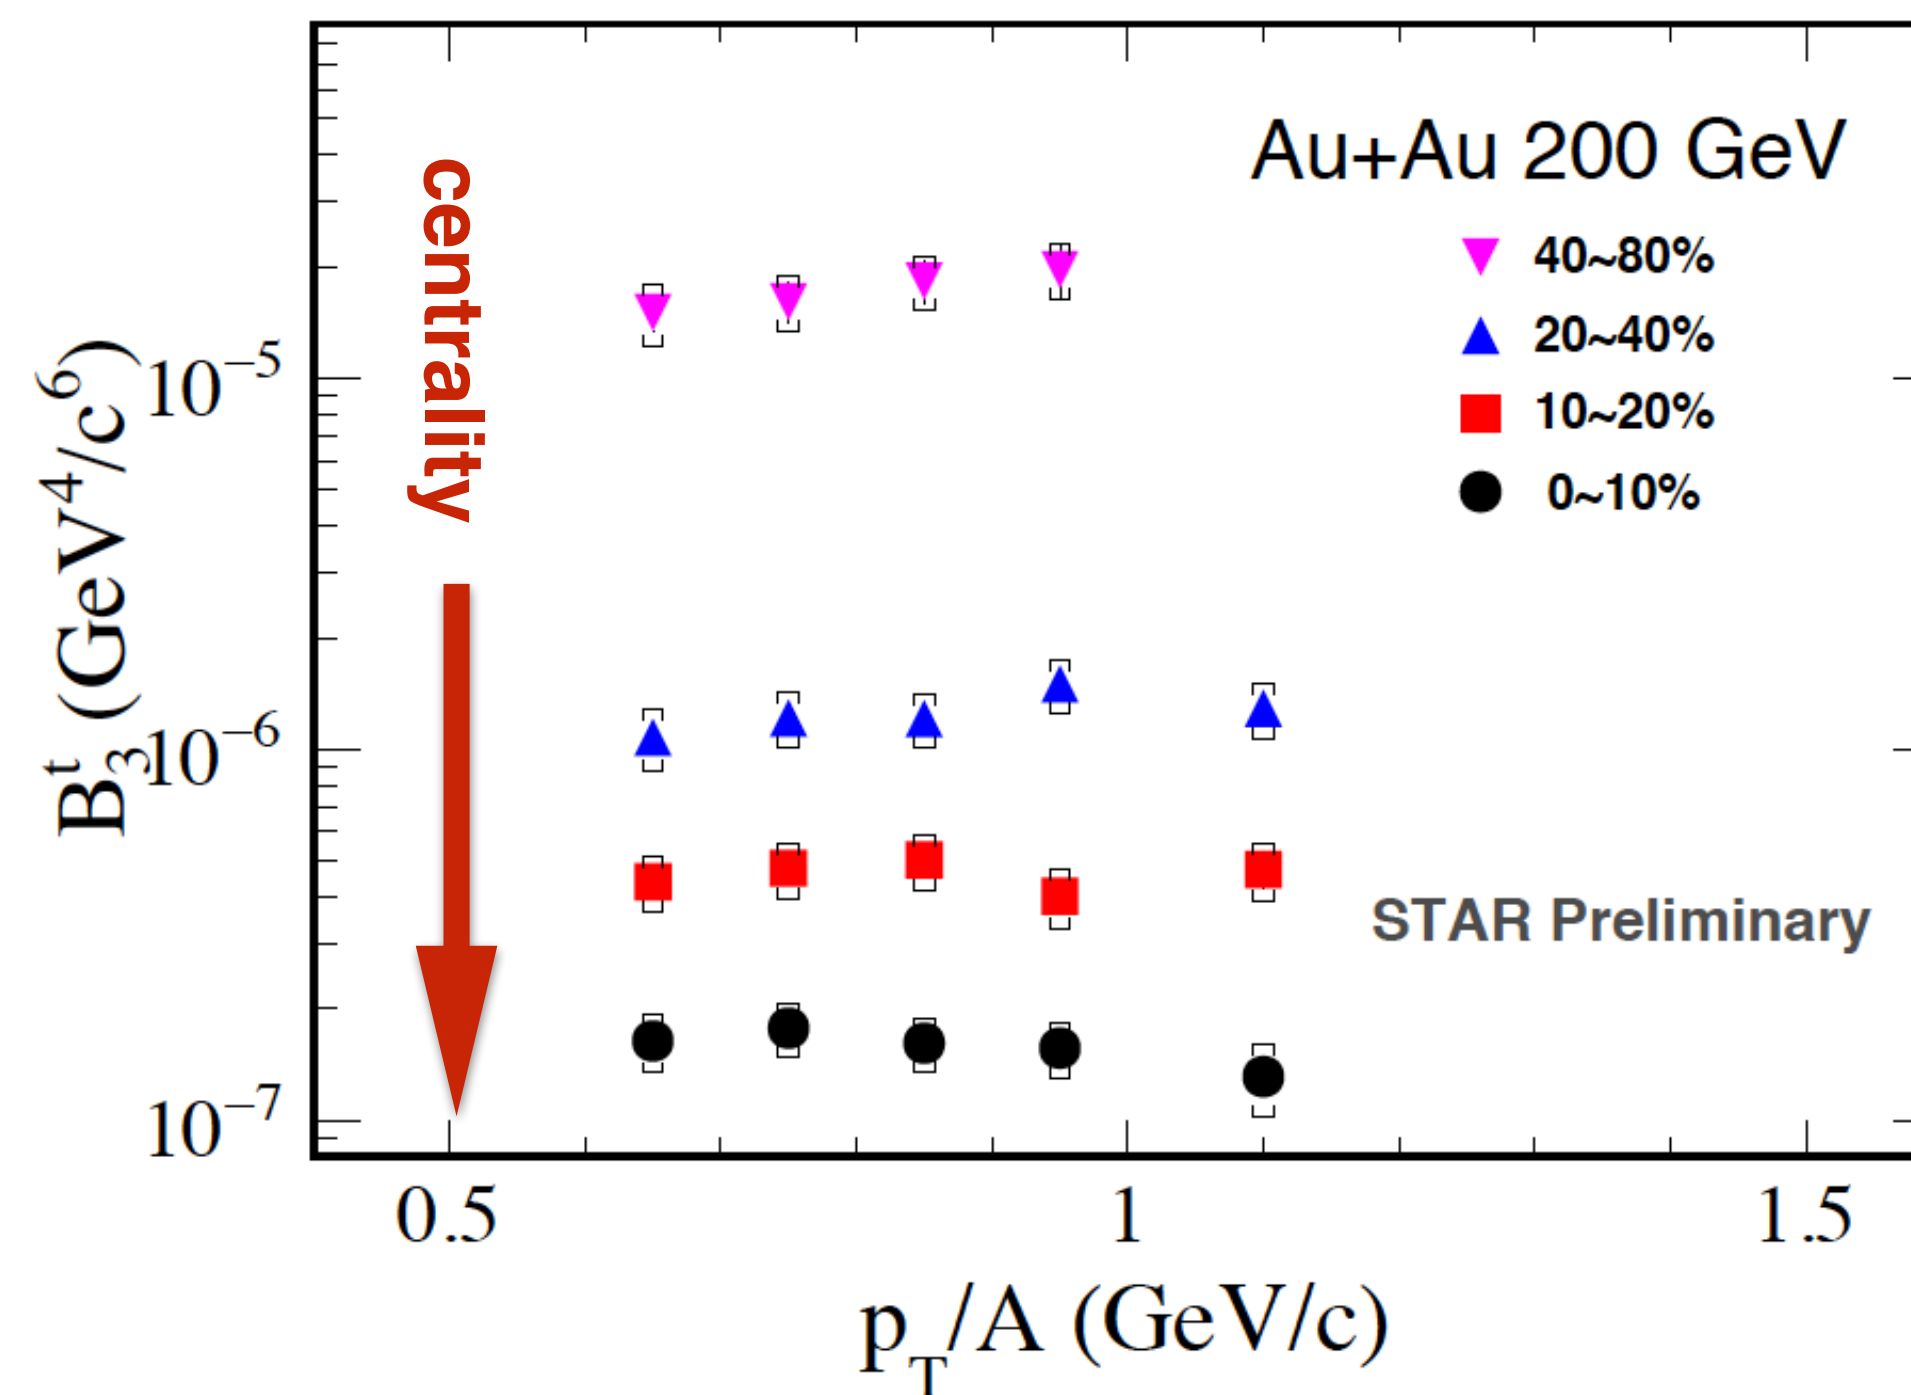

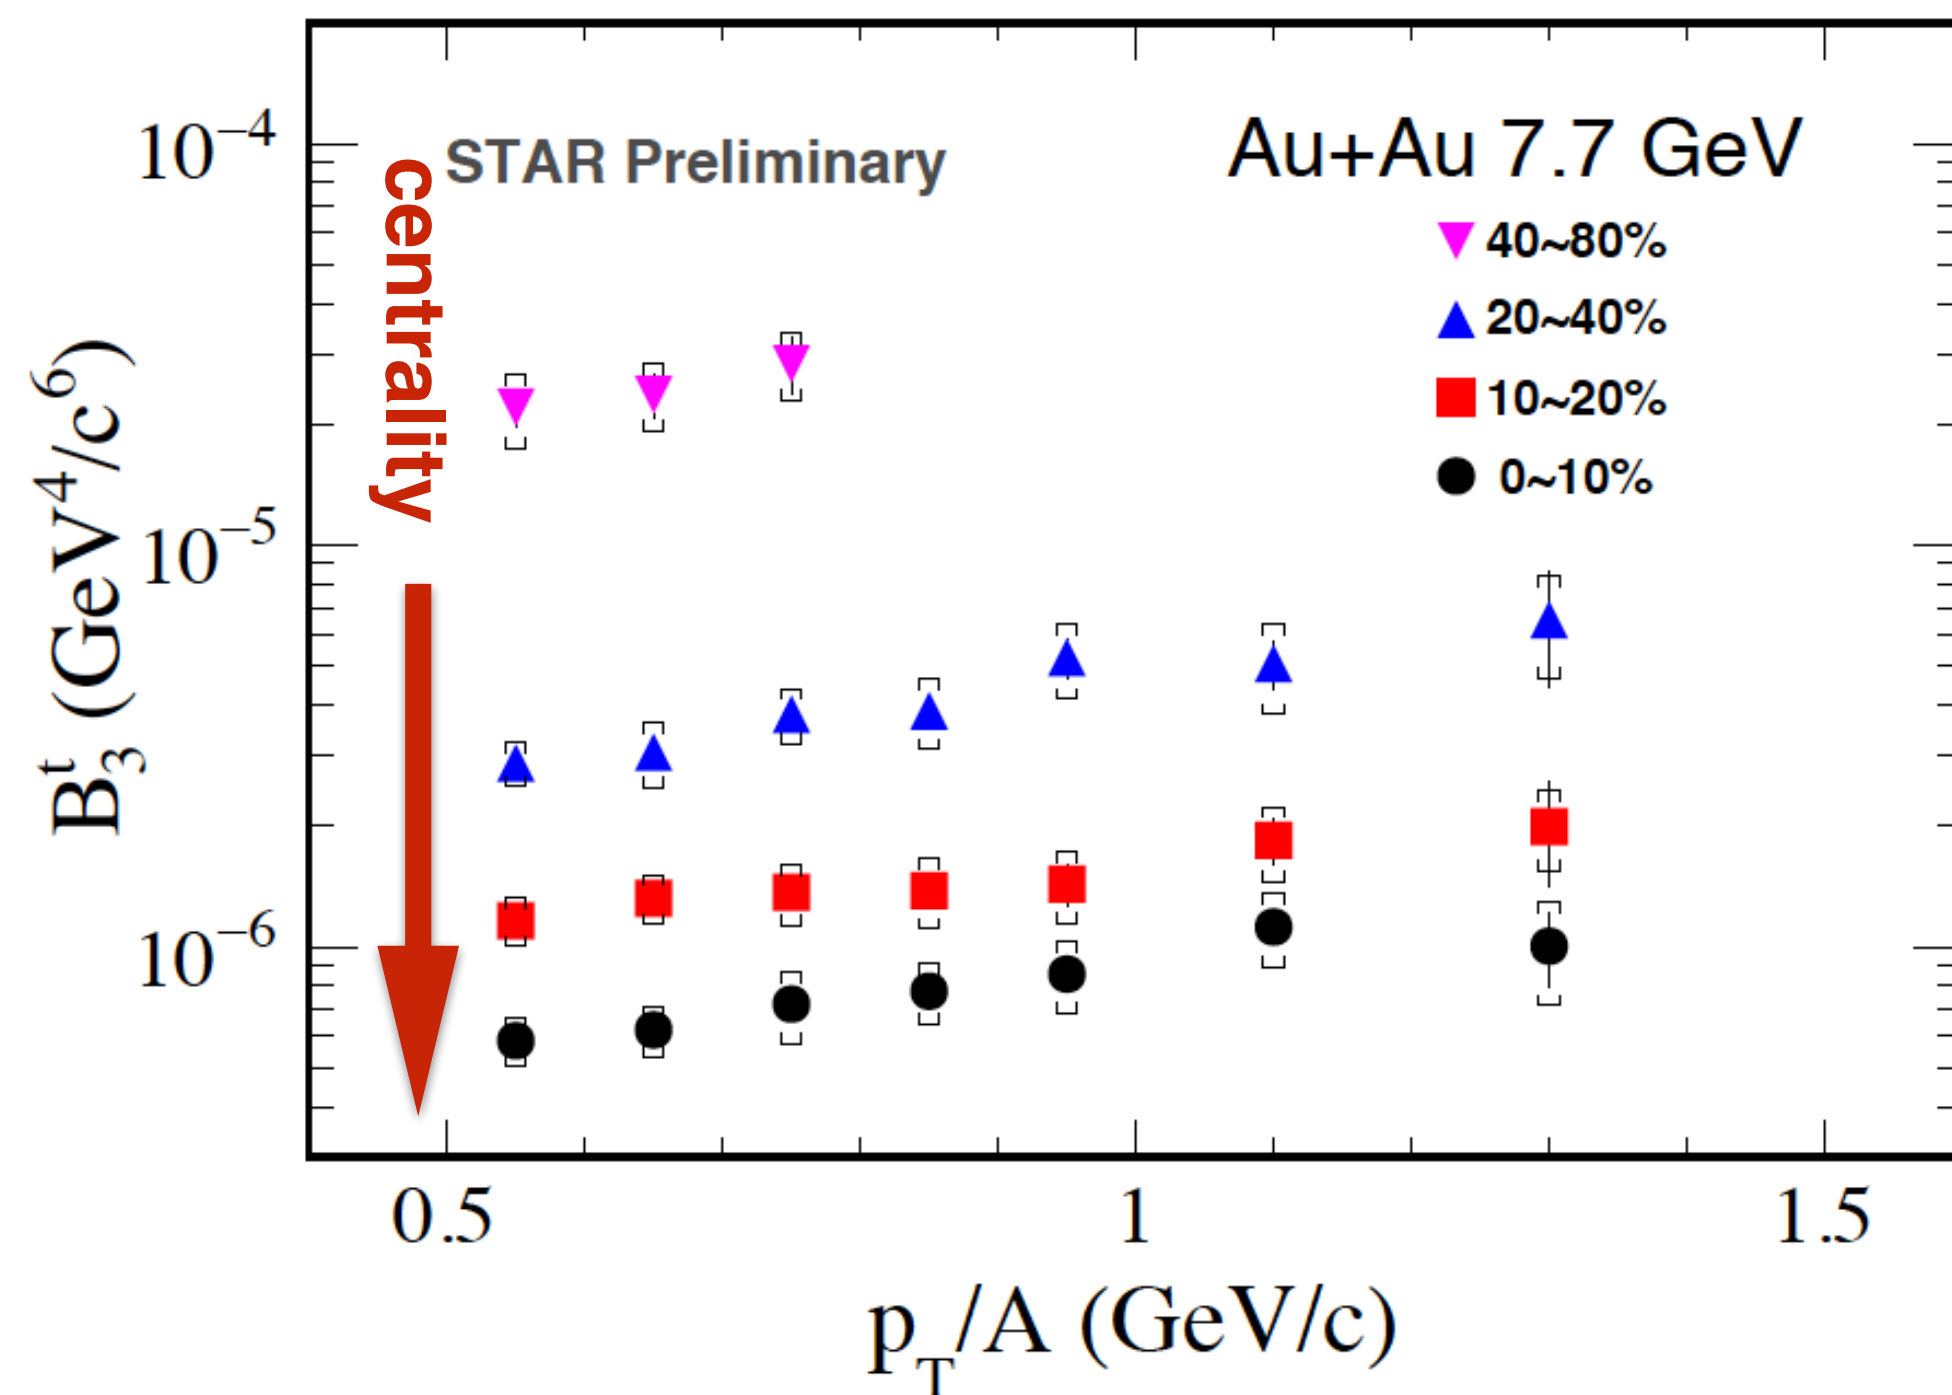

..and what about  $B_3$  ?

First ever measurement in high energy physics

- reproduced with QCD-inspired event generators with a coalescence-based afterburner
- low  $p_T$  values compatible with those obtained in p-C, p-Cu, and p-Pb collisions at Bevalac [Phys. Rev. C 24, 971]

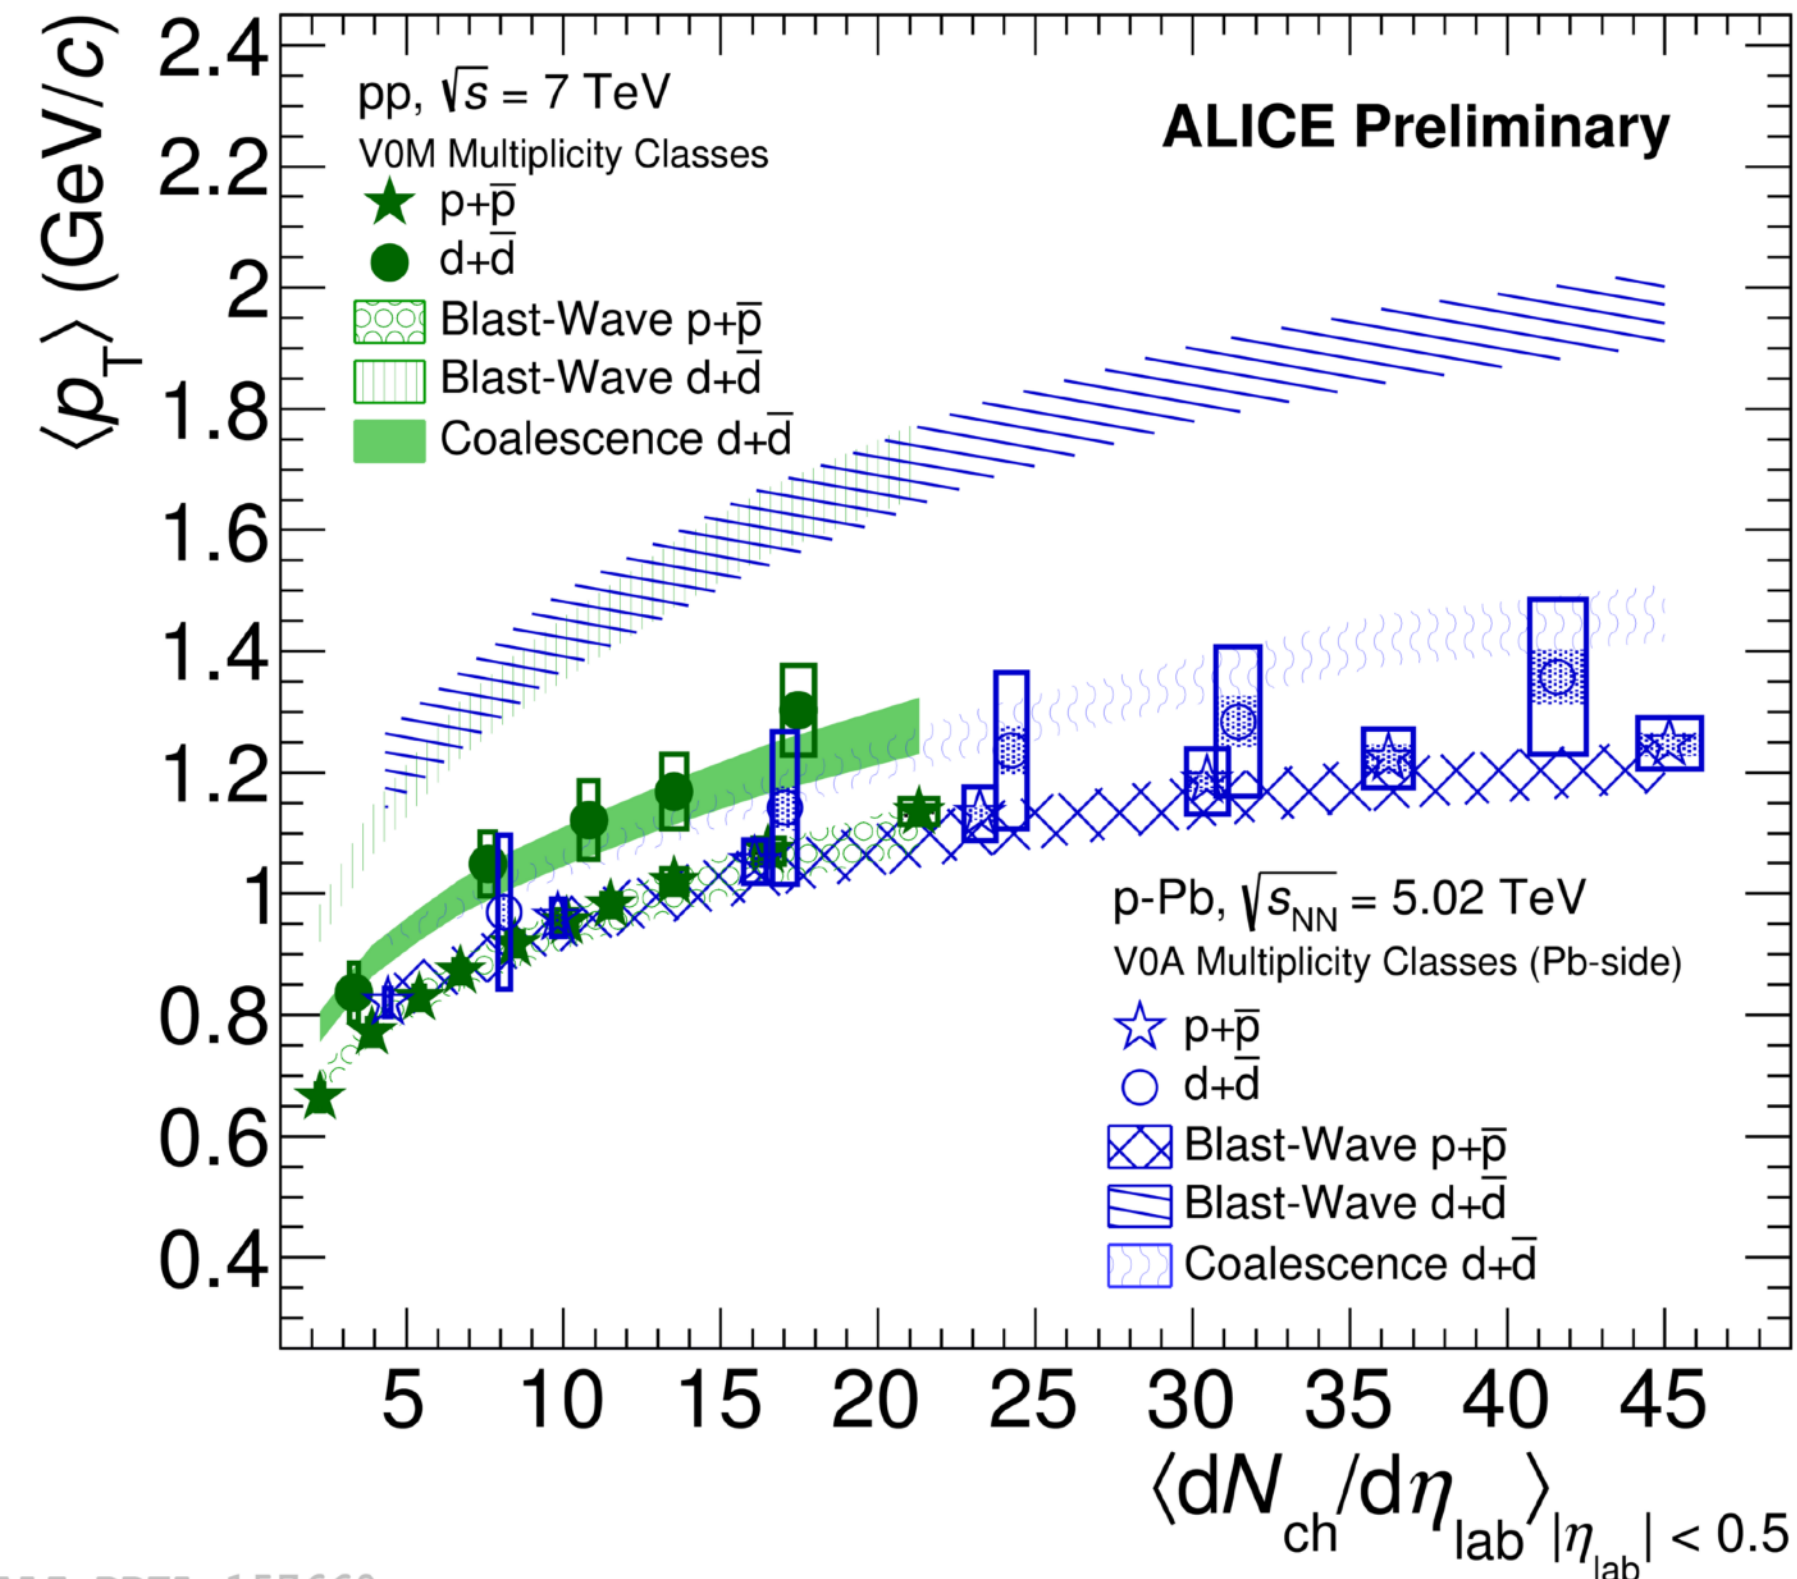

# Coalescence parameters for tritons at RHIC

Latest news

- $B_3$  of tritons decreases from peripheral to central collisions and when beam energy increase
- It would be important to extend the  $p_T$  reach to have a better feeling about the  $p_T$  dependence

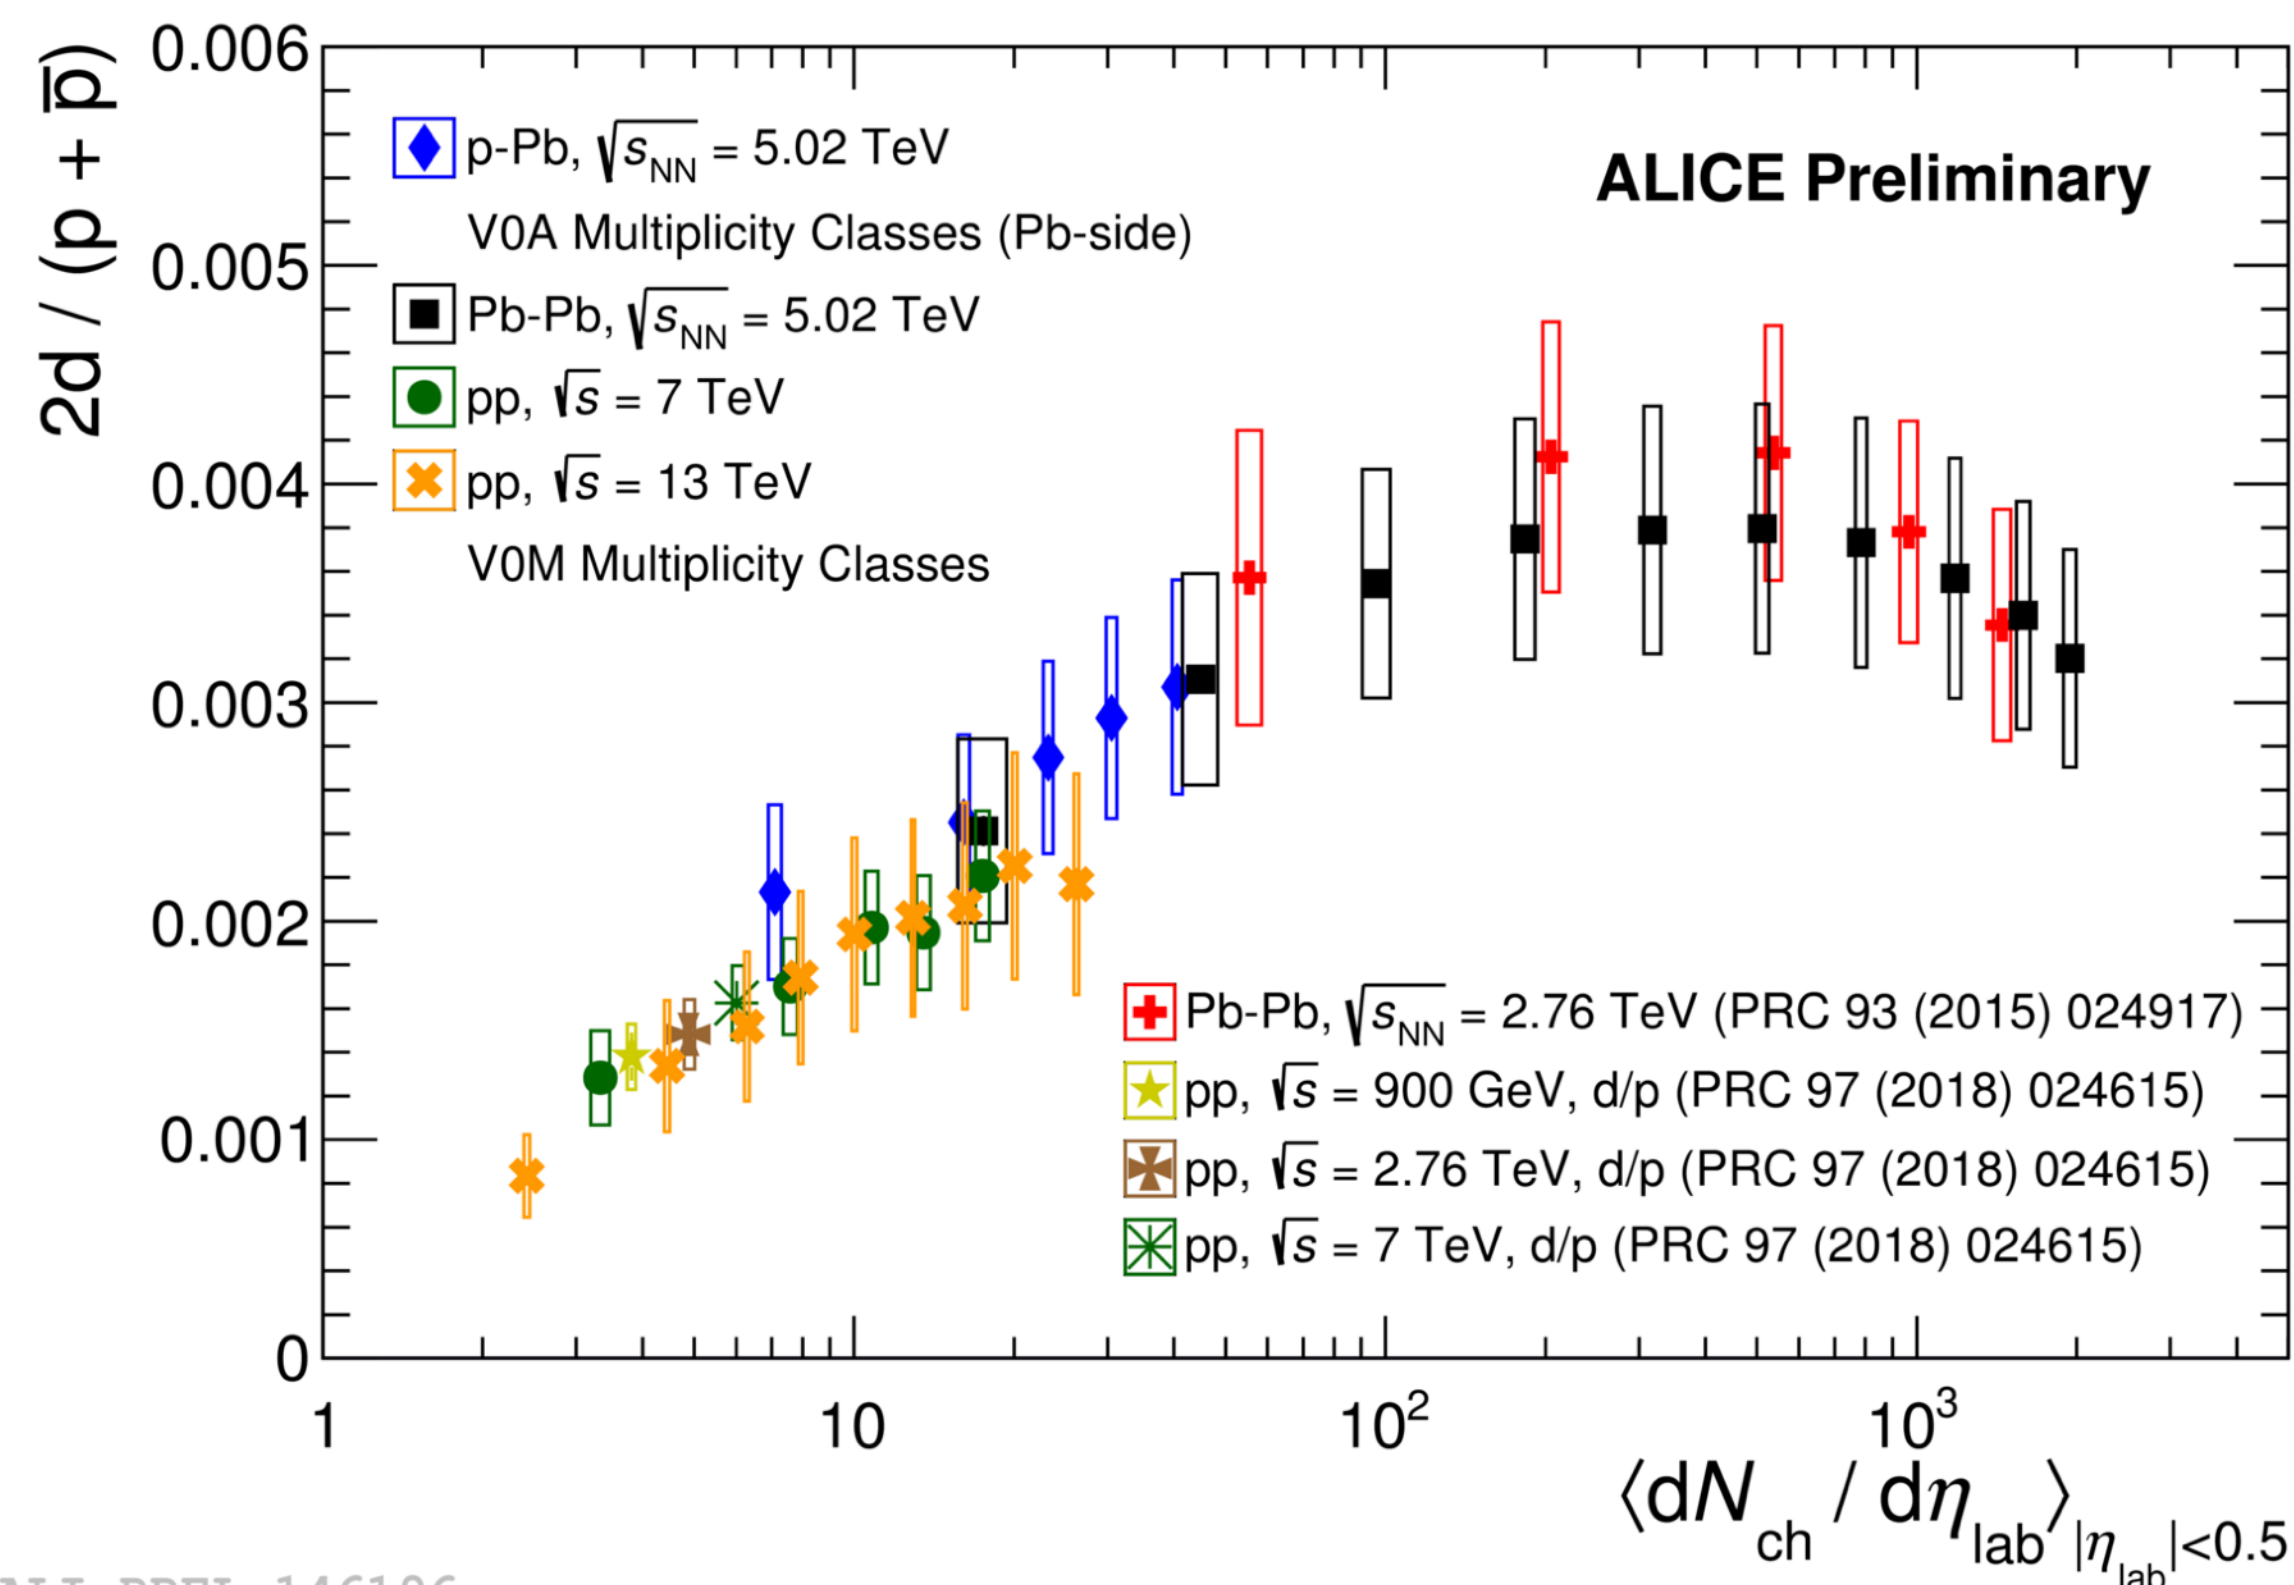

**Triton measurement: quite challenging measurement at the LHC**

- production in **pp** and **p-Pb**: fully inspired-hydrodynamic approach (Blast-Wave<sup>1</sup>) does not describe simultaneously nuclei and protons
- assumption of a **radially expanding thermalized source not satisfactory** in small systems
- coalescence model reproduce the results in small systems

# What have we understood?

Latest news

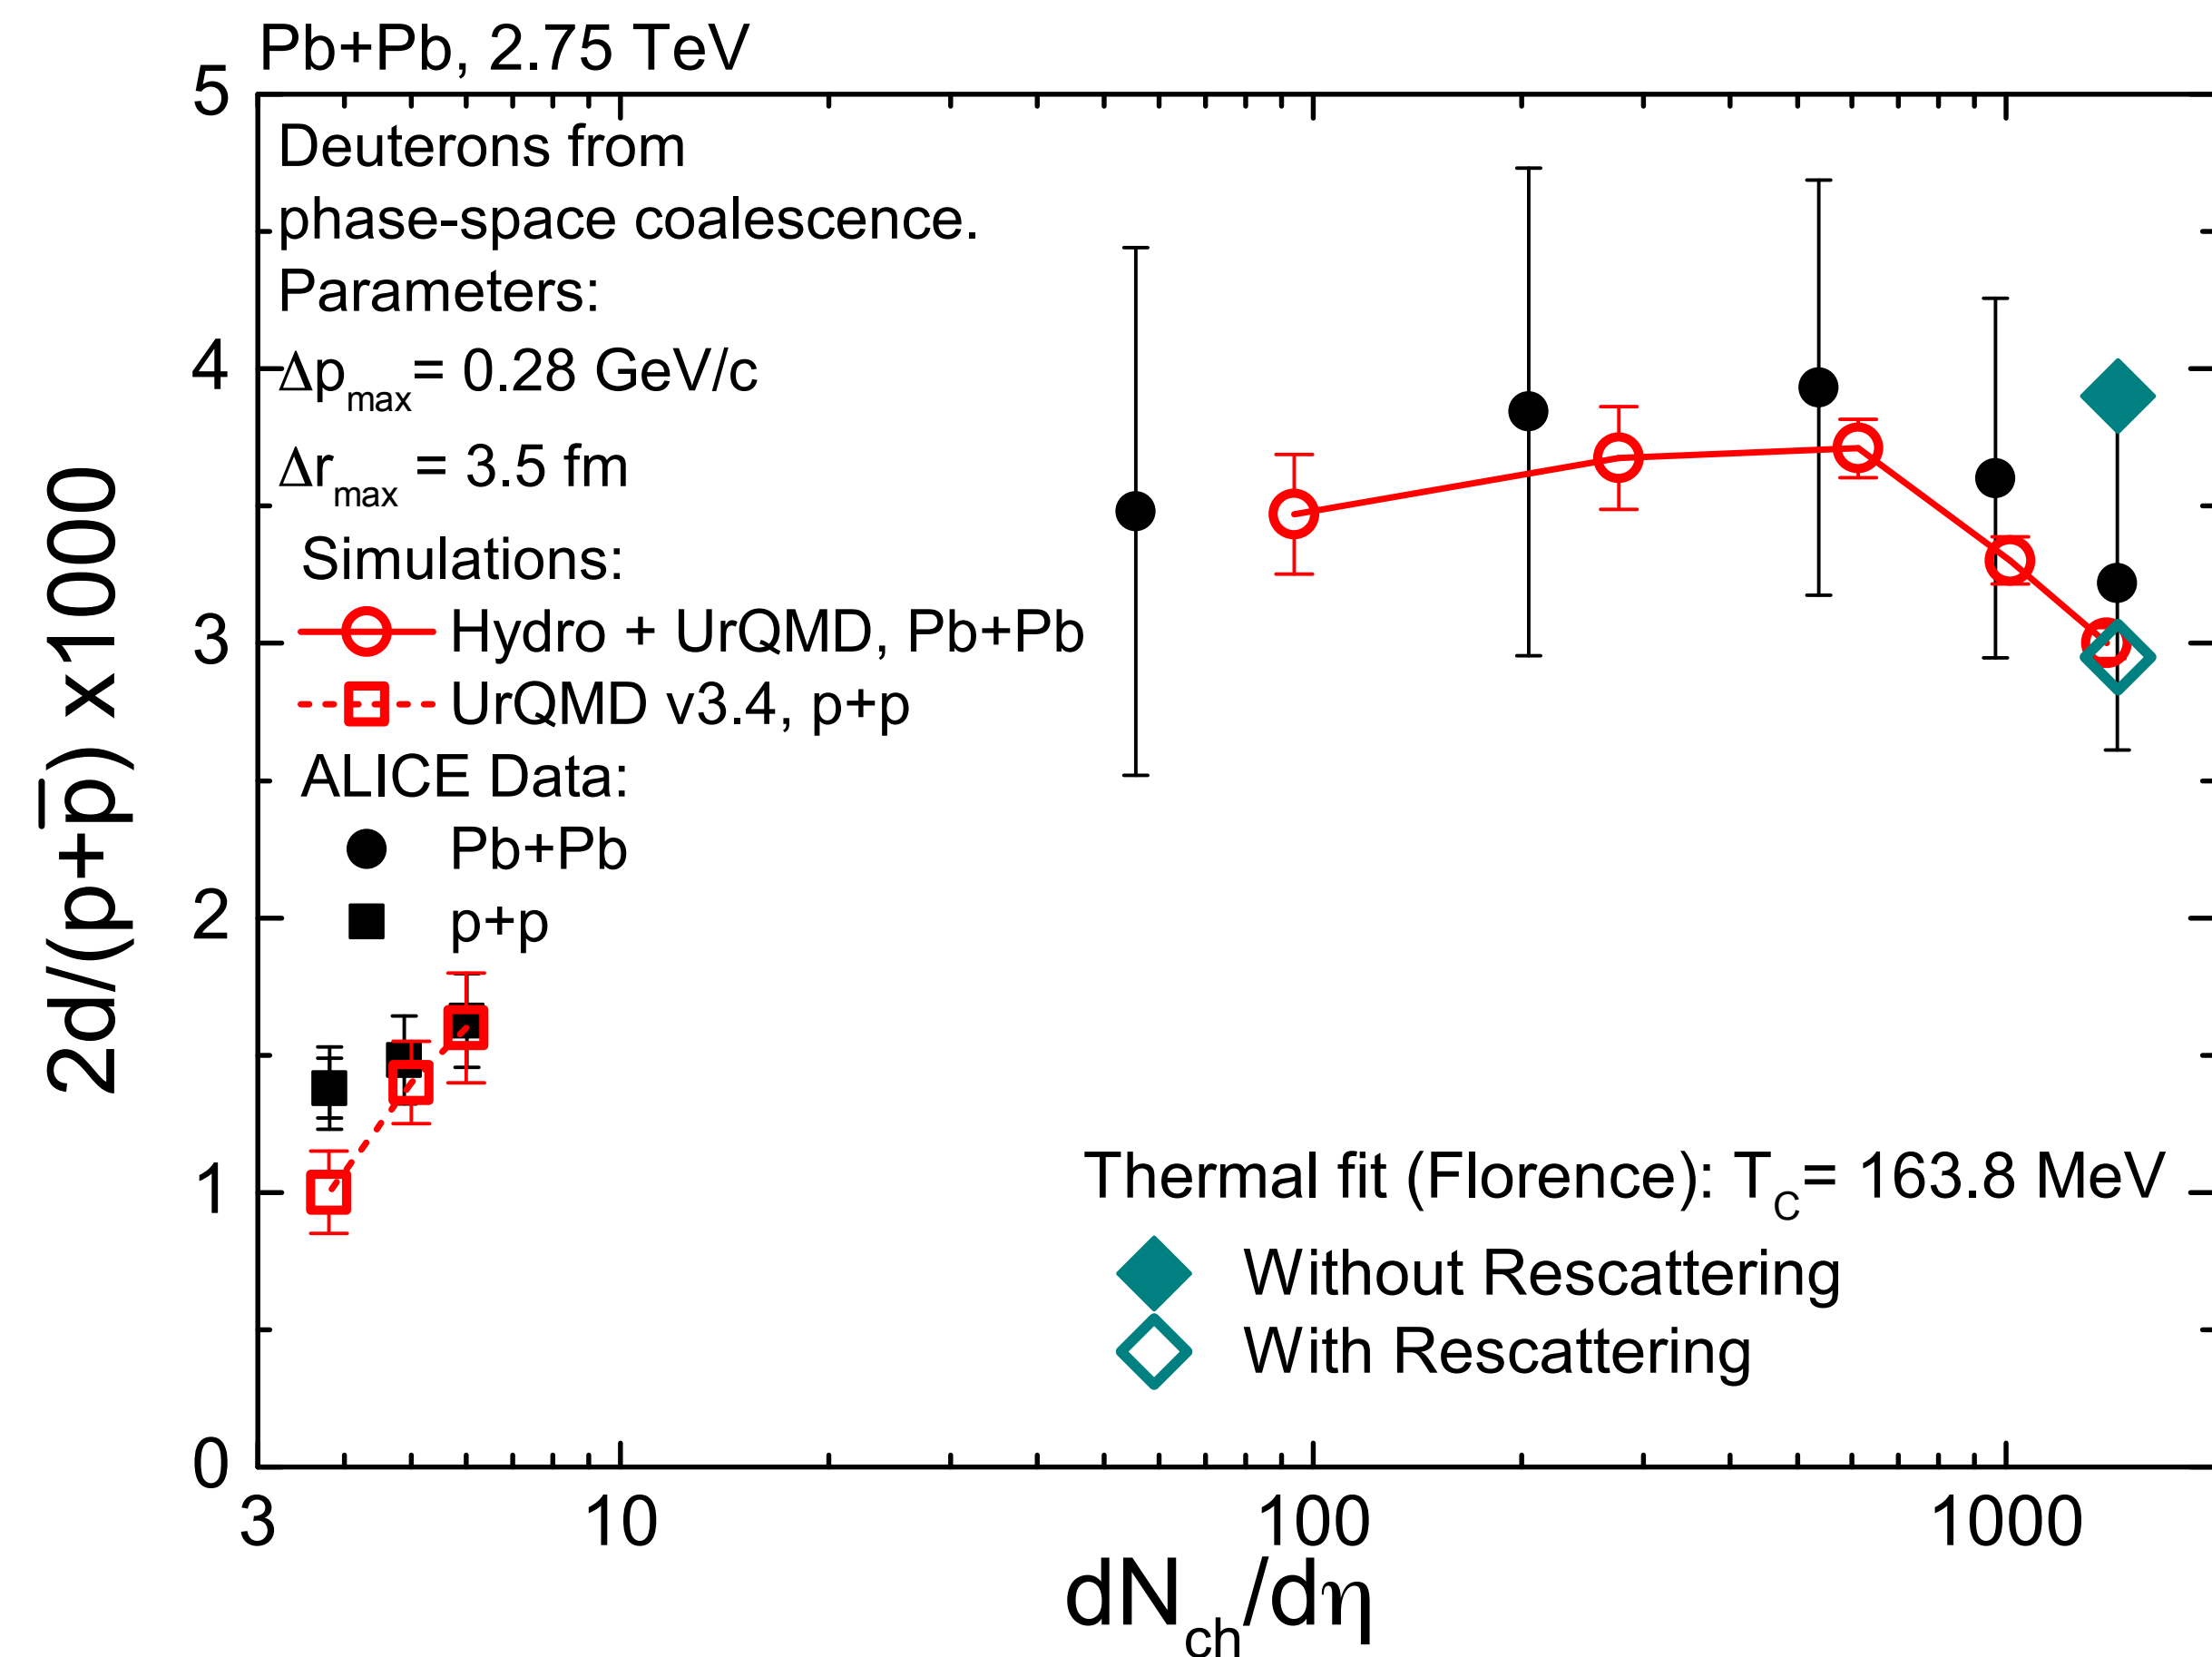

ALI-PREL-146196

- Latest results in pp at **7 TeV** and **13 TeV** fit the trend drawn by other energies/colliding systems at the LHC
- matching of pp and p-Pb points at similar multiplicities
- **rising** with multiplicity explained in coalescence models as due to an **increased proton and neutron density**

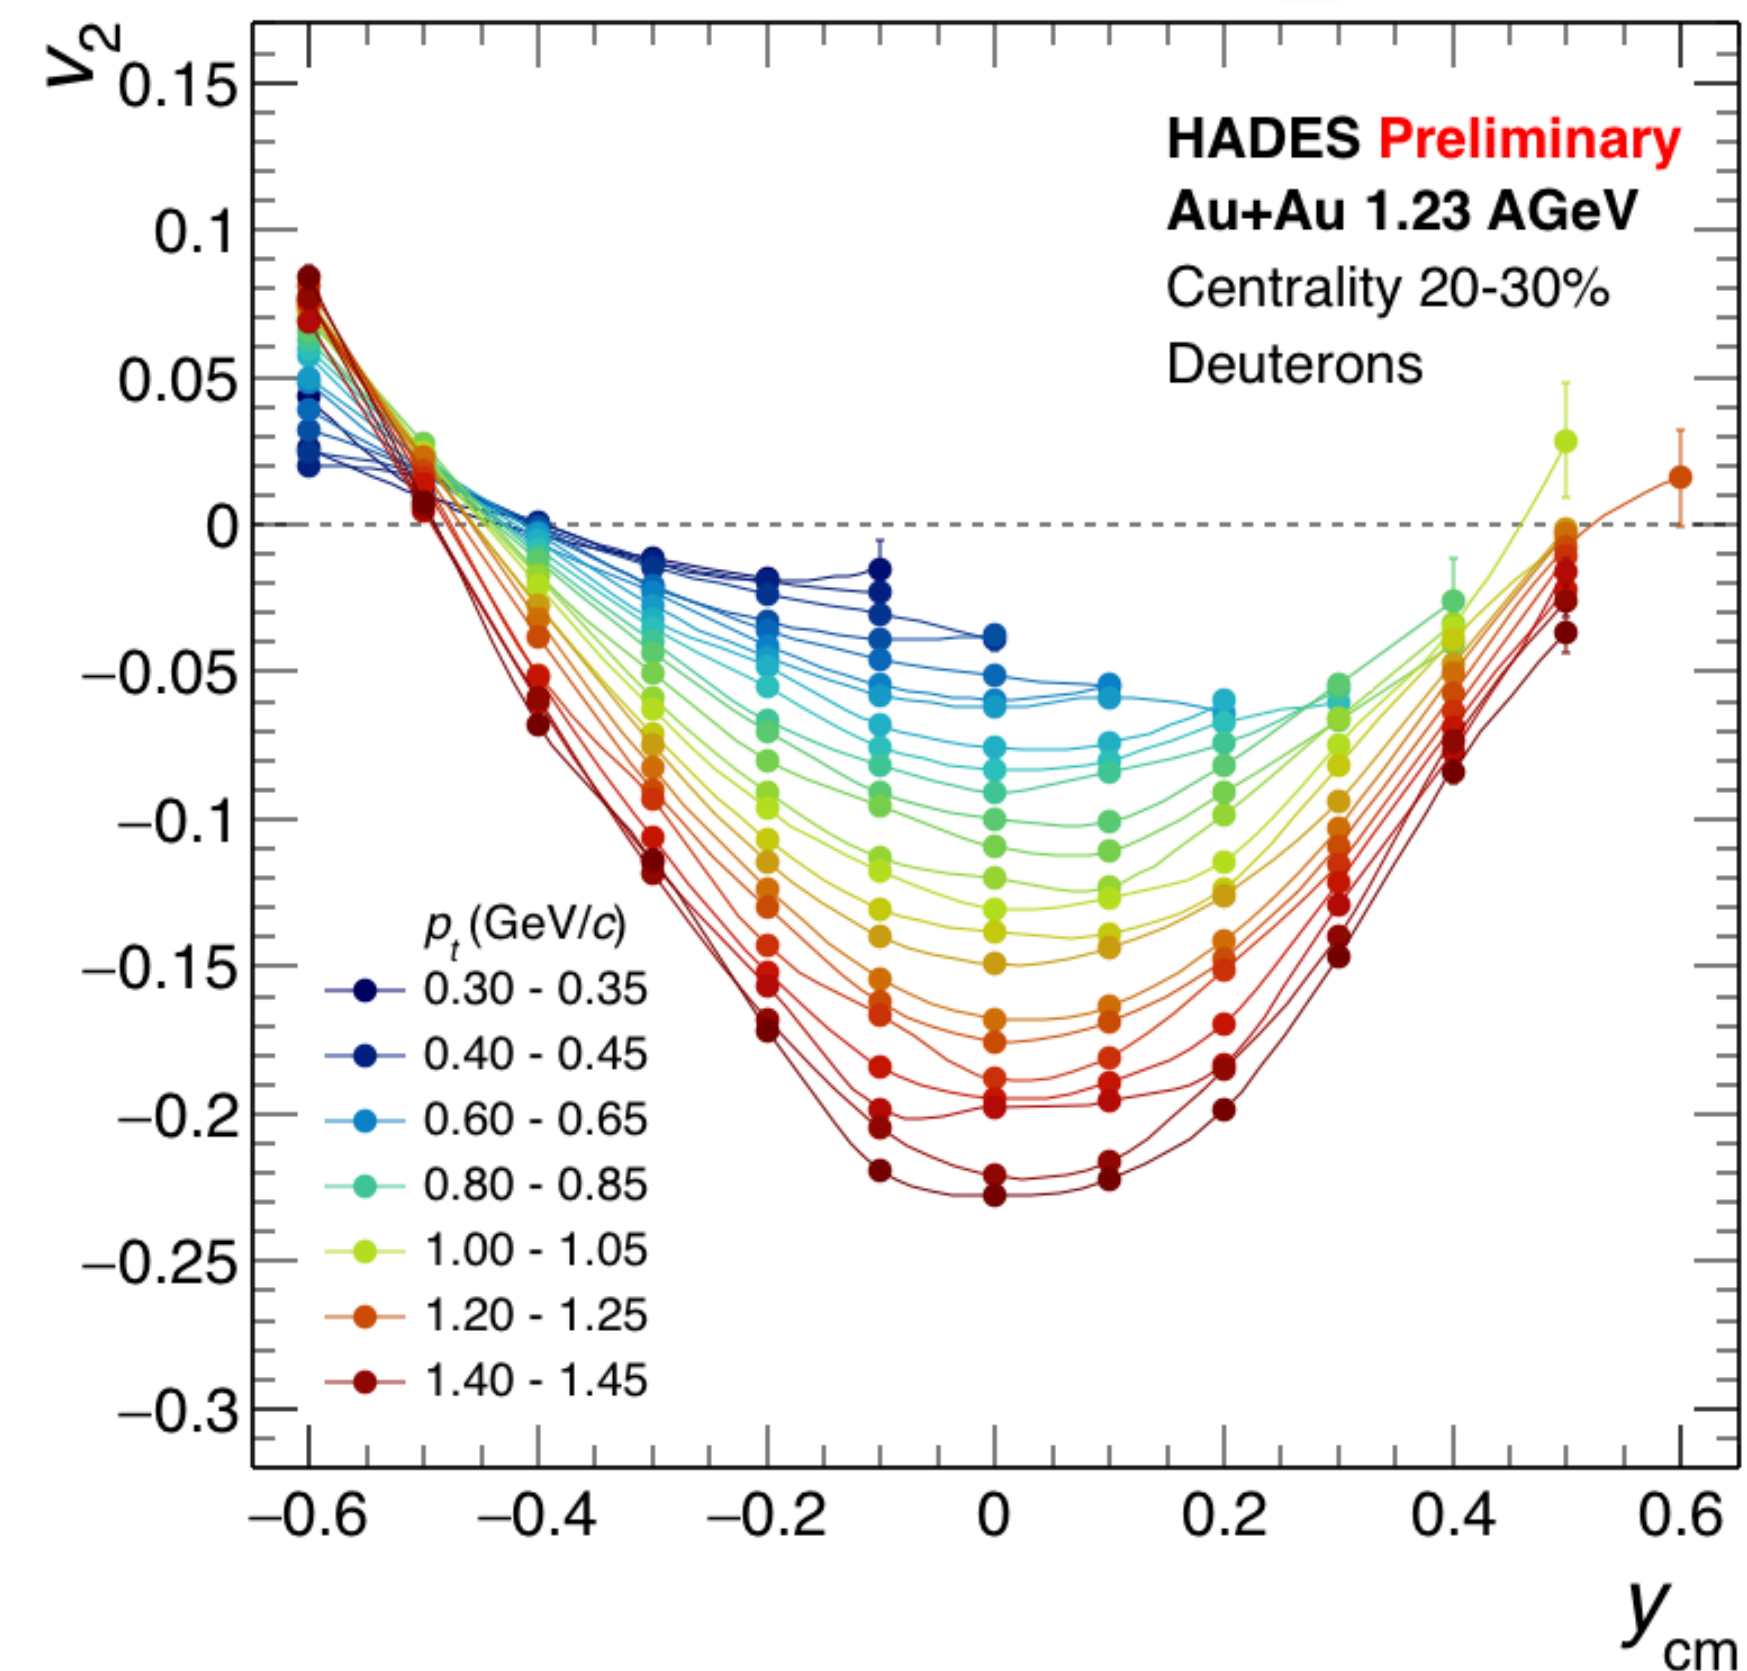

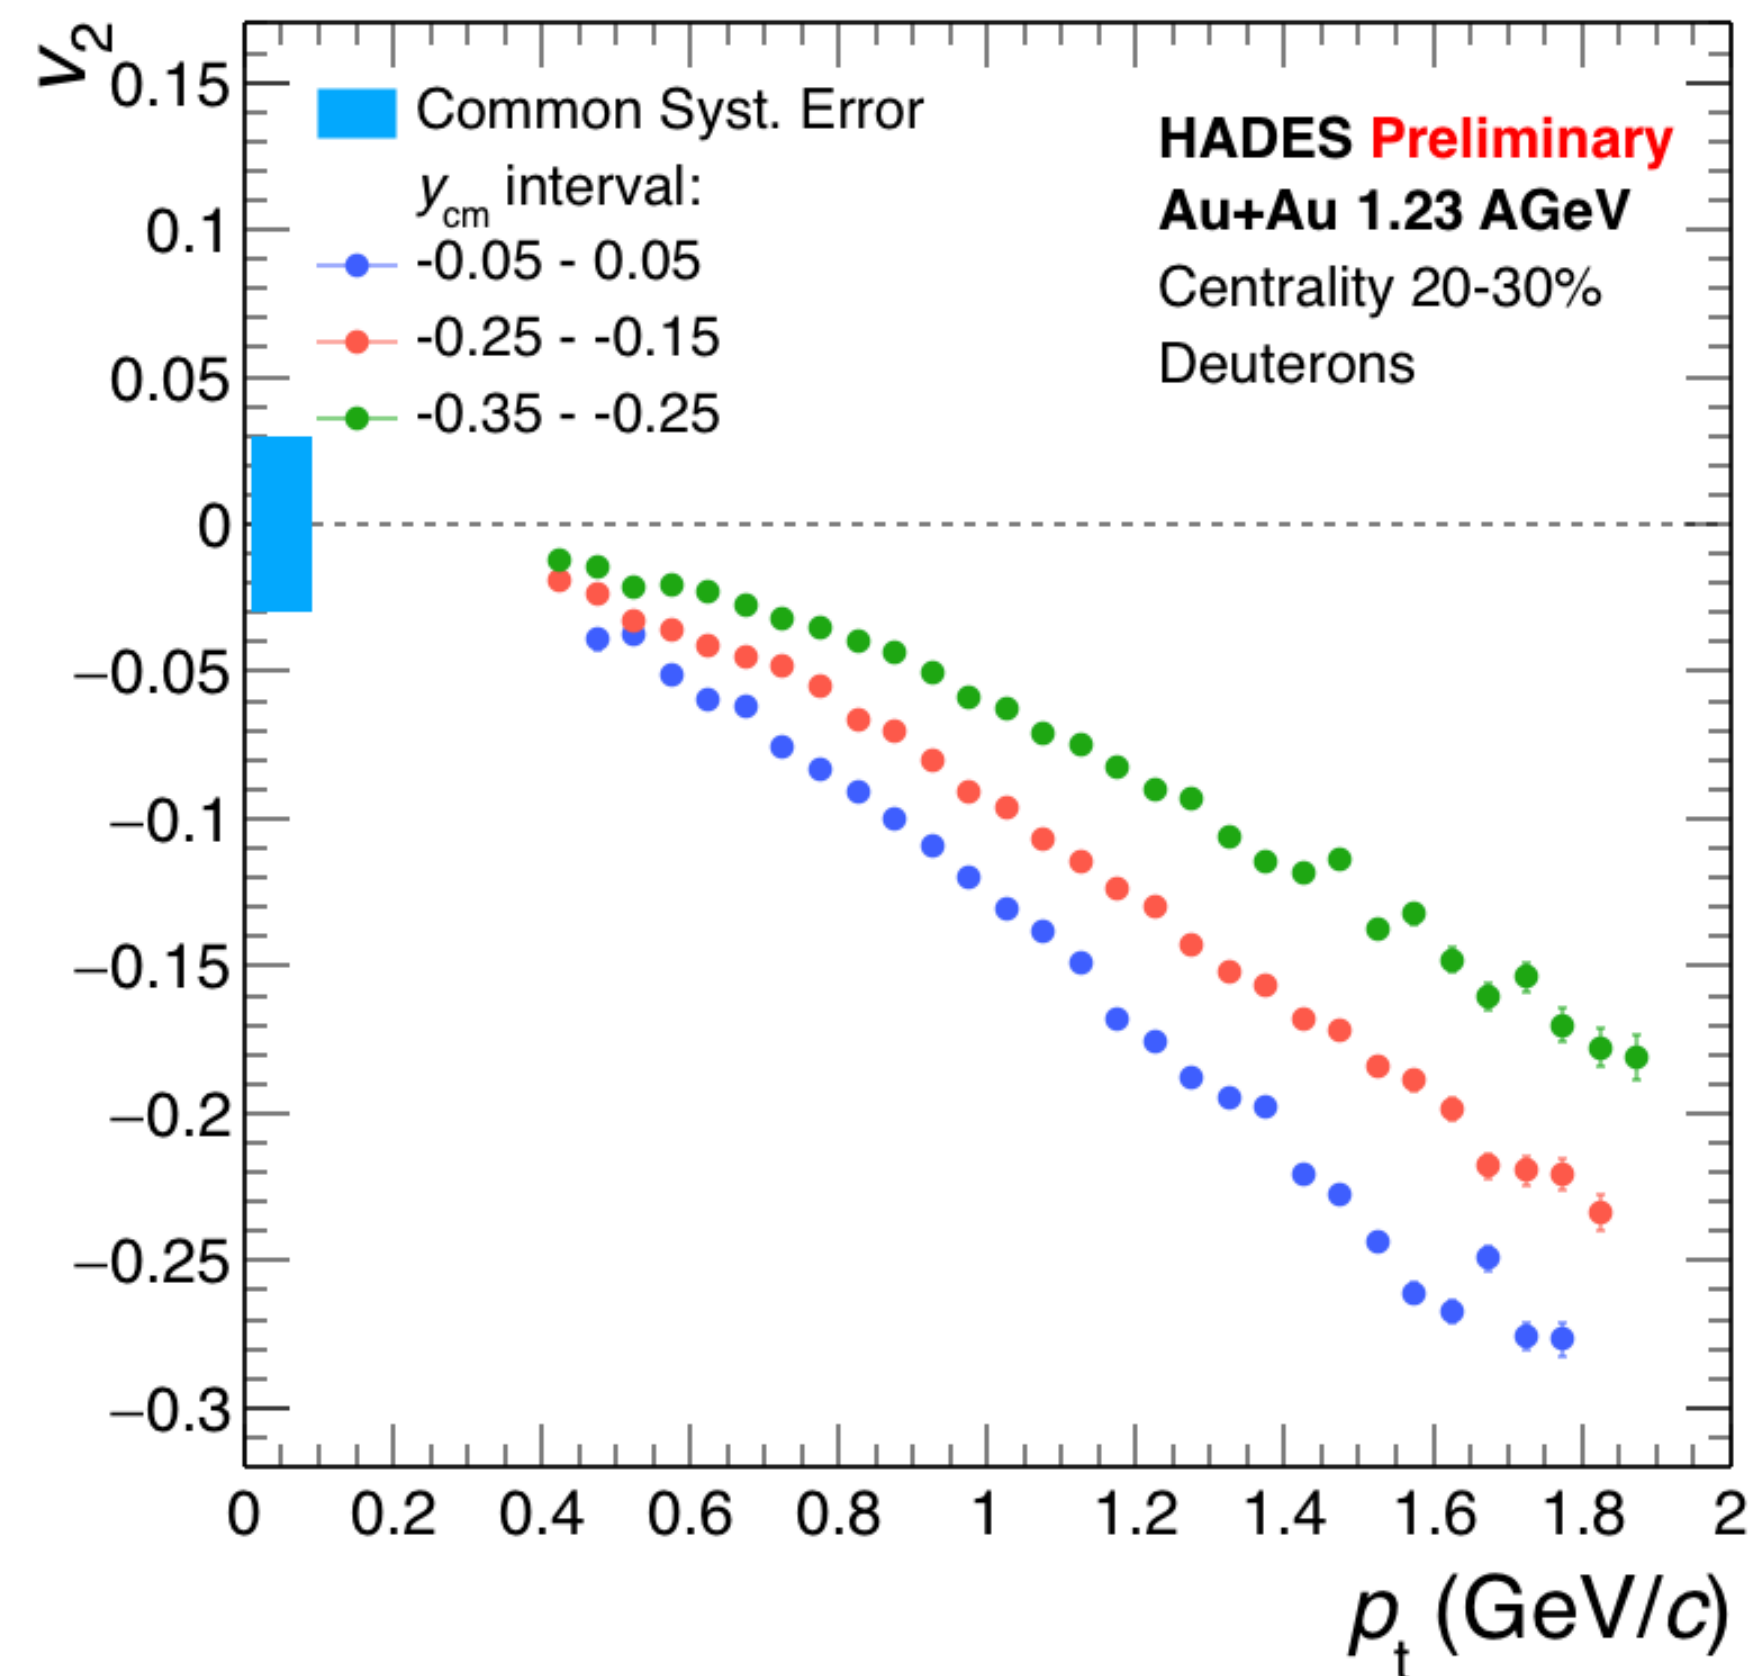

- In pp (and p-Pb) the results point out that the rise in the **number of nucleons dominates over the increase in the volume size**
- No significant centrality dependence in Pb-Pb collisions in agreement with Thermal-statistical model

# d/p ratio: coalescence in UrQMD and SHM

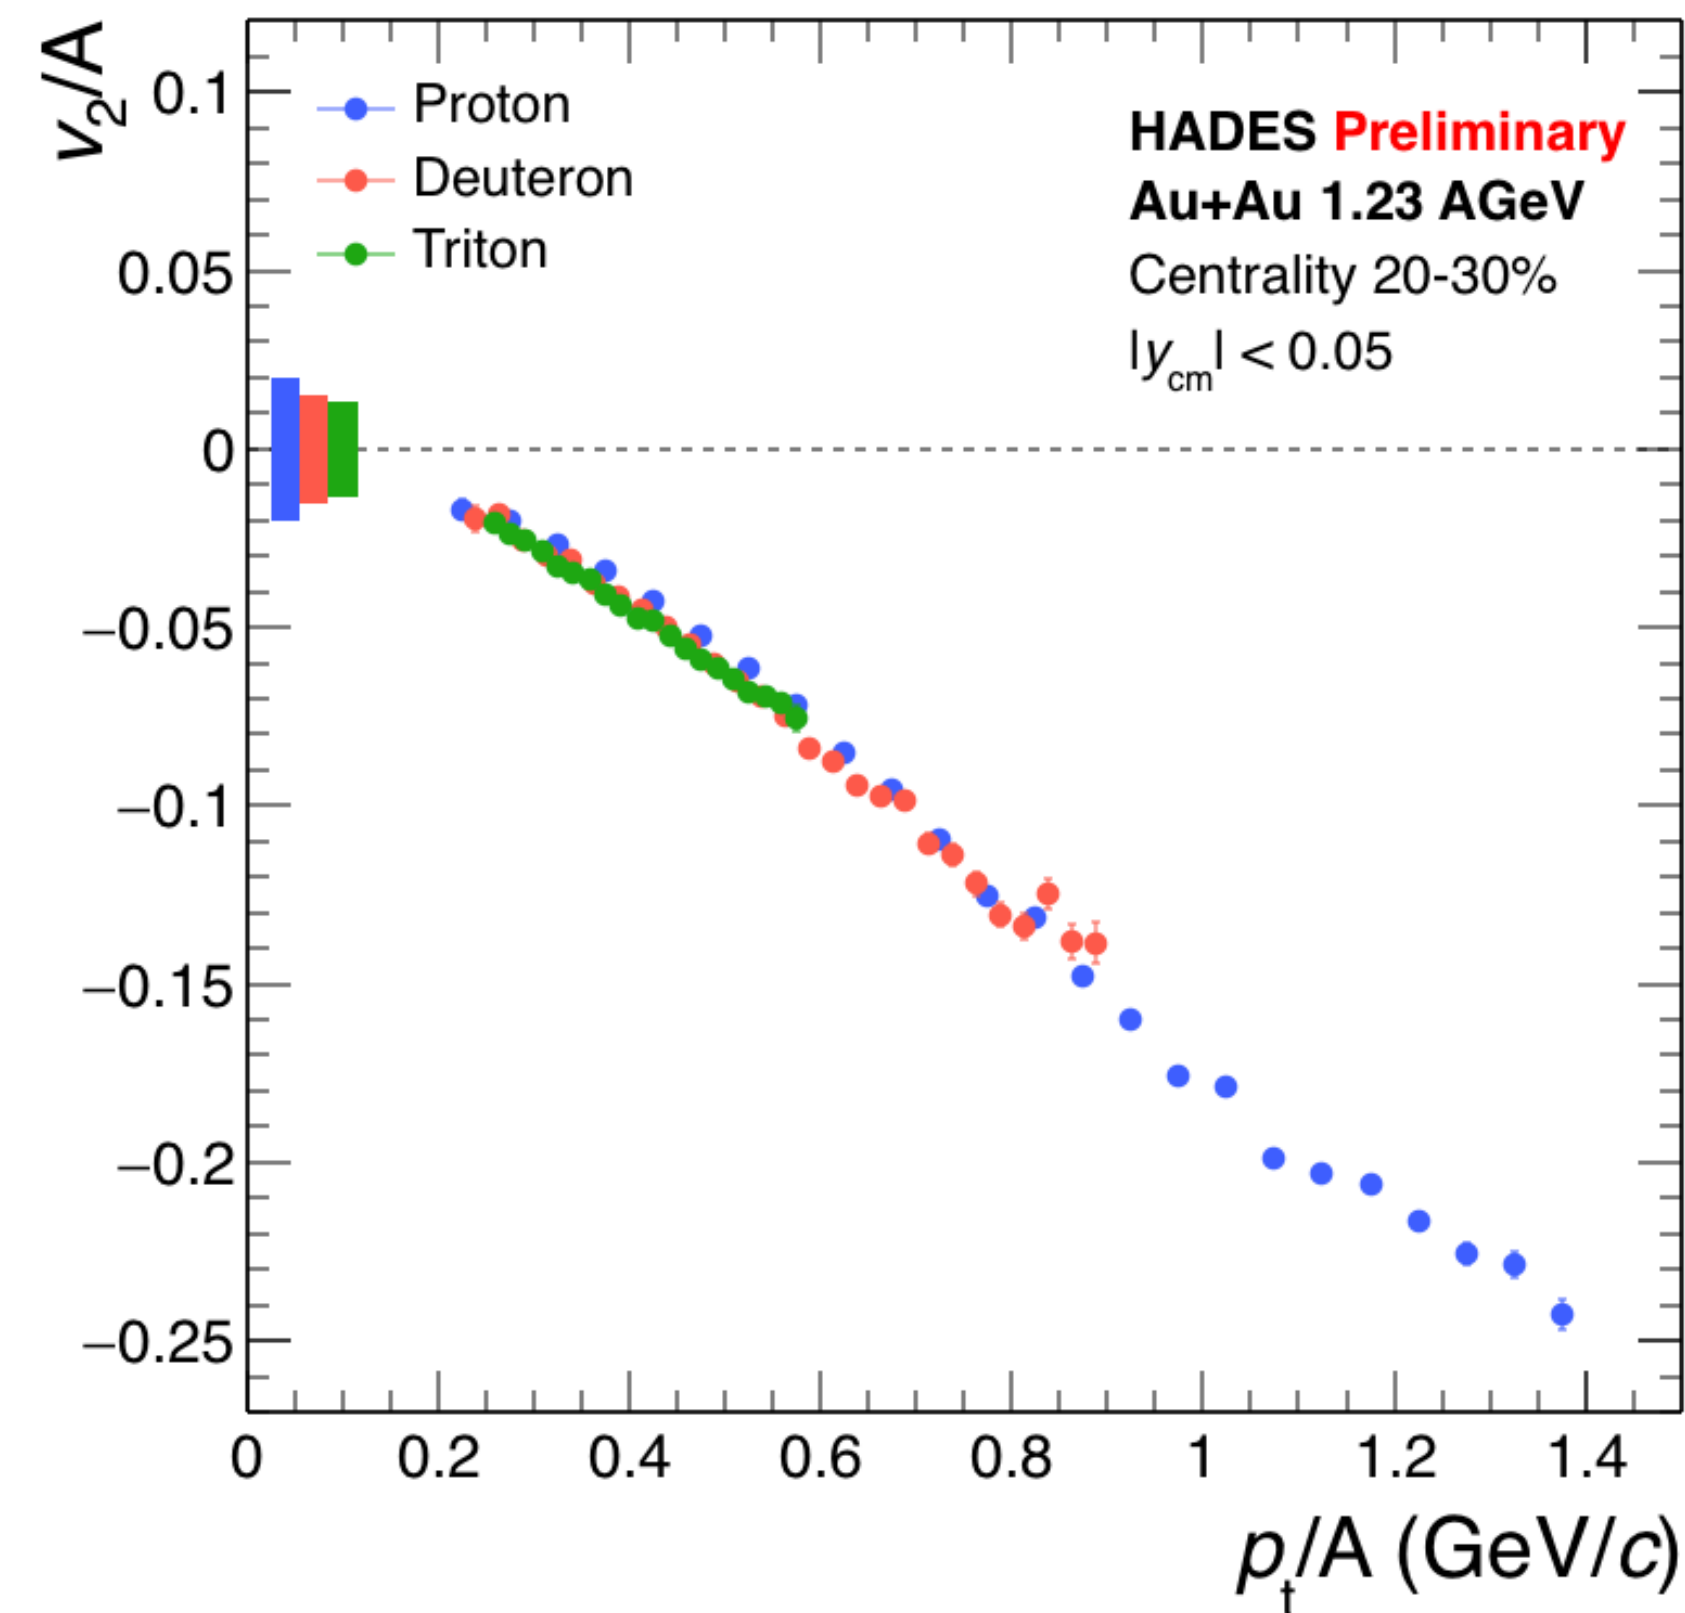

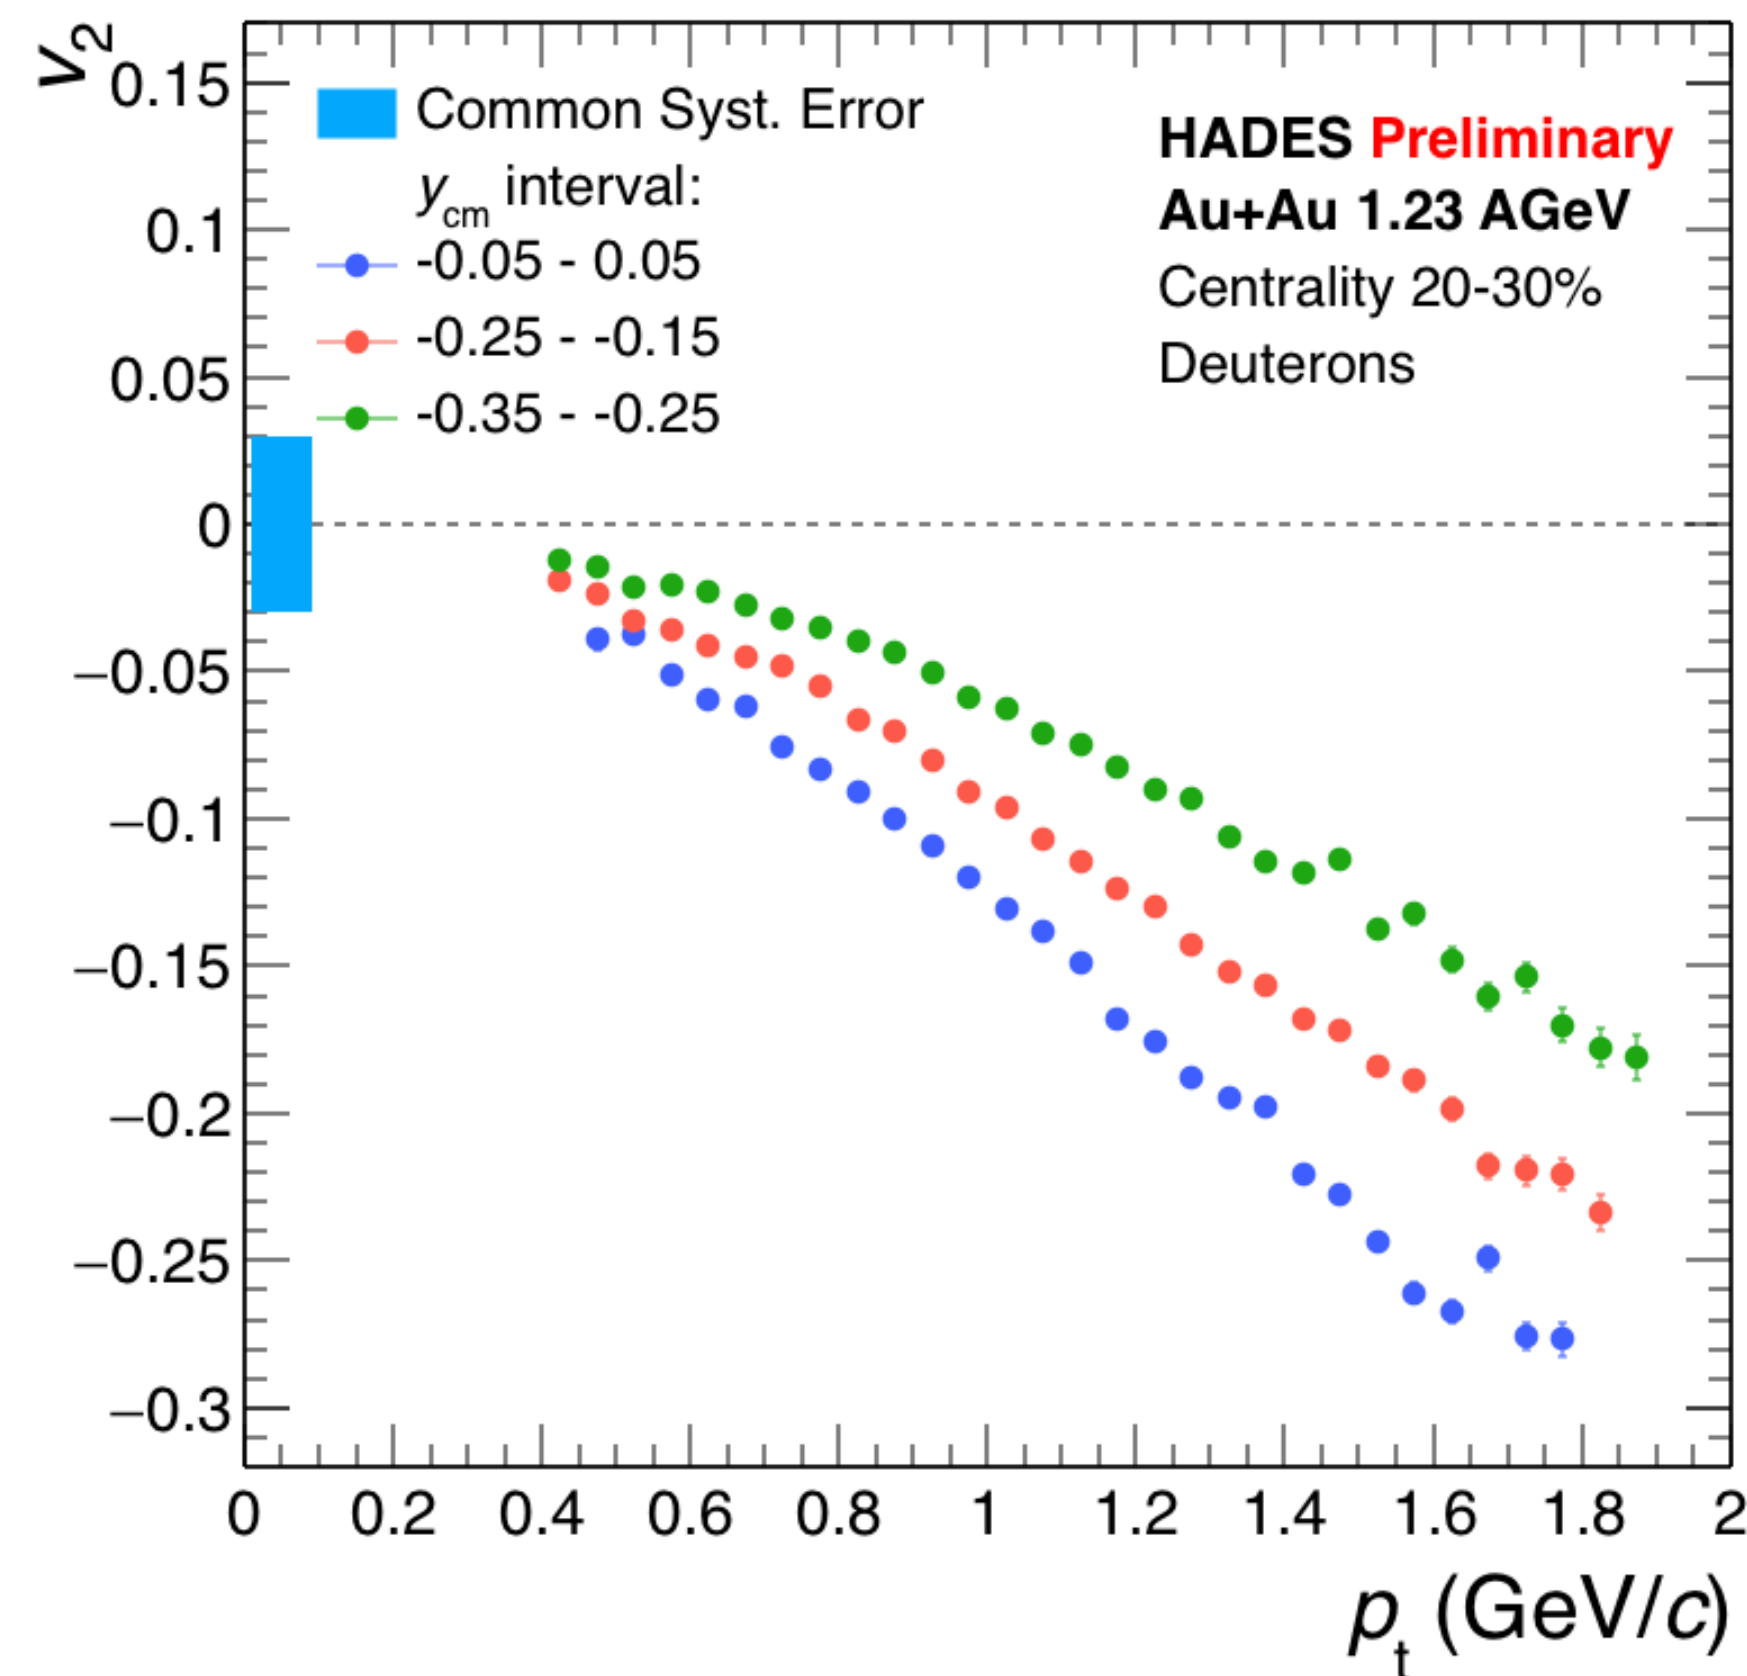

# Elliptic flow with HADES

Latest news

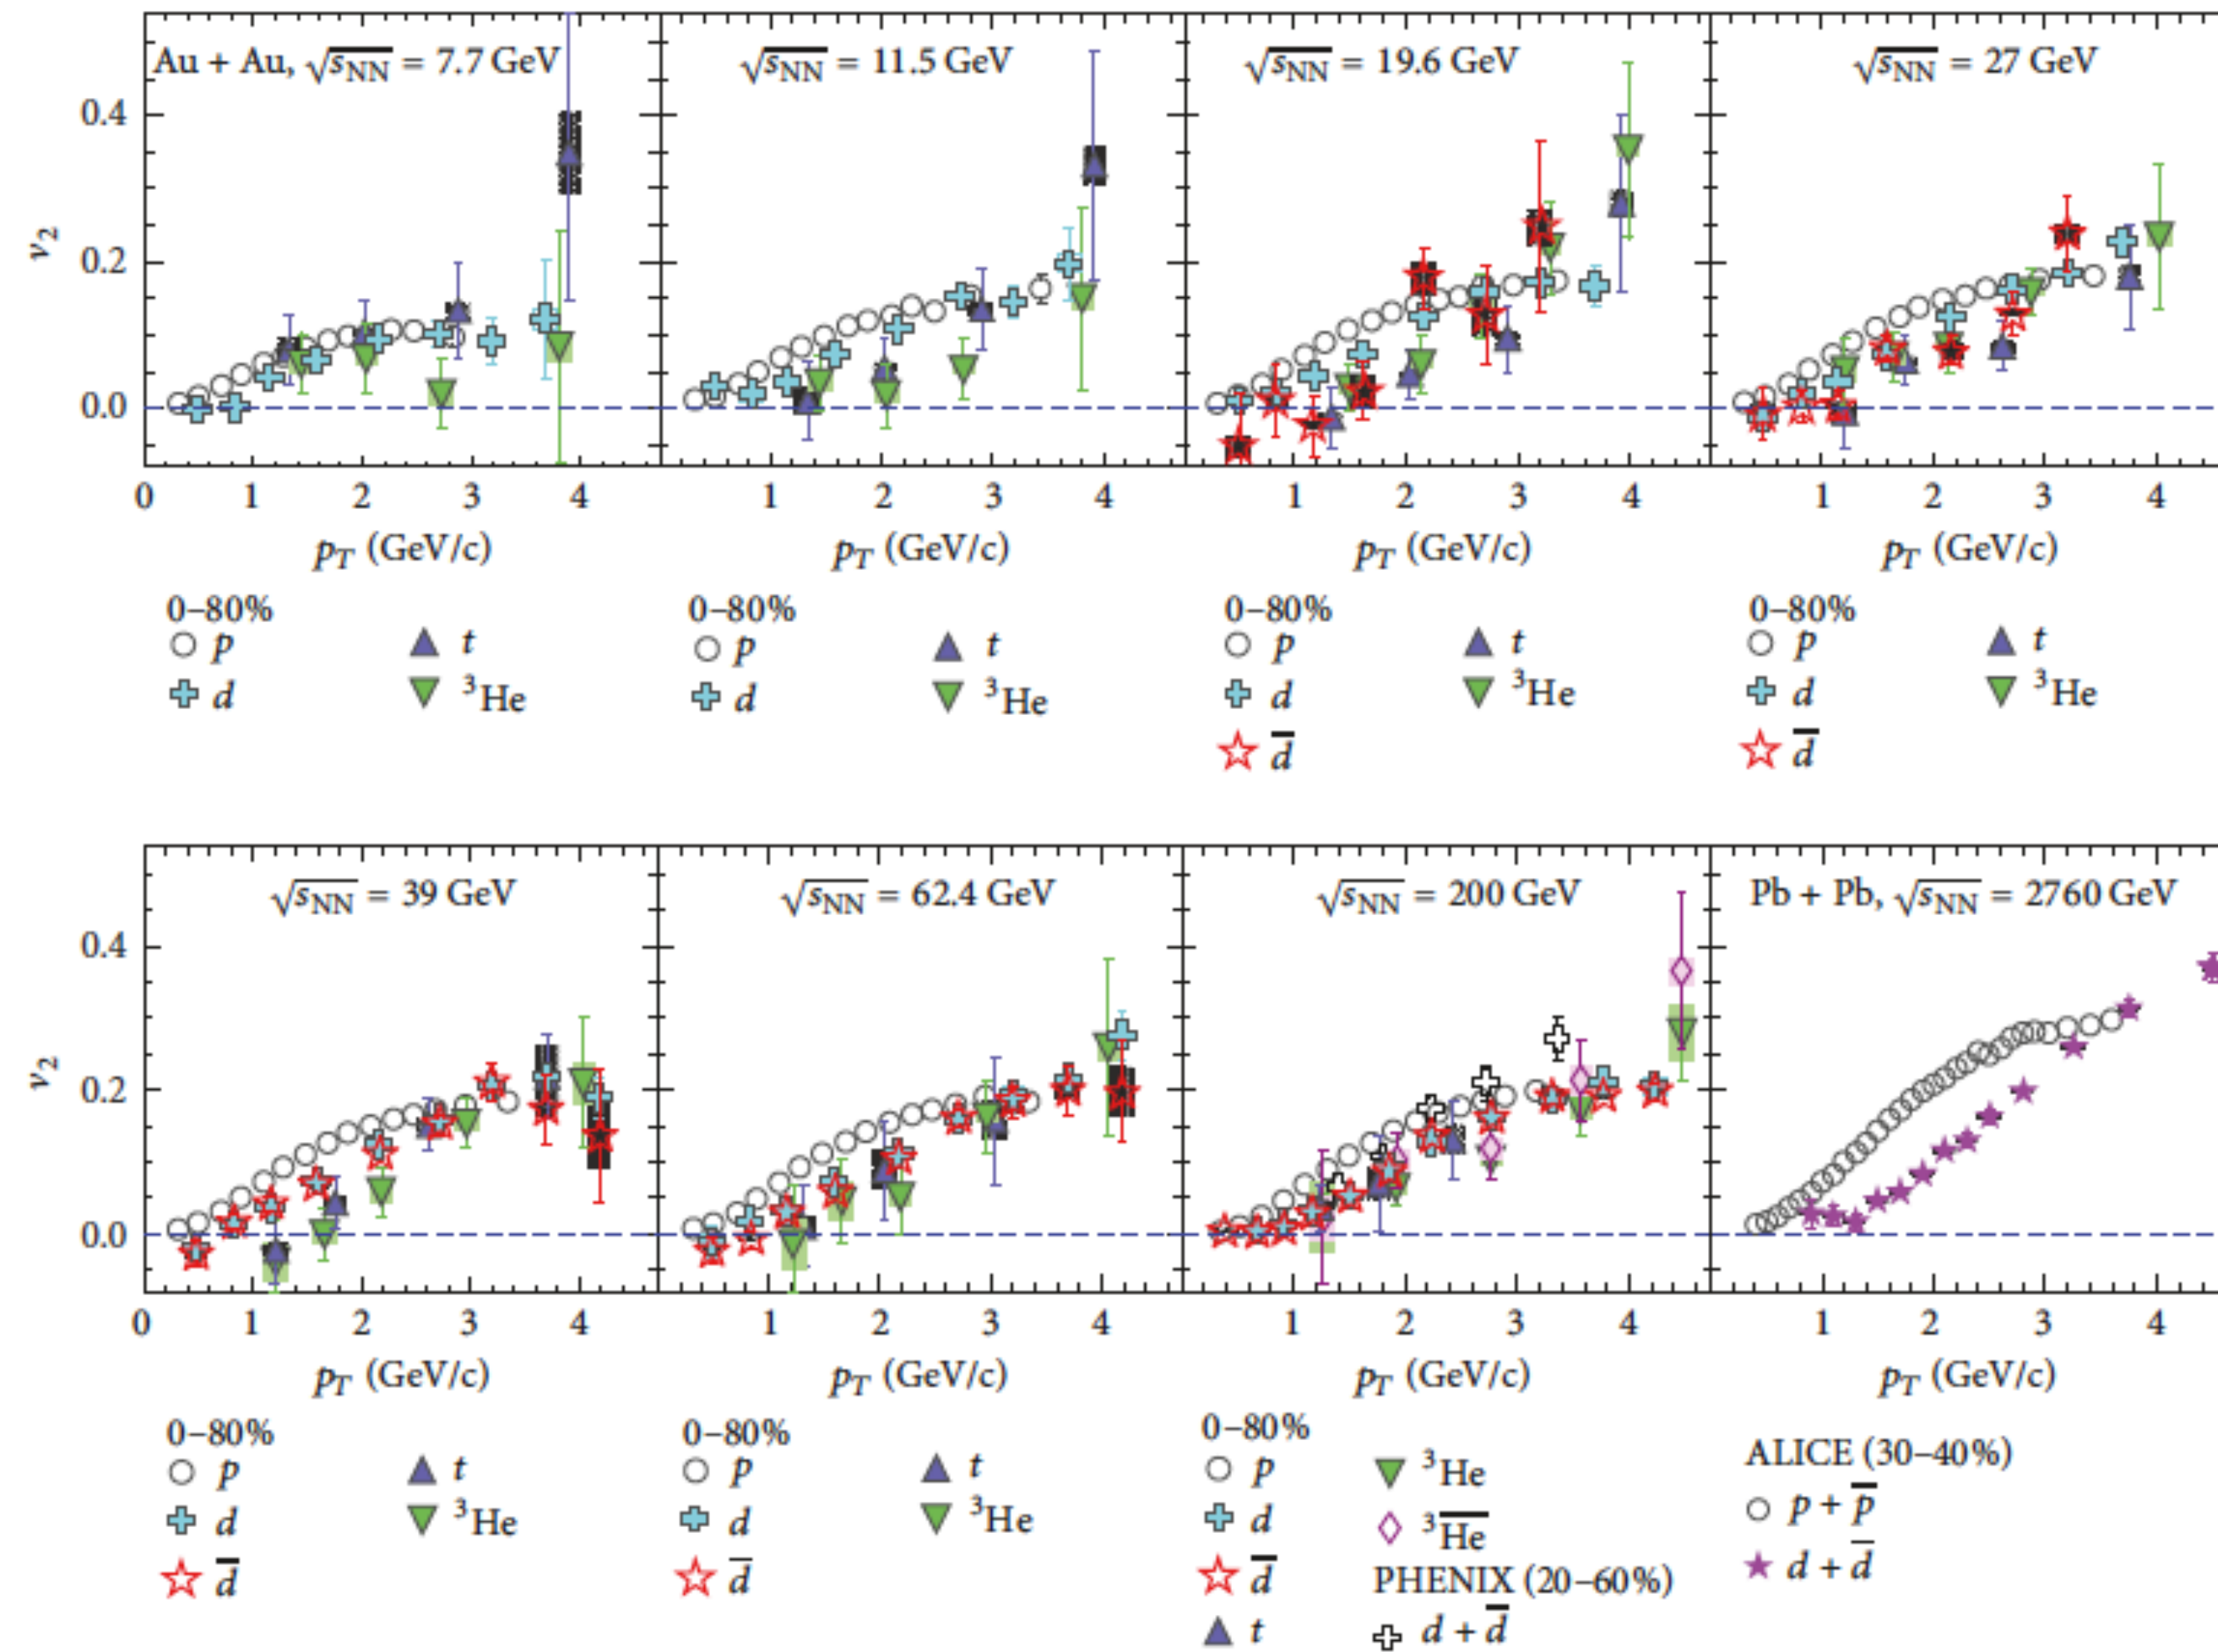

Latest news

- Comparison of p, d, t elliptic flow at mid-rapidity
- Scaling of  $v_2$  and  $p_T$  with nuclear mass number A as expected for nucleon coalescence

Increasing energy →

Increasing energy ↓

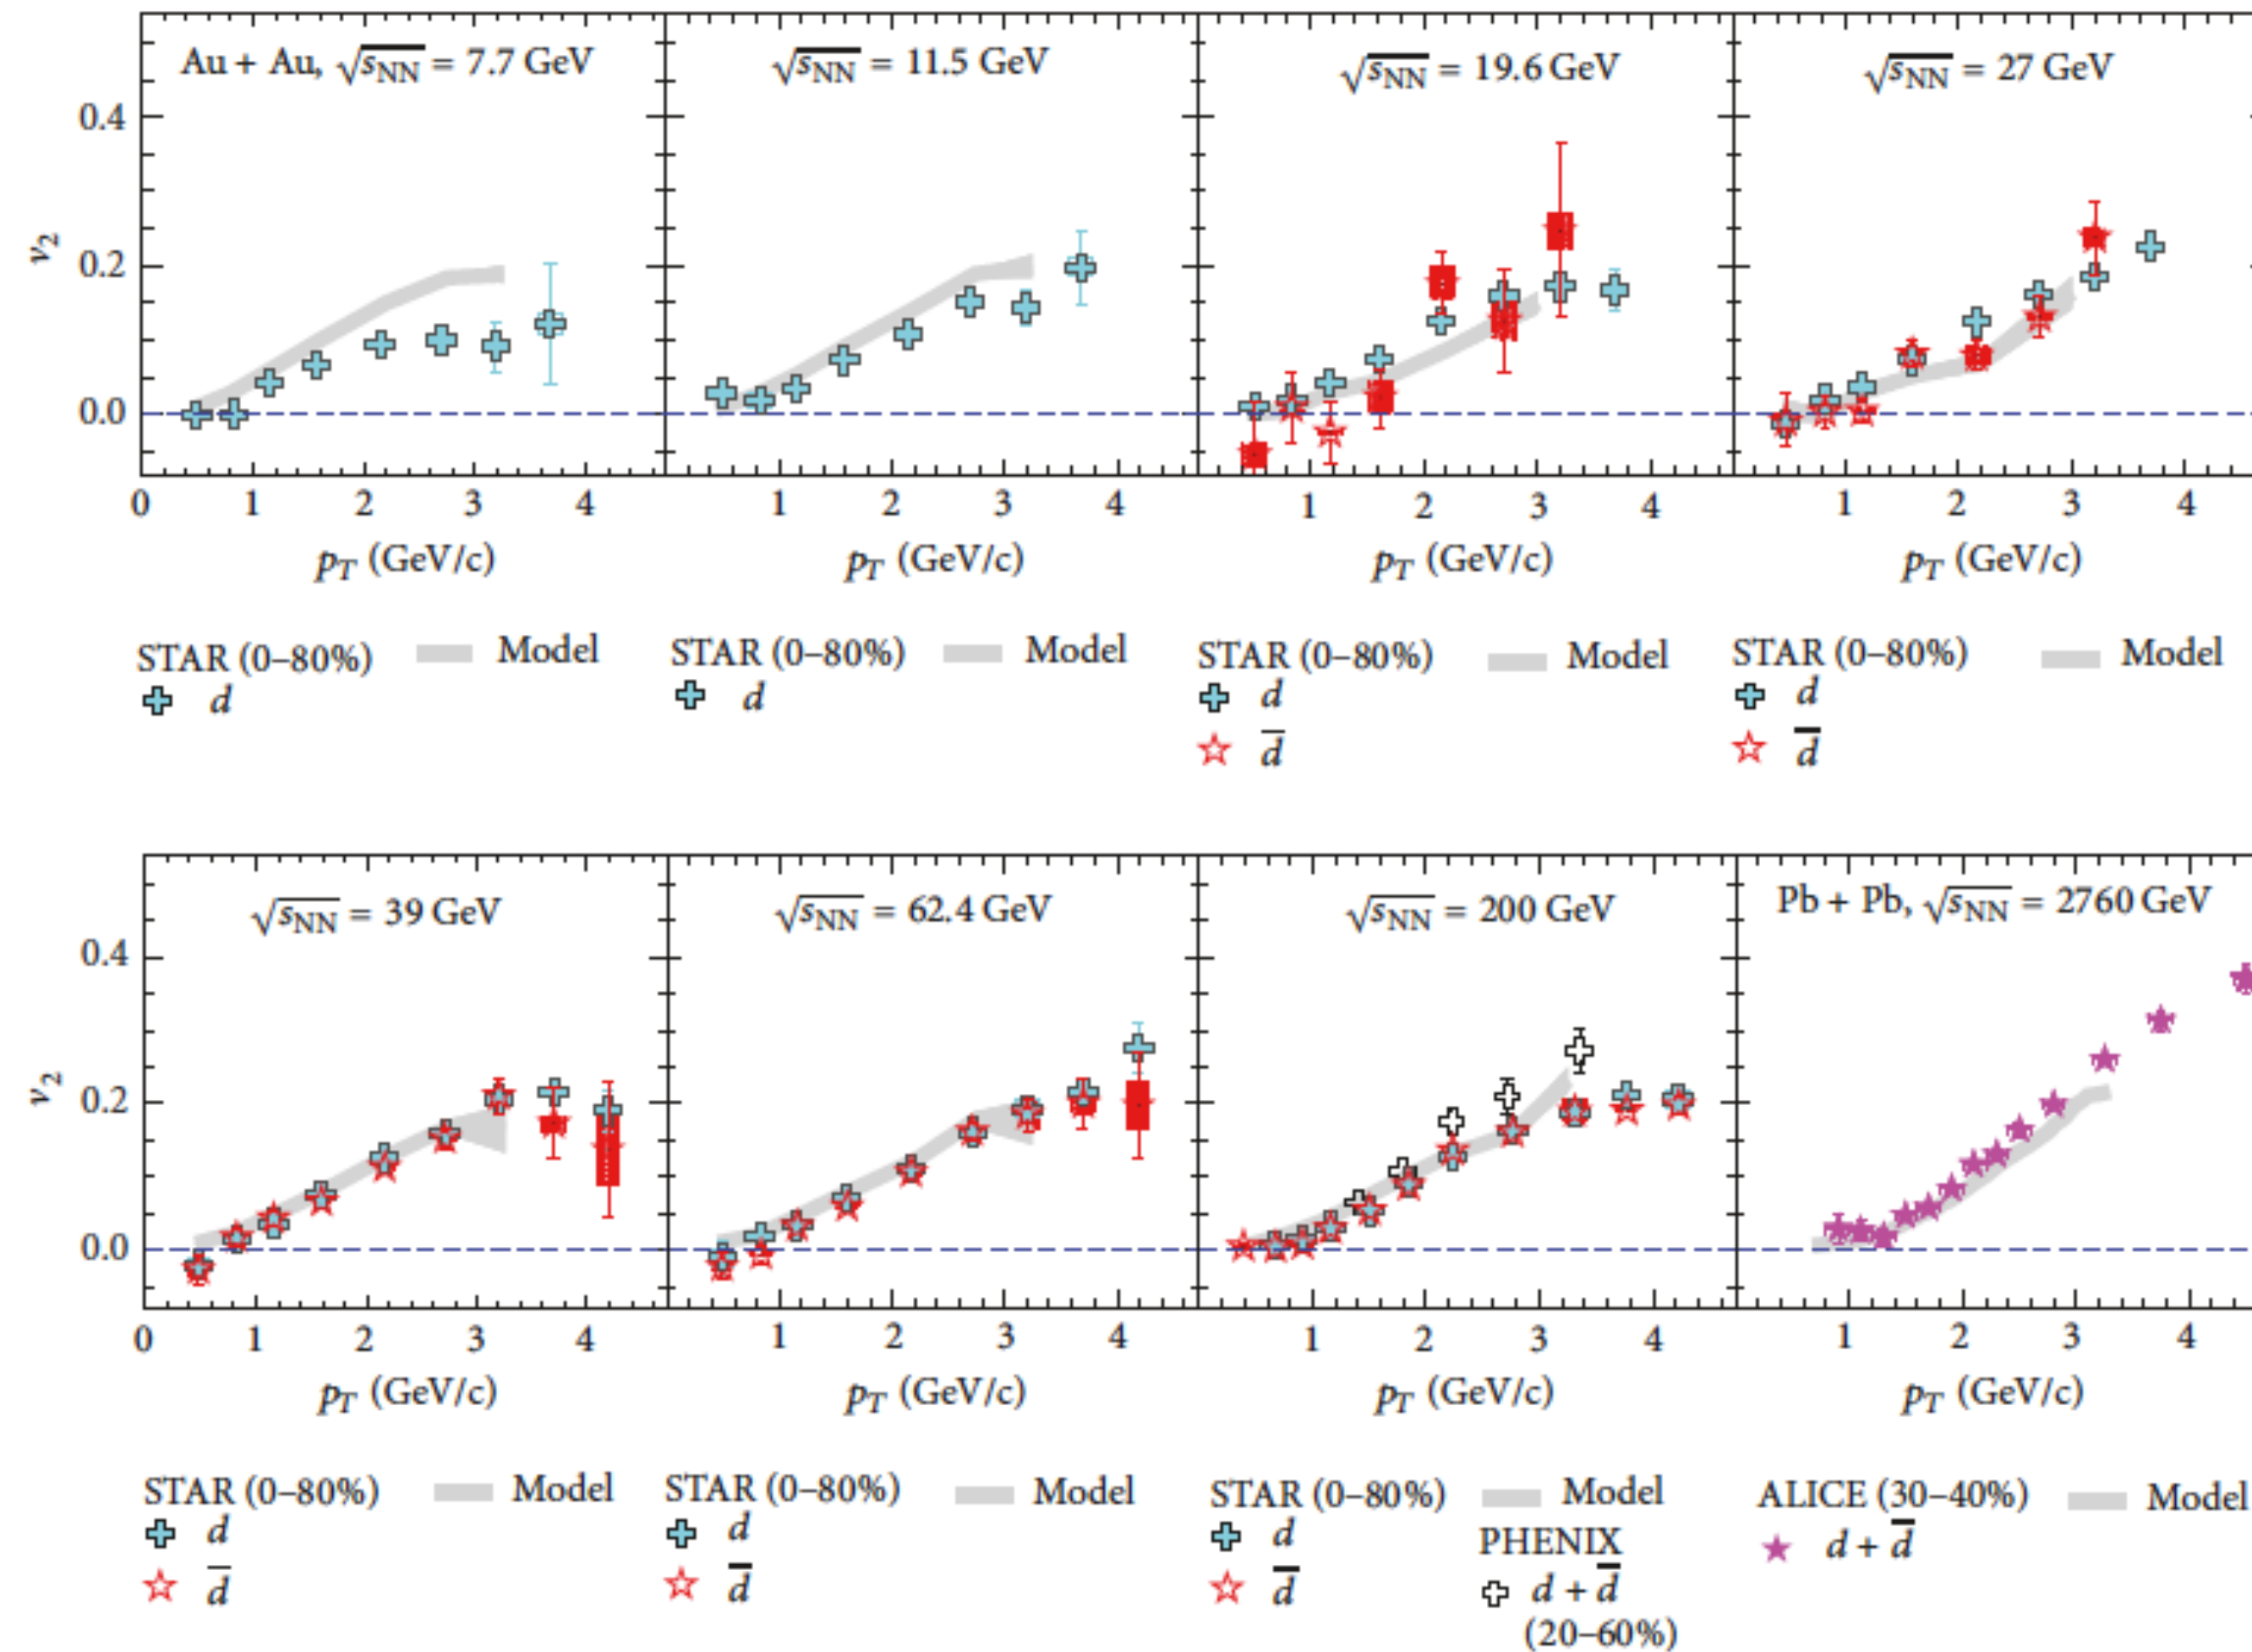

- All species shows similar trend vs  $p_T$
- $v_2$  of light nuclei shows a mass ordering in particular at low  $p_T$

# Nuclei elliptic flow from ALICE, PHENIX and STAR

Increasing energy →

Increasing energy ↓

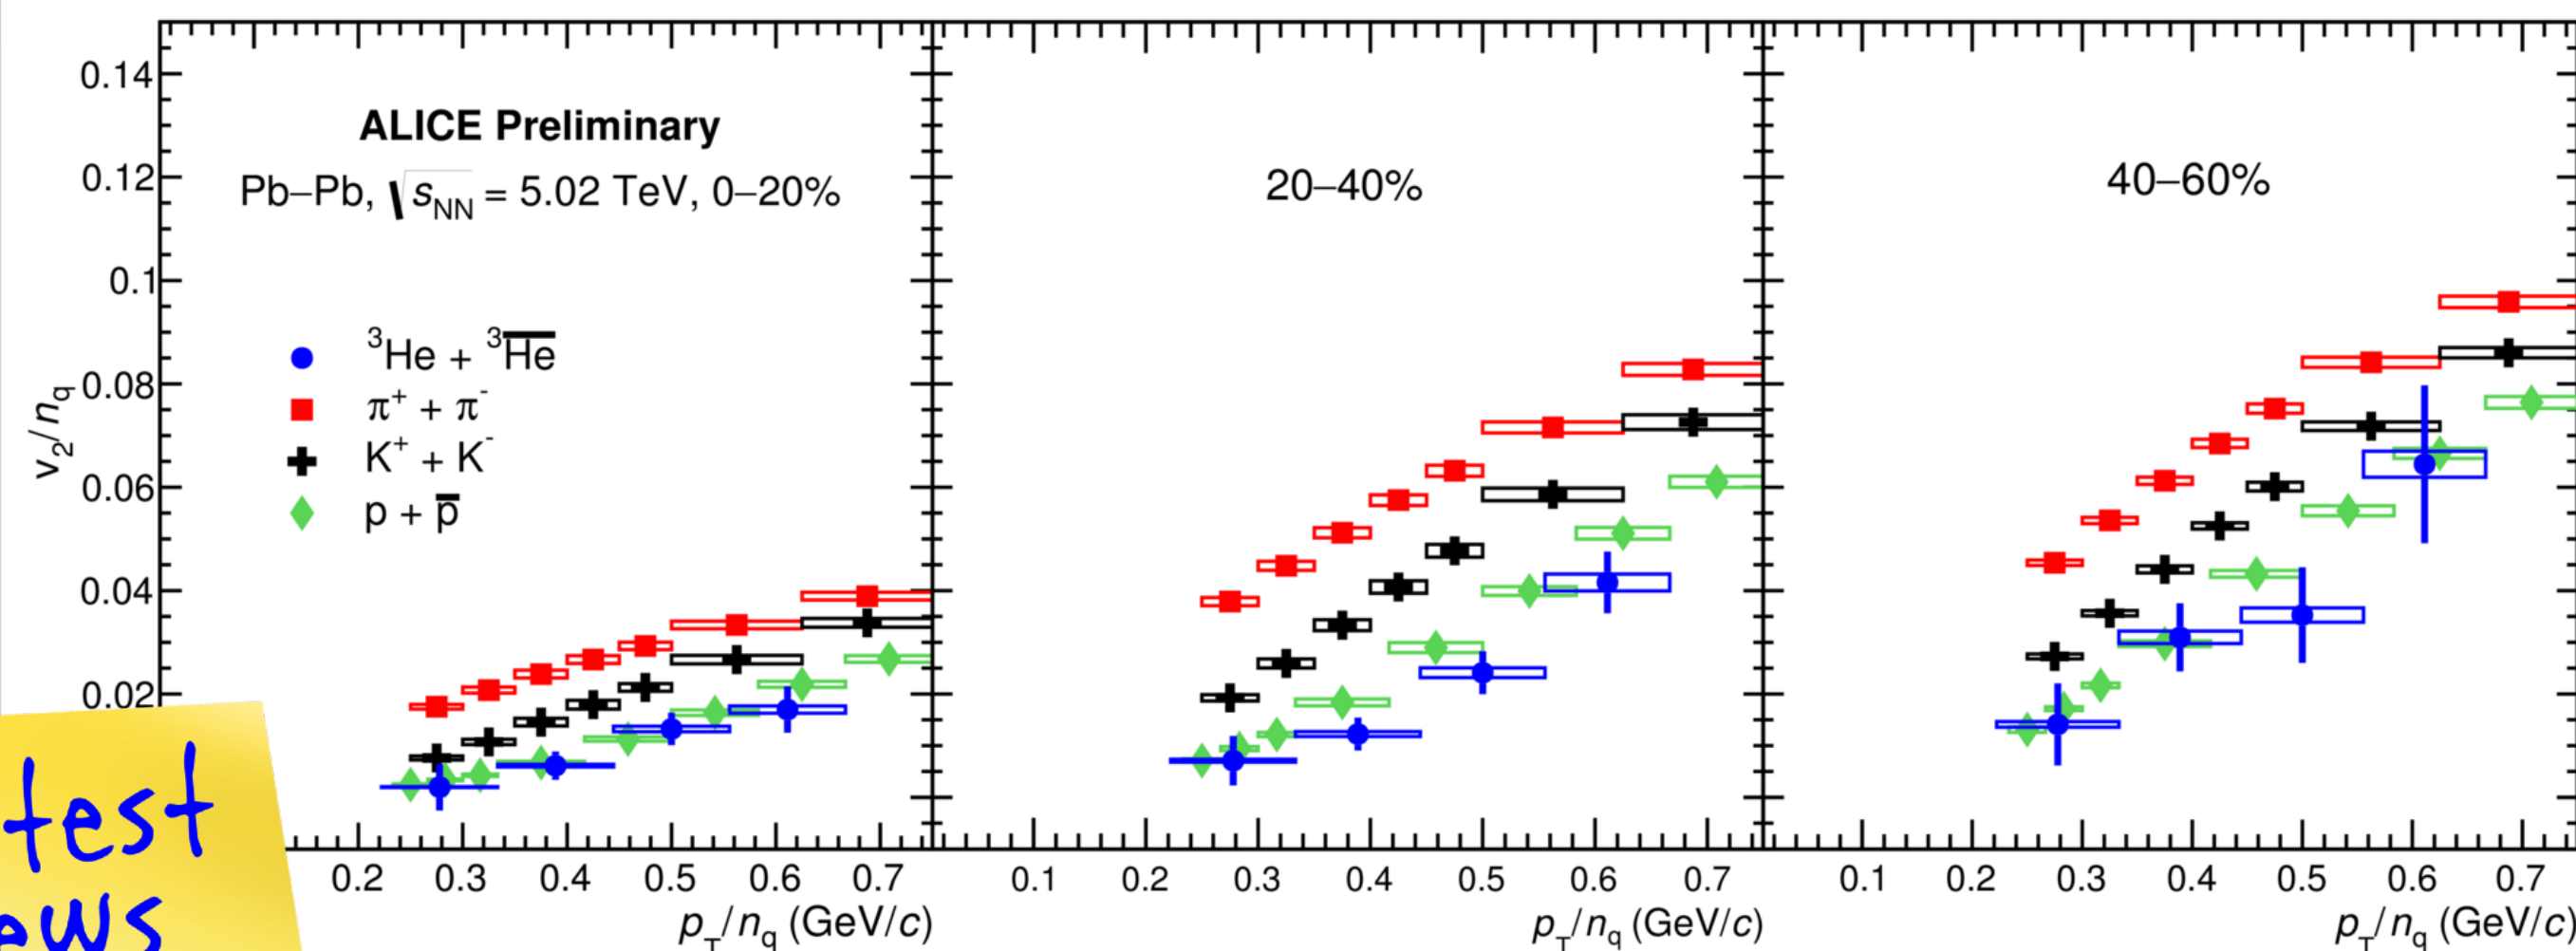

- mass ordering: expectation typical of thermodynamical models
- a hybrid AMPT + coalescence model fairly reproduce the experimental data at higher energies
- at the LHC energies B-W models reproduce the data

precise measurements of  $^3\text{He}$  and  $^4\text{He}$   $v_2$  can shed light on the nuclei production mechanism in heavy-ion collisions

# The heaviest stable anti-nucleus observed

## anti-<sup>4</sup>He track in the STAR detector

STAR PID for (anti-nuclei)

The STAR Collaboration published in 2011 (*Nature* volume 473, pages 353–356) the first observation of anti-<sup>4</sup>He, measured in Au-Au collisions at 200 GeV and 62 GeV per nucleon–nucleon pair.

The measured production yield is consistent with expectations from *thermodynamic*<sup>1</sup> and *coalescence*<sup>2</sup> models

1. Peter Braun-Munzinger, P. & Stachel, J. *Nature* 448, 302–309 (2007).

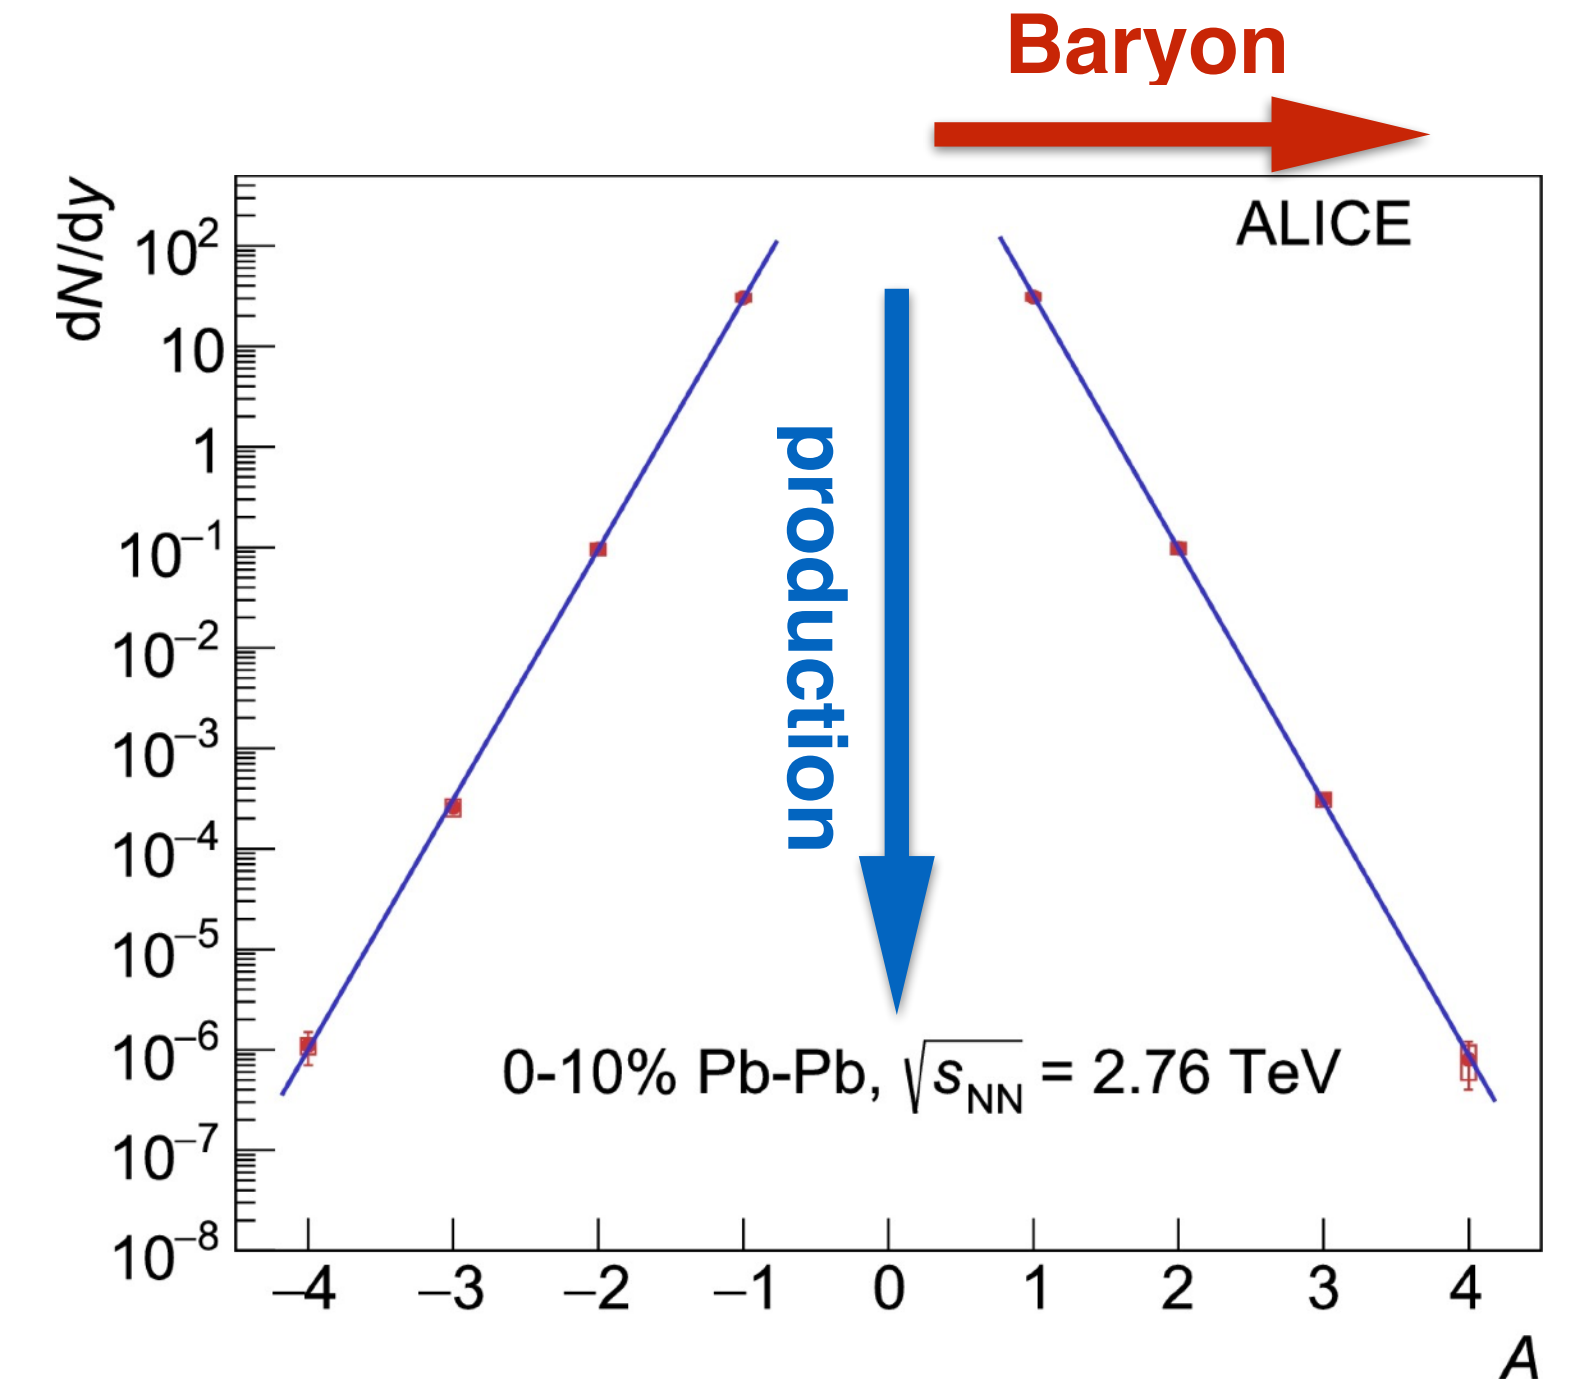

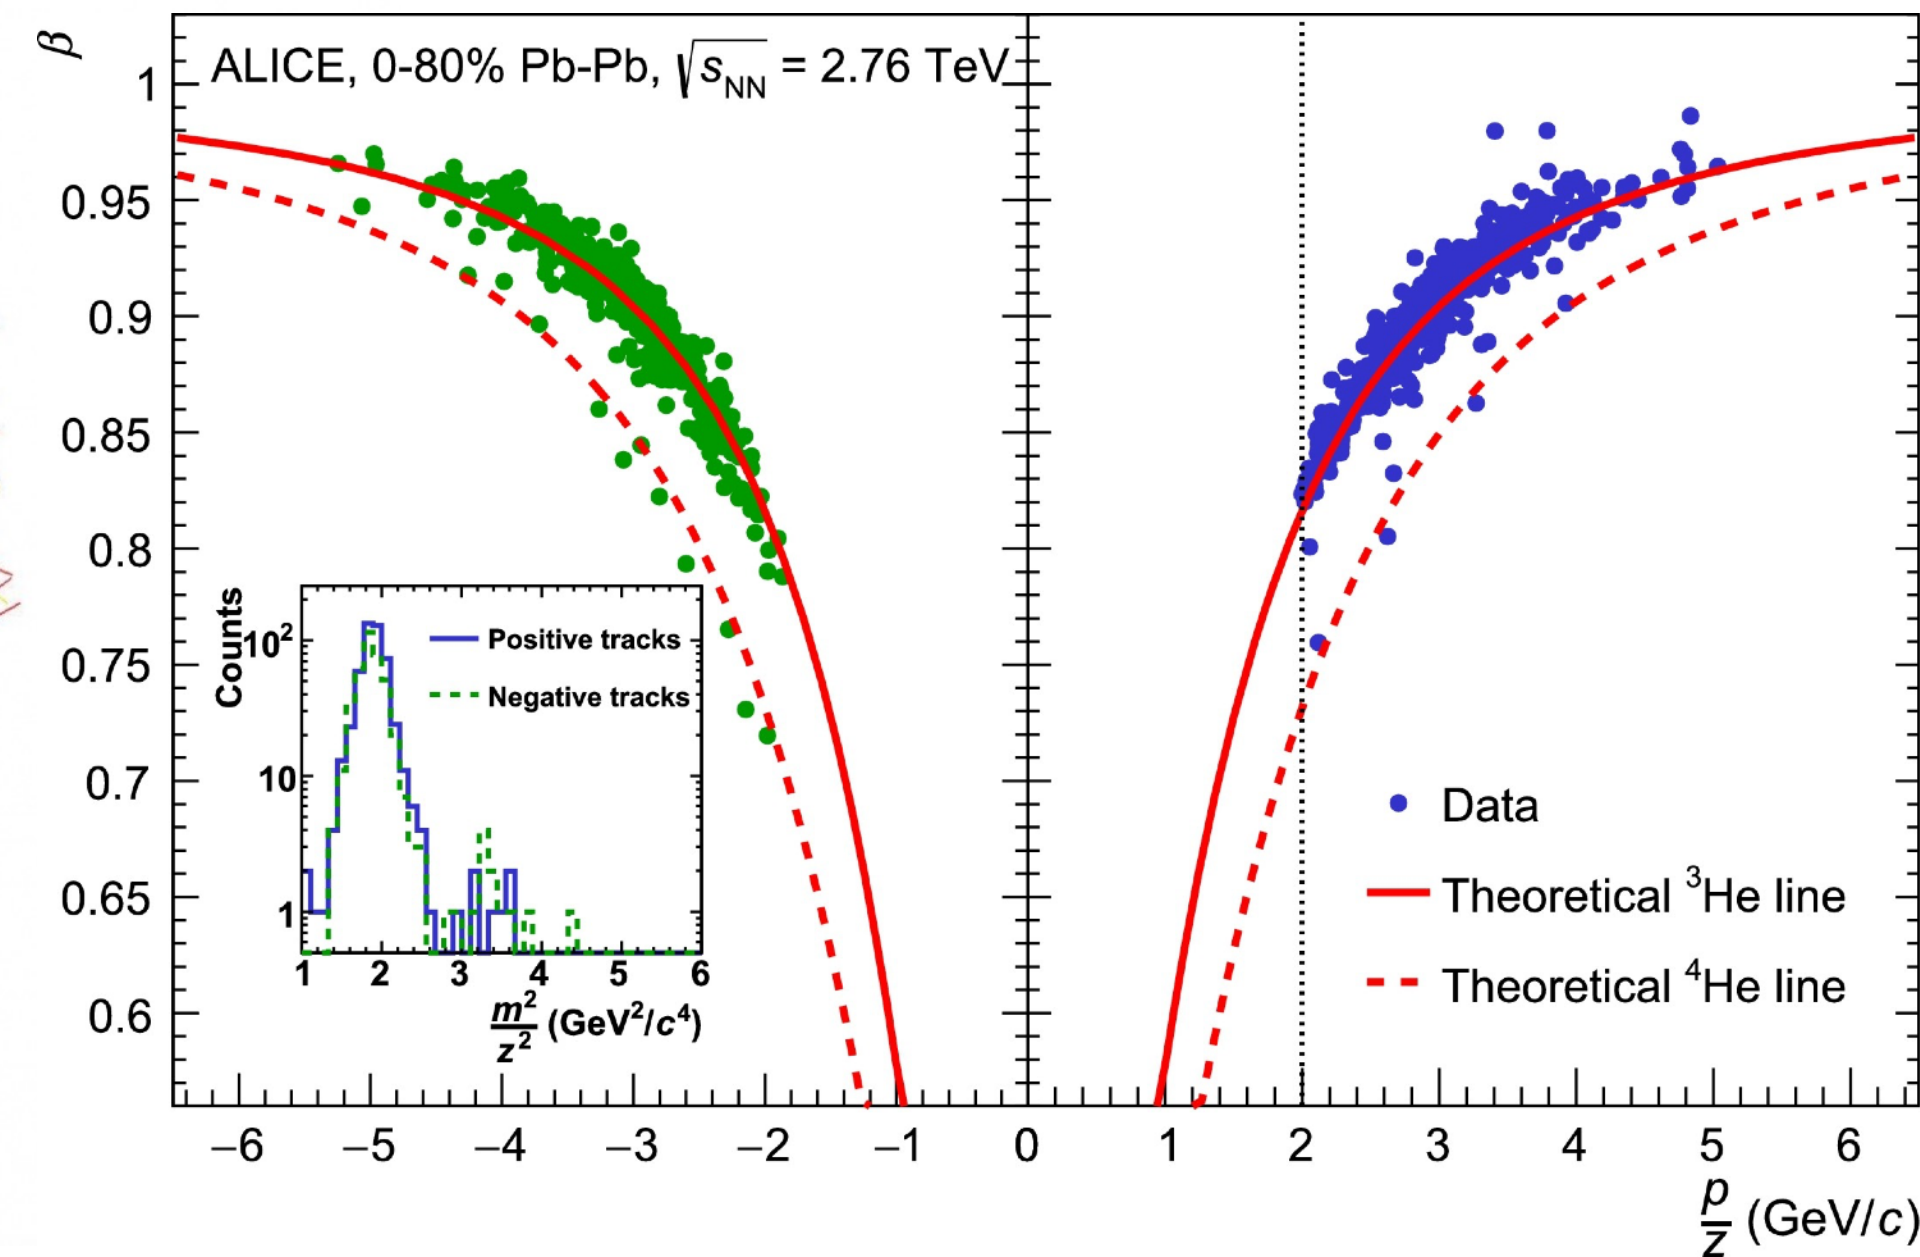

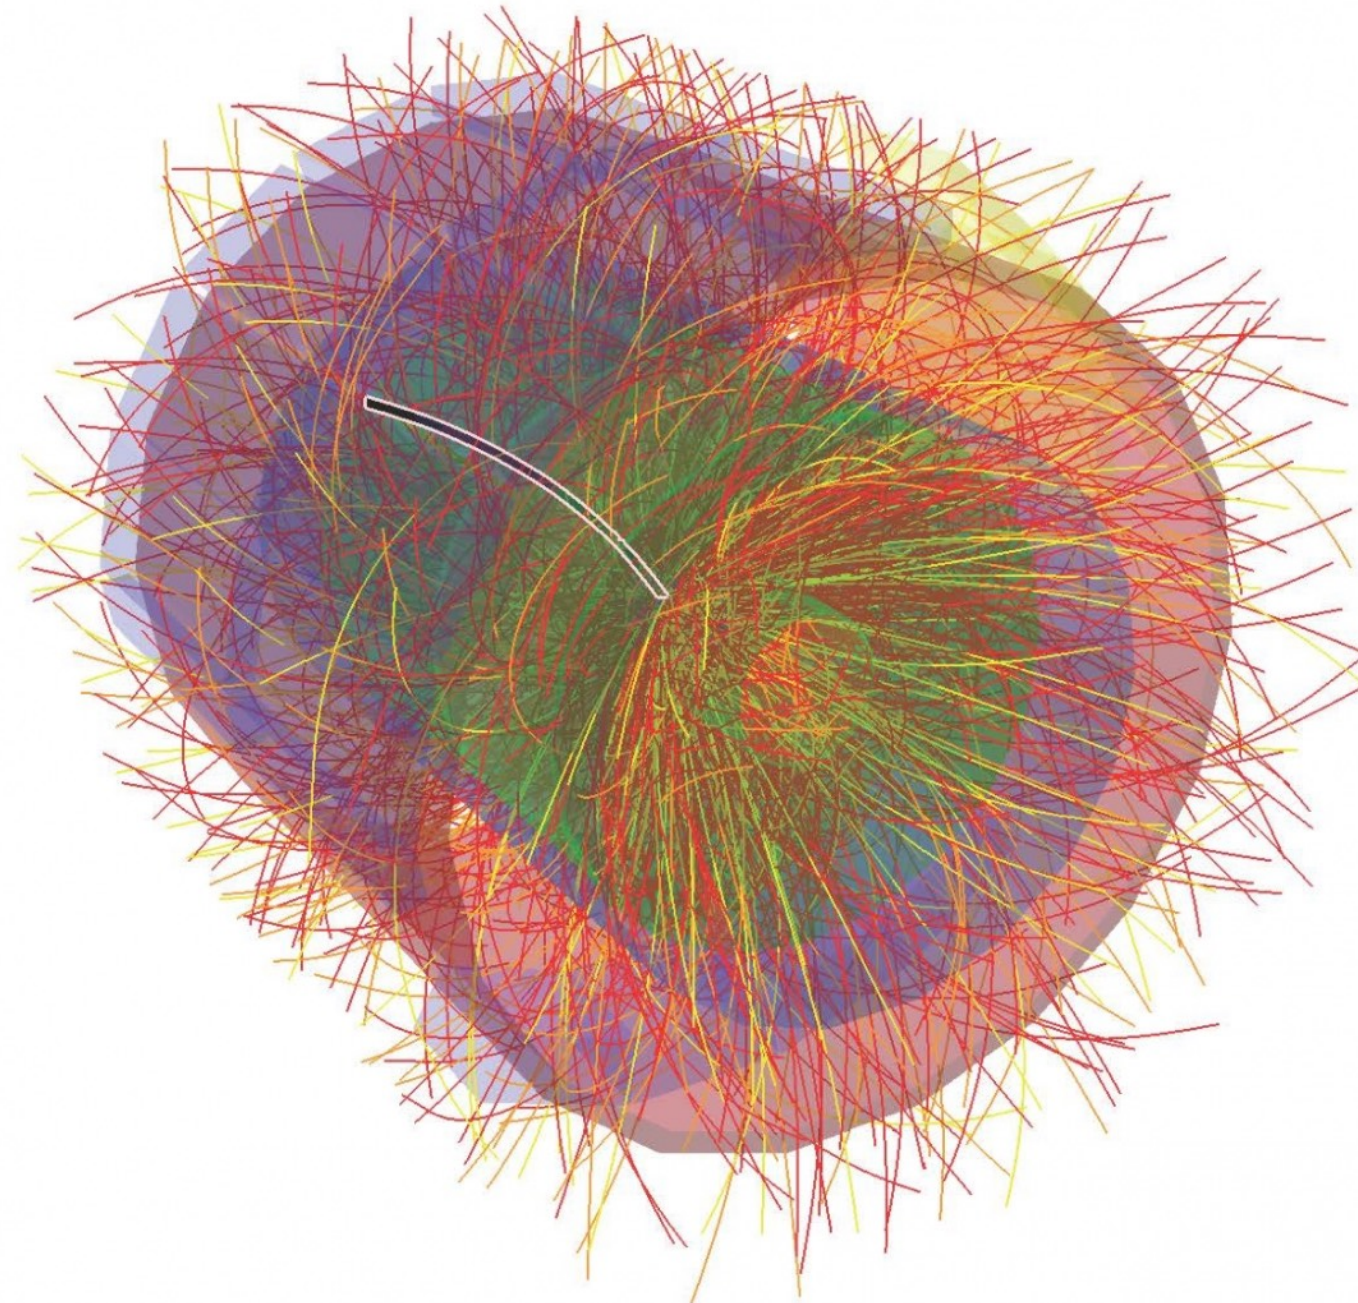

2. Sato, H. & Yazaki, K. *Phys. Lett. B* 98, 153–157 (1981)

# The heaviest stable anti-nucleus observed

Latest news

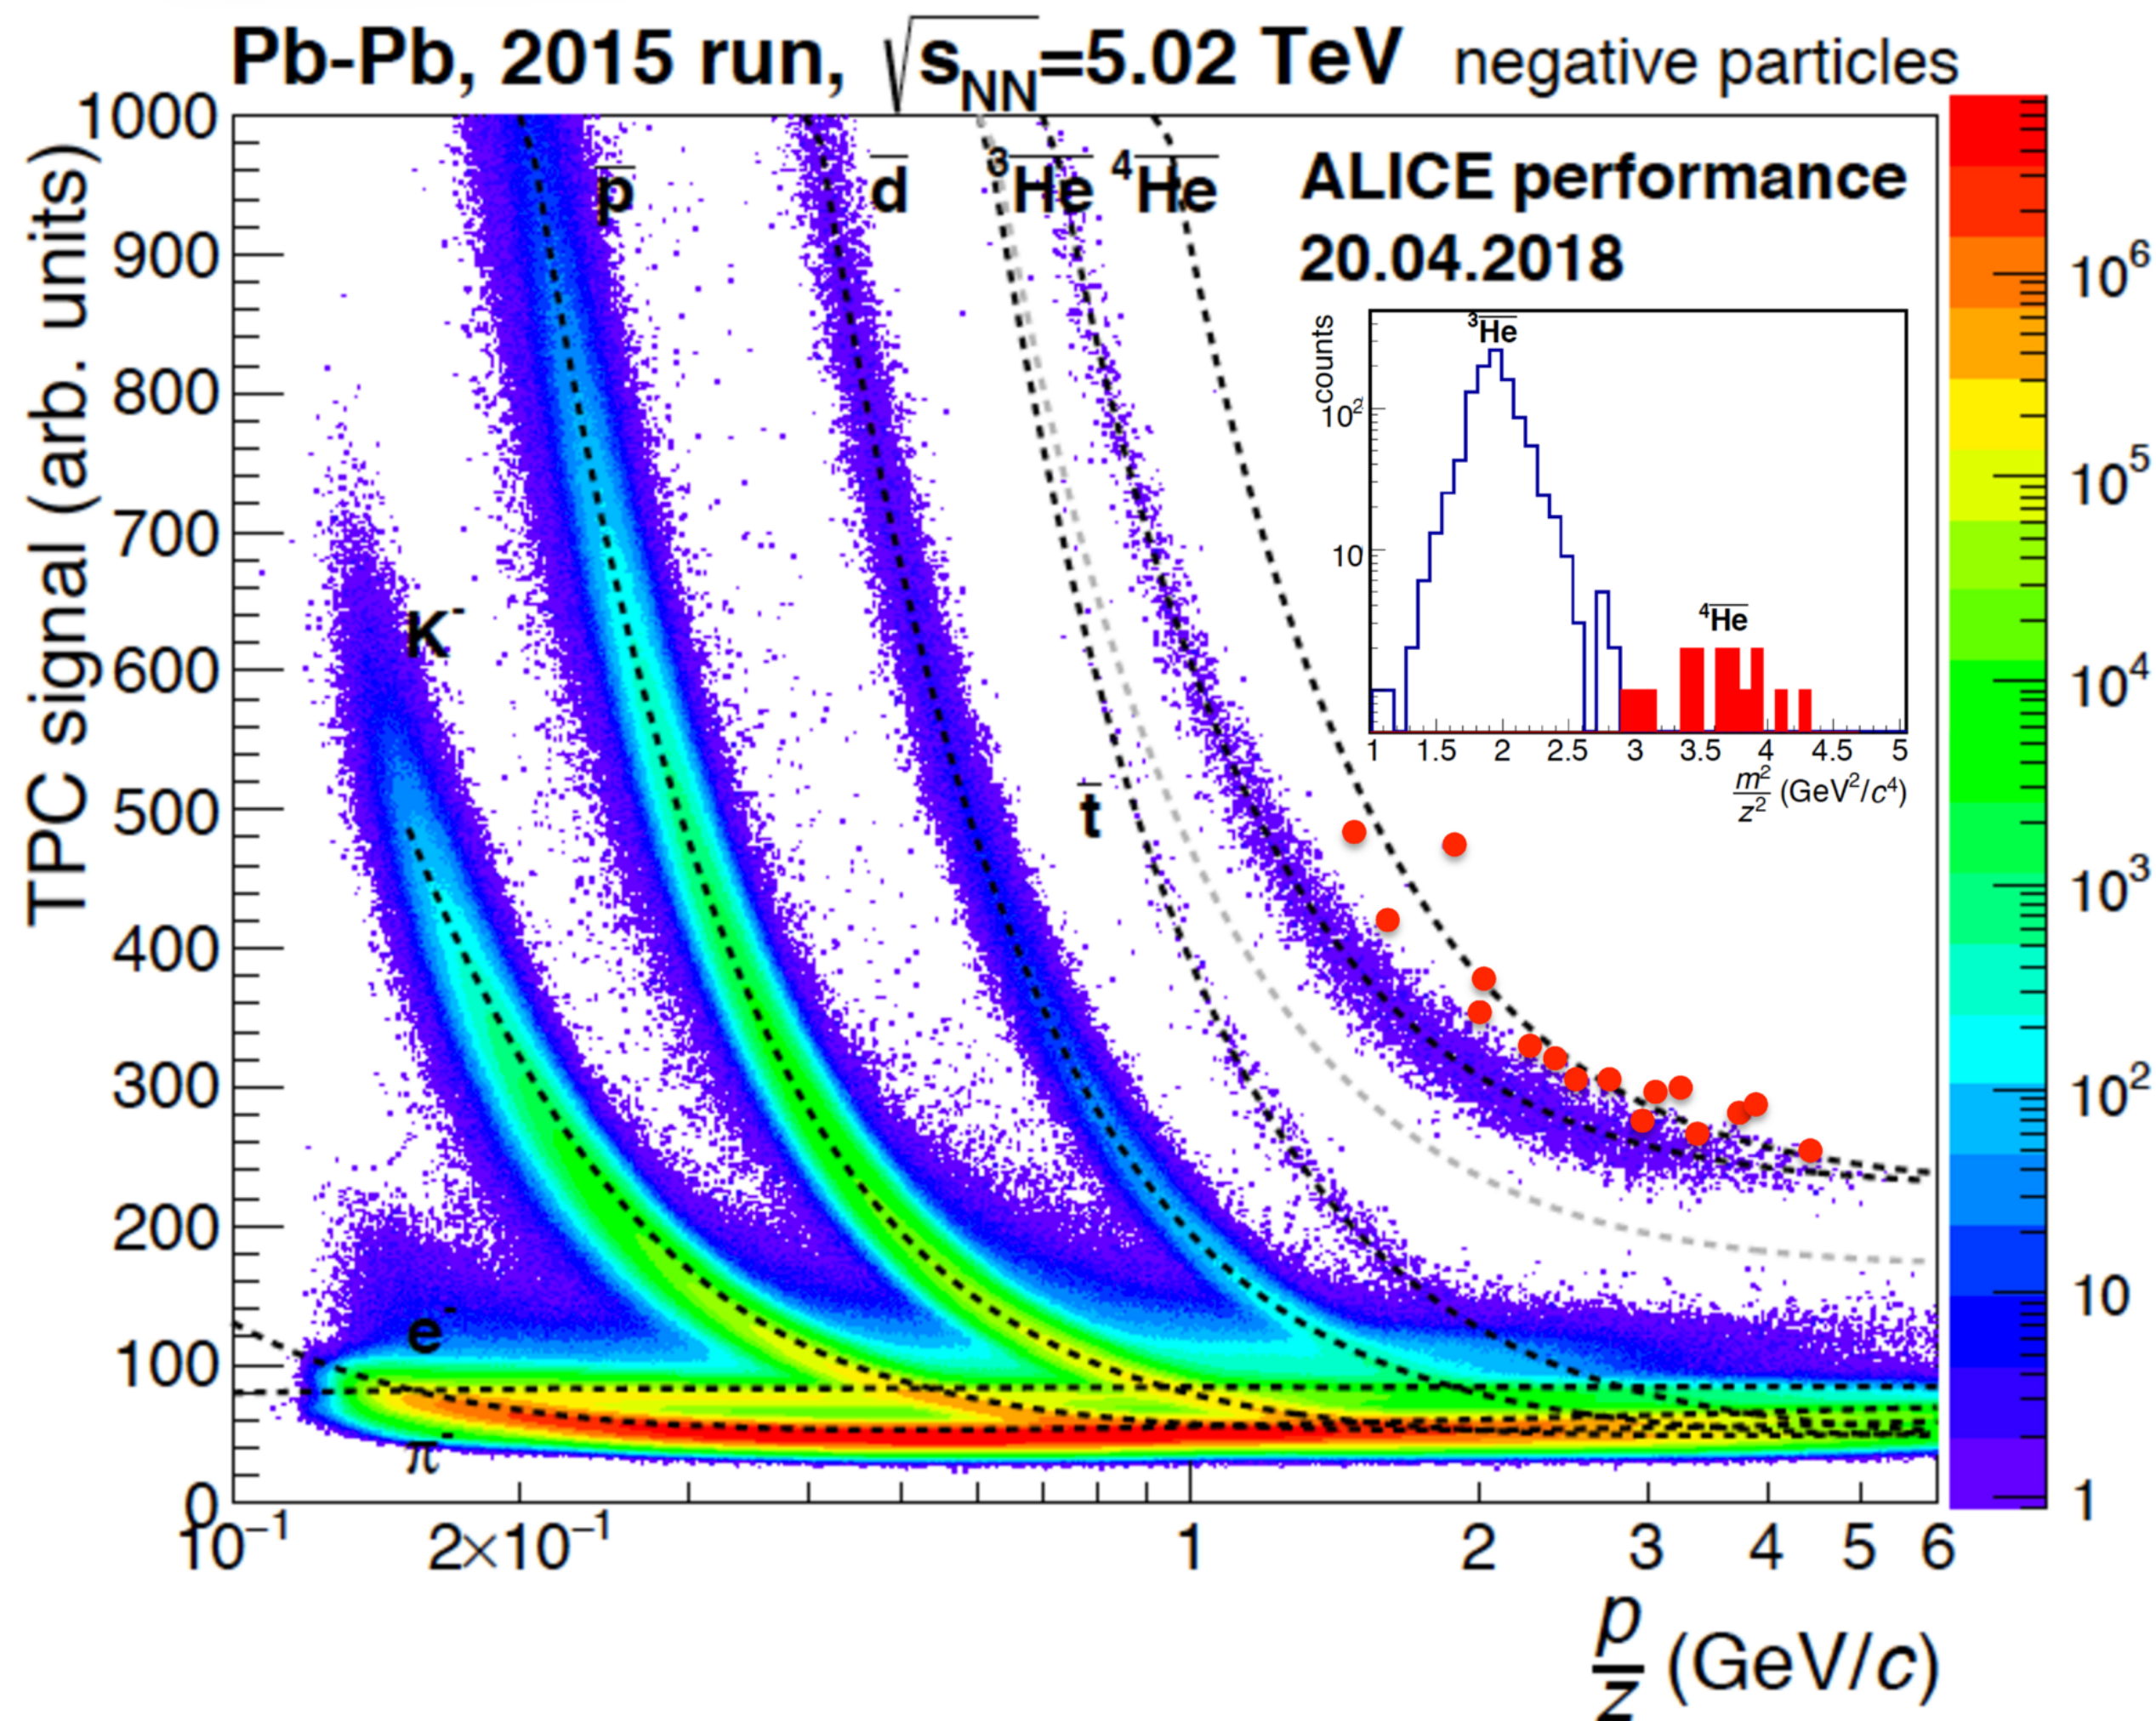

$^4\text{He}$  tracked in the ALICE detector

The ALICE Coll., Nucl. Phys, A 971, 1-20

The exponential decrease in nuclei production rate predicted by the Thermal model is confirmed

# The heaviest stable anti-nucleus observed

Performances for the  ${}^4\text{He}$  measurement using the new Pb-Pb dataset at 5.02 TeV look promising

What about adding the strangeness  
degree of freedom ?

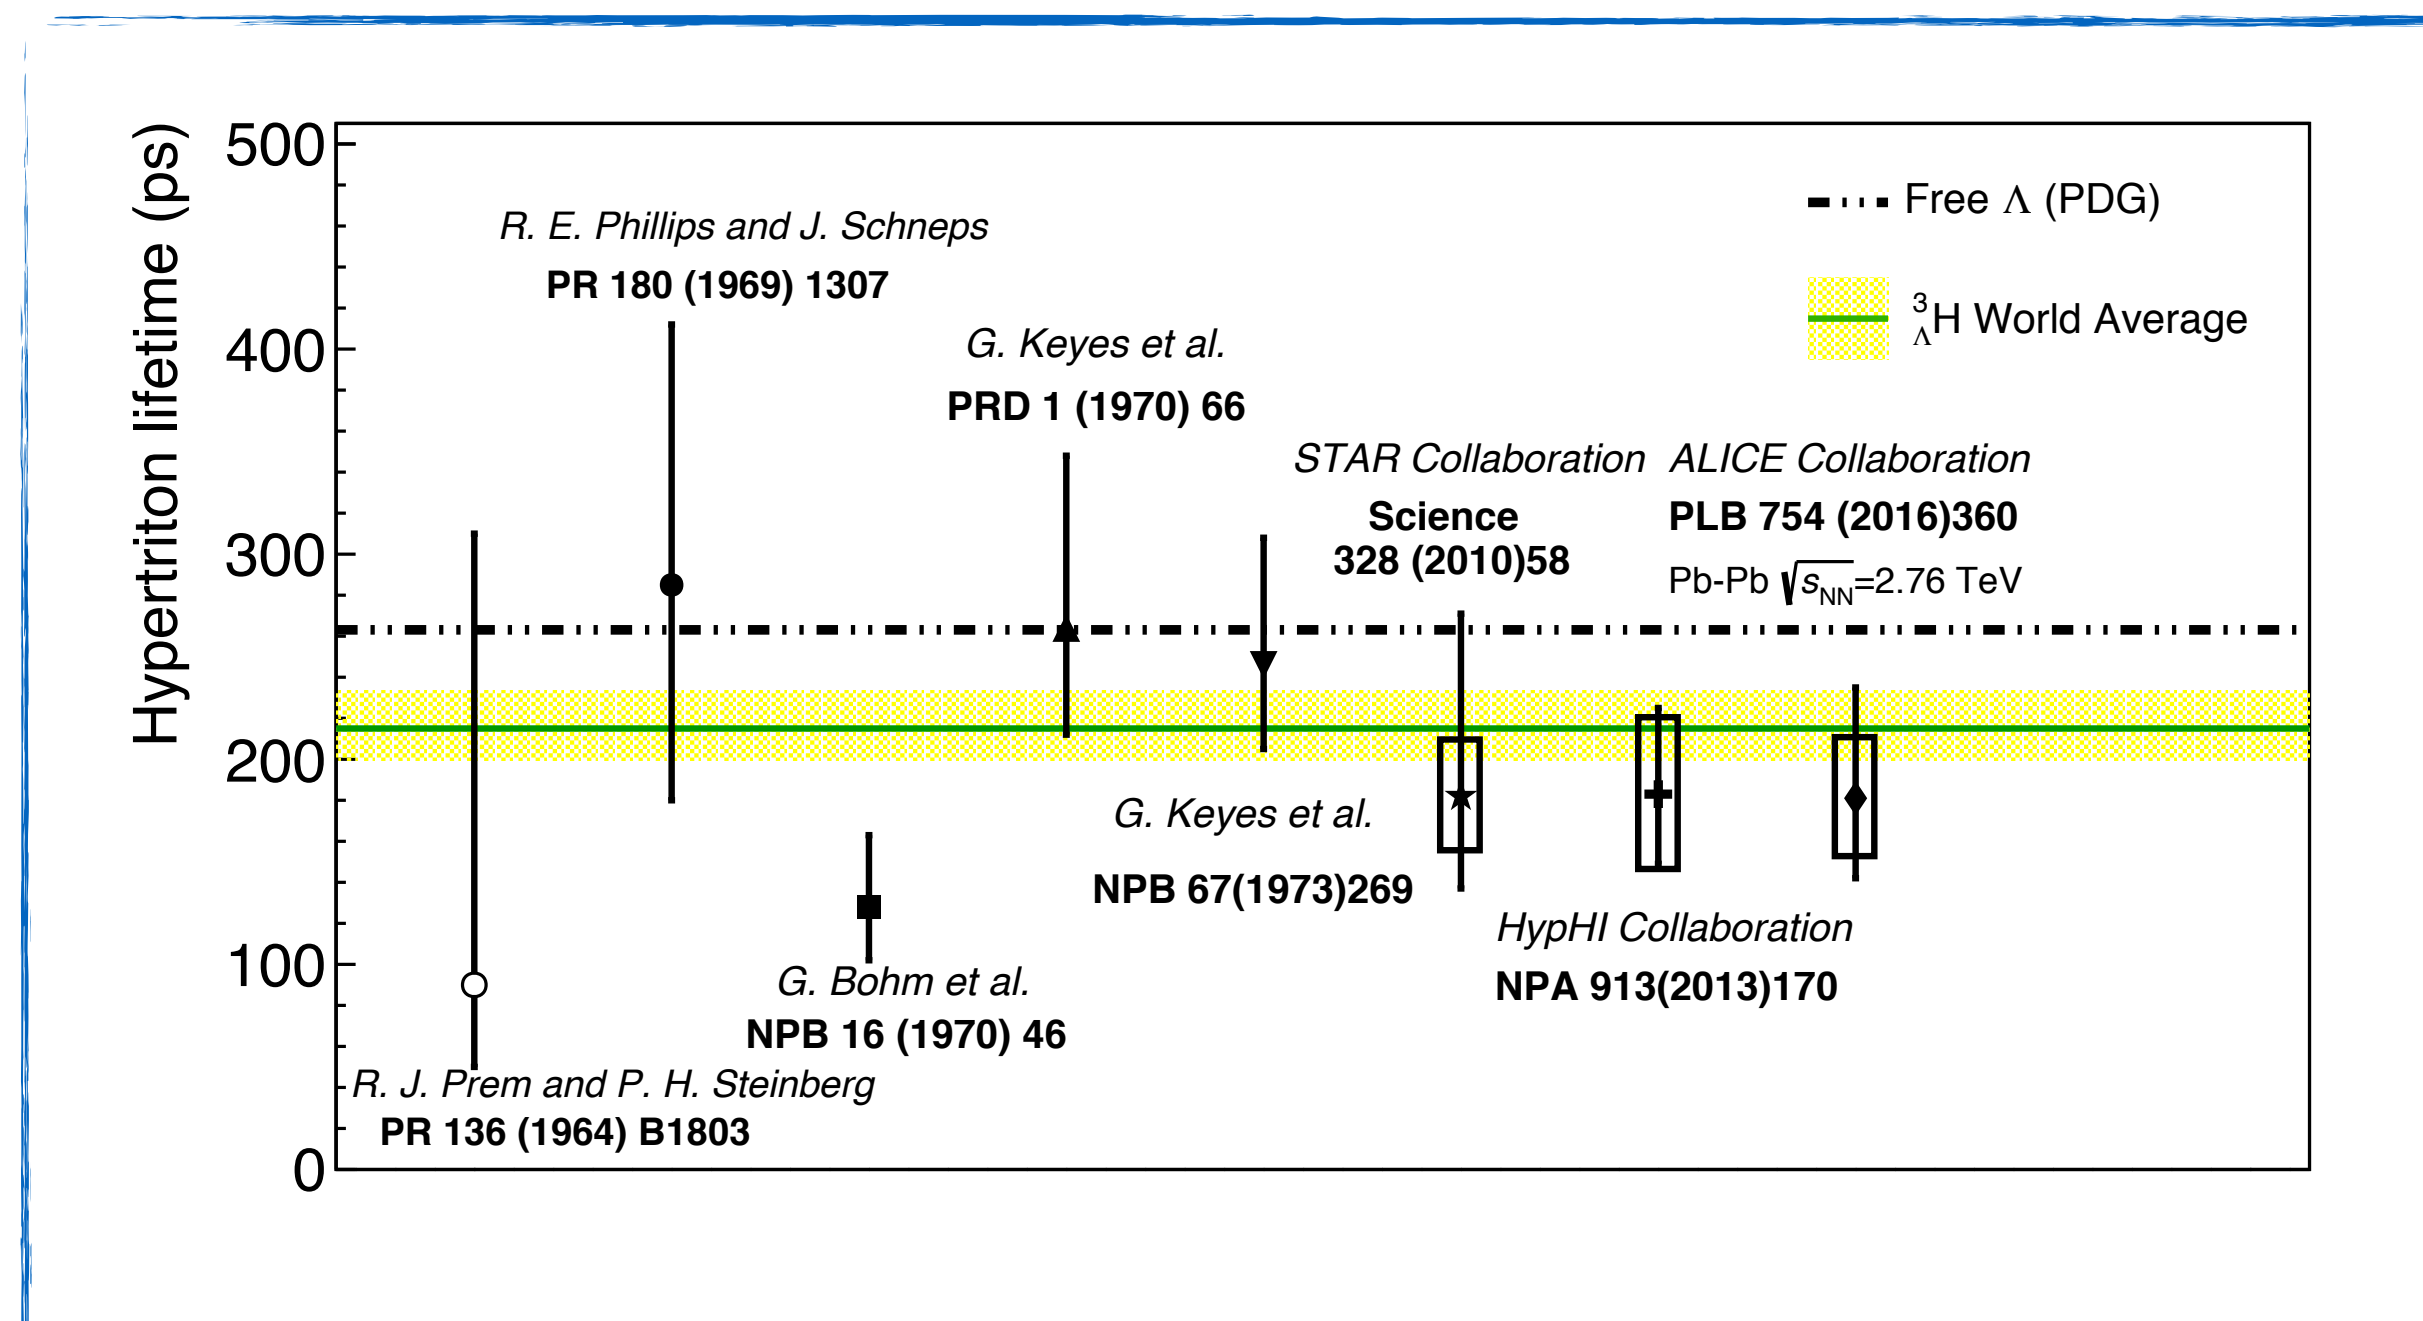

# The puzzle of hypertriton lifetime

## Hypertriton

- bound state of **p**, **n** and  **$\Lambda$** , is the lightest known hypernucleus
    - mass =  $2.99131 \pm 0.00005 \text{ GeV}/c^2$  [\*]
    - $\Lambda$  separation energy  $E_{B_\Lambda} = 0.13 \pm 0.05 \text{ MeV}$  [\*]
  - Very small  $E_{B_\Lambda}$  ( $\sim 130 \text{ keV}$ ) led to the hypothesis that the  ${}^3\text{H}$  lifetime is slightly below the free  $\Lambda$  lifetime ( $263.2 \pm 2 \text{ ps}$  [~])
  - Few theoretical predictions available
    - first one by Dalitz and Rayet (1966)
- $\tau$  range 239.3 - 255.5 ps
- by Congleton (1992) and Kamada (1998) → 232 ps and 256 ps

[\*] [D.H. Davis, Nucl. Phys. A 754 \(2005\) 3-13](#)

[~] [C.Patrignani et al. \(Particle Data Group\), Chin. Phys. C 40 100001 \(2016\)](#)

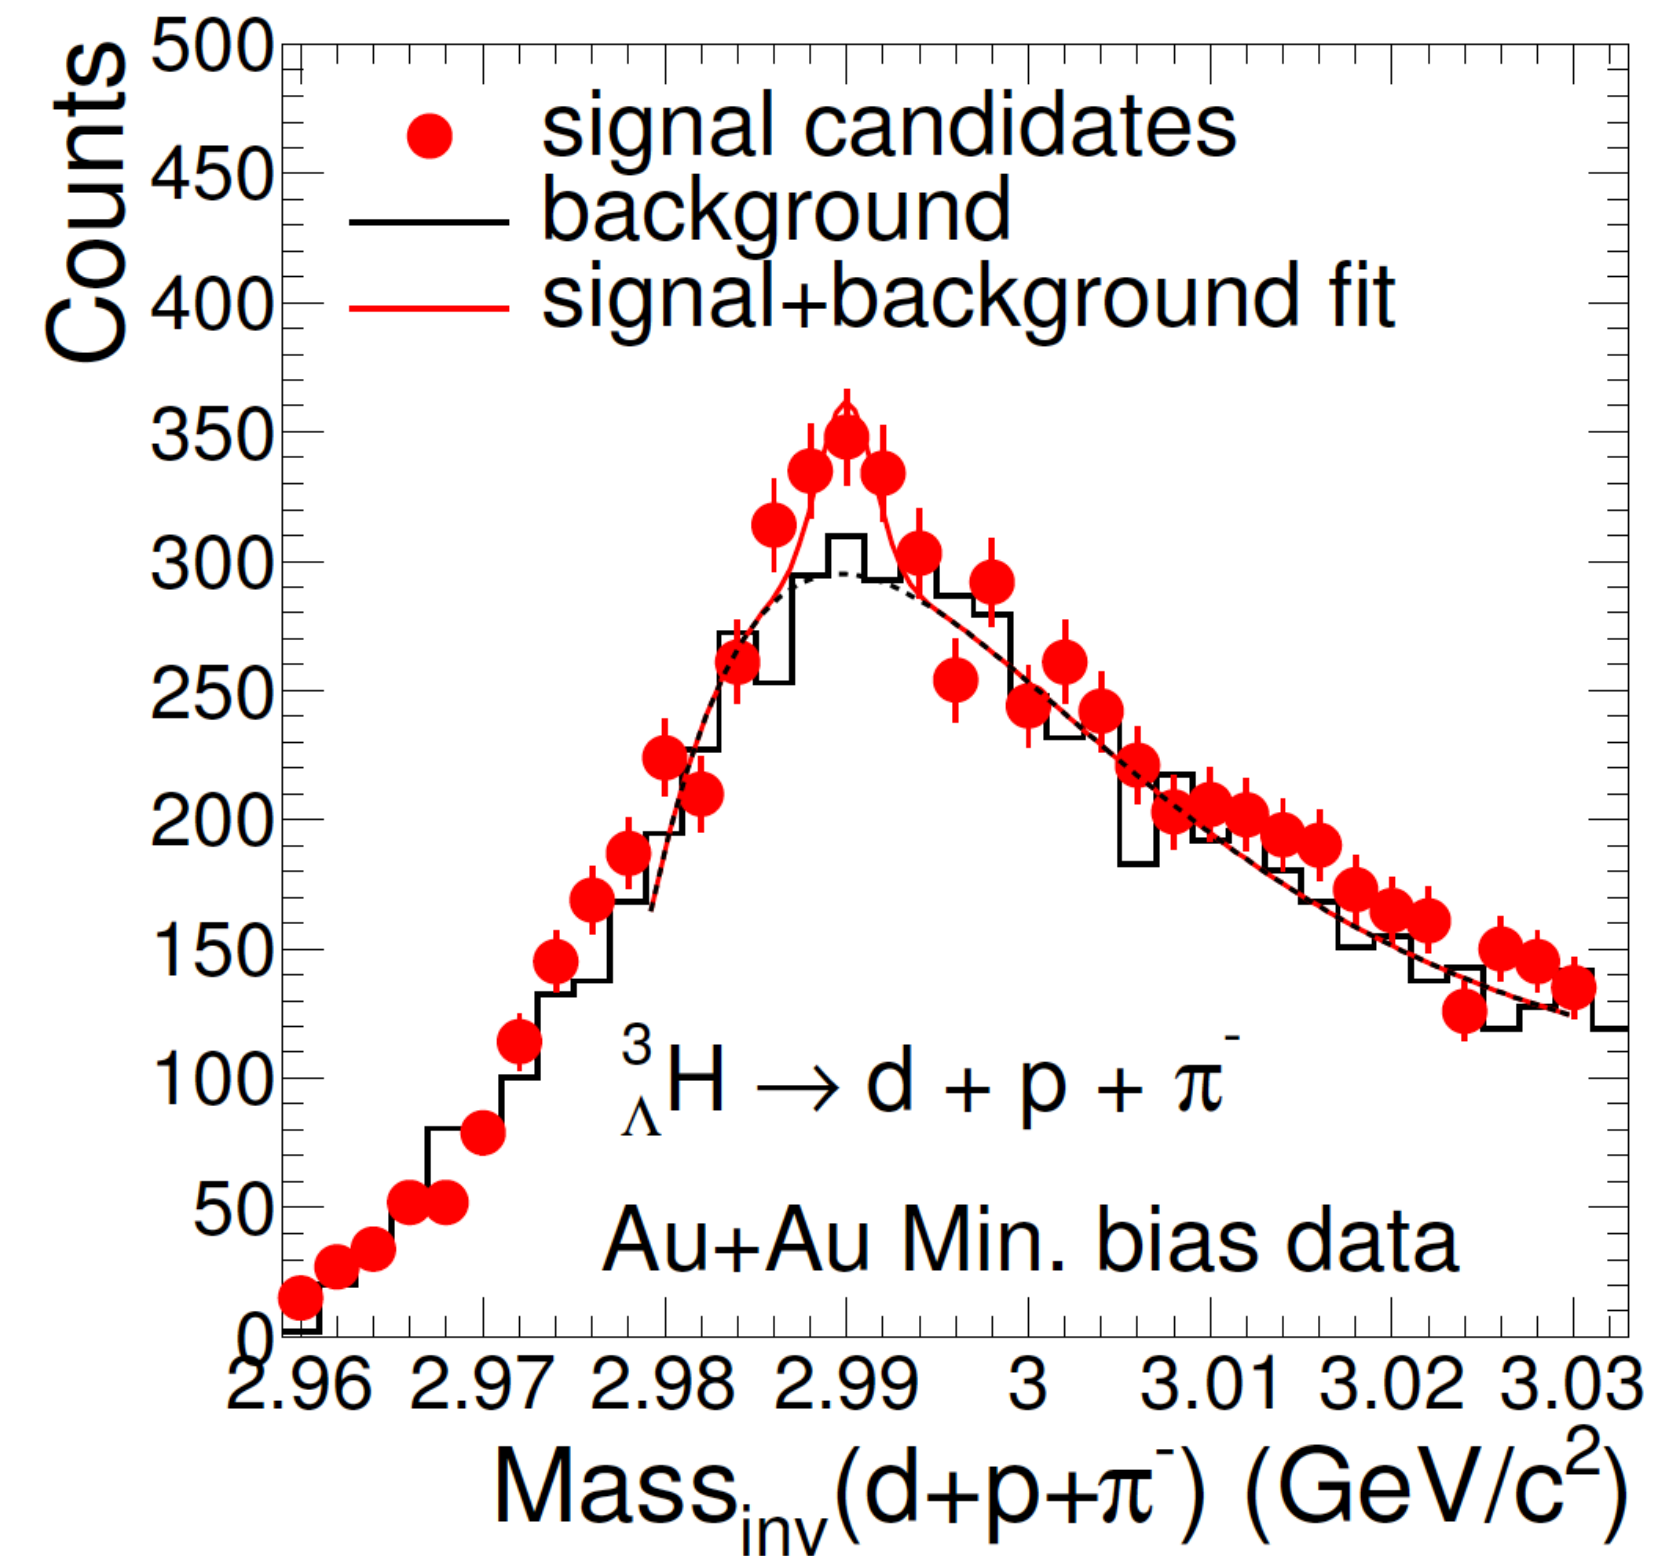

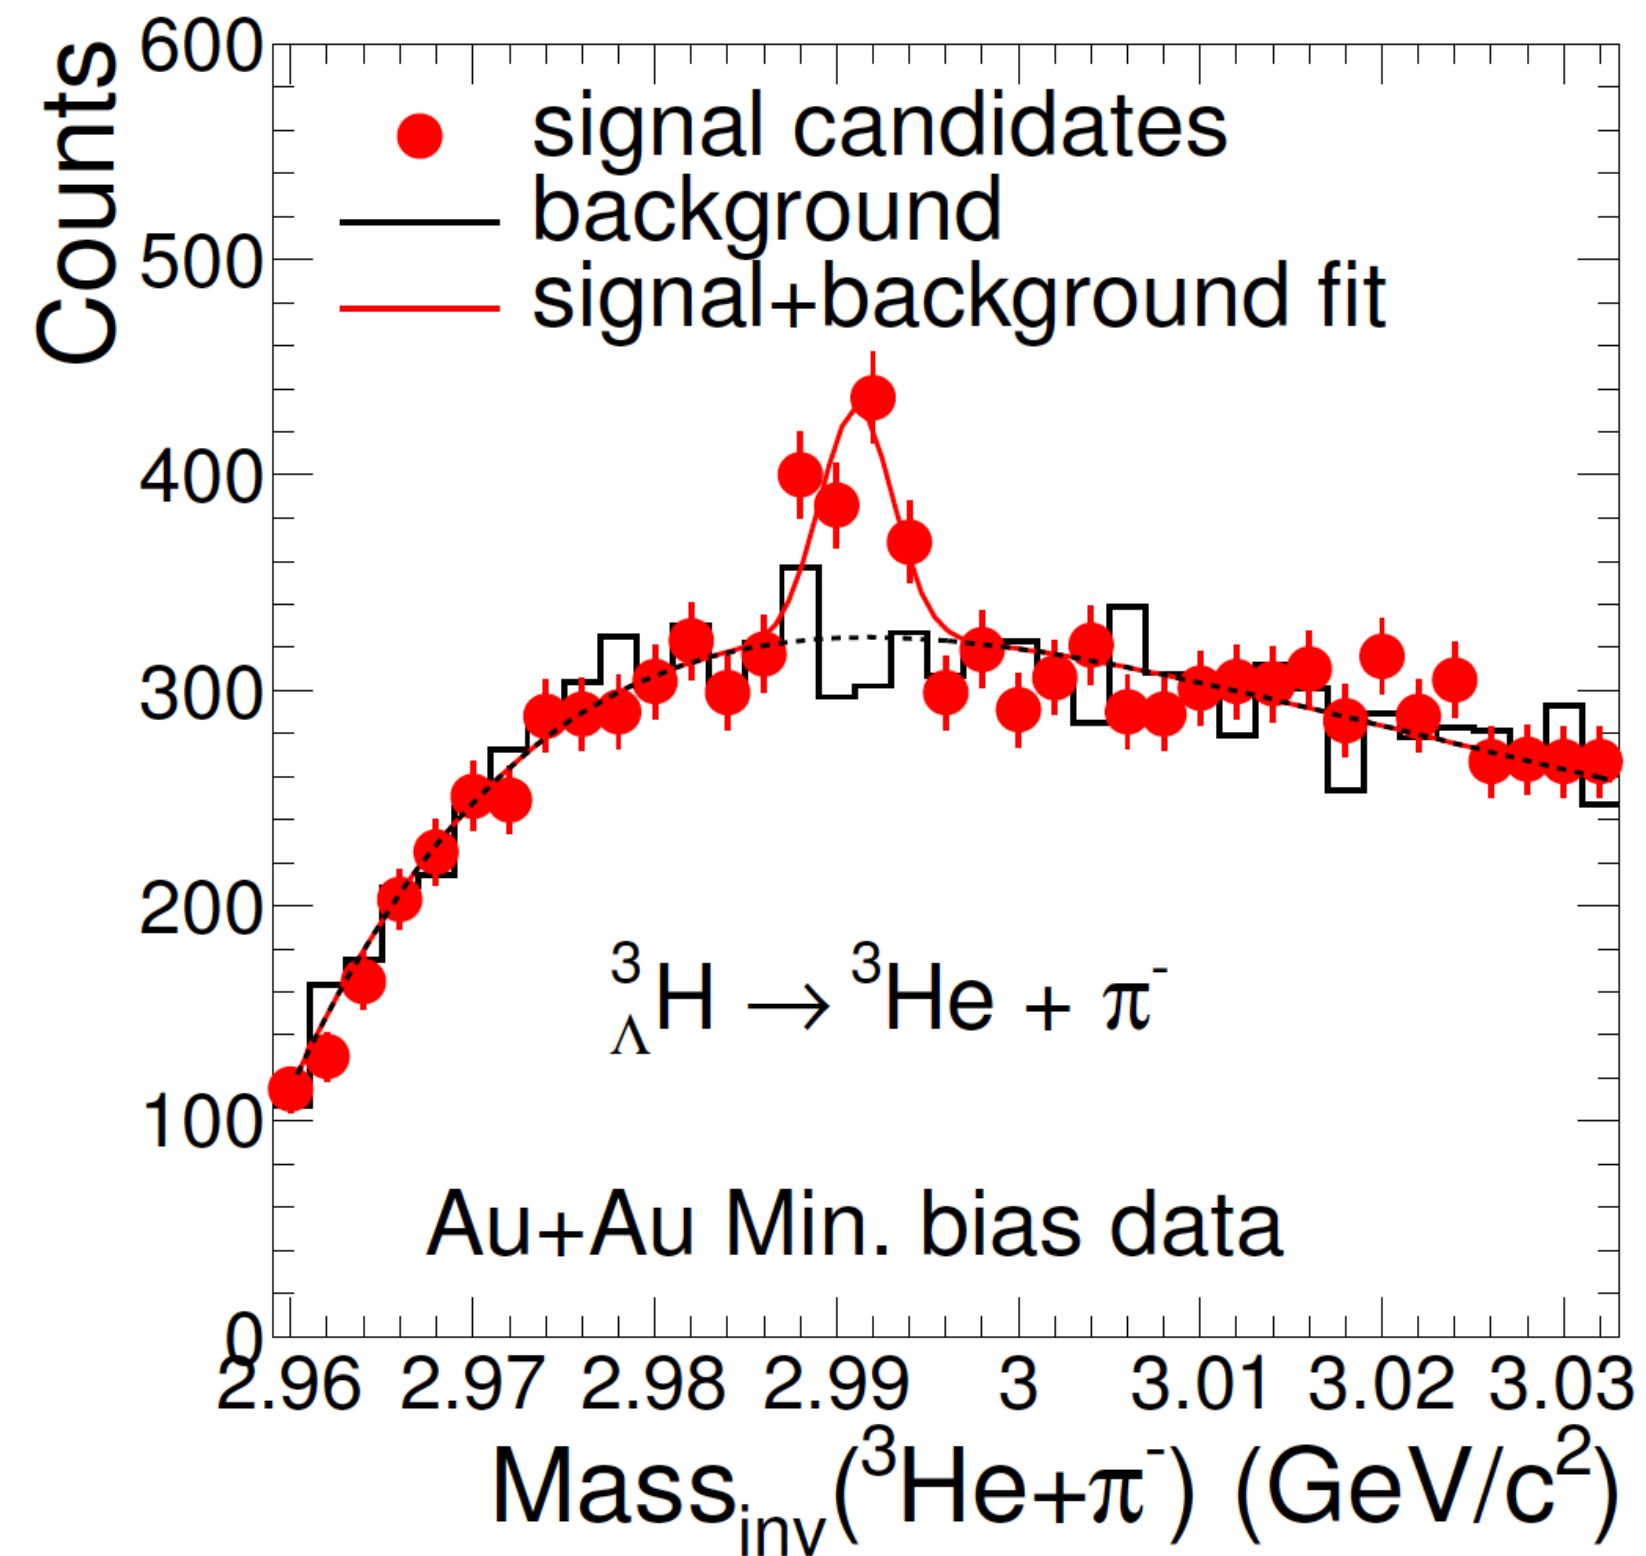

Re-evaluation of world average including ALICE result:  
 $\tau = (215^{+18}_{-16}) \text{ ps}$   
 ALICE value compatible with the computed average

# Hypertriton lifetime world data

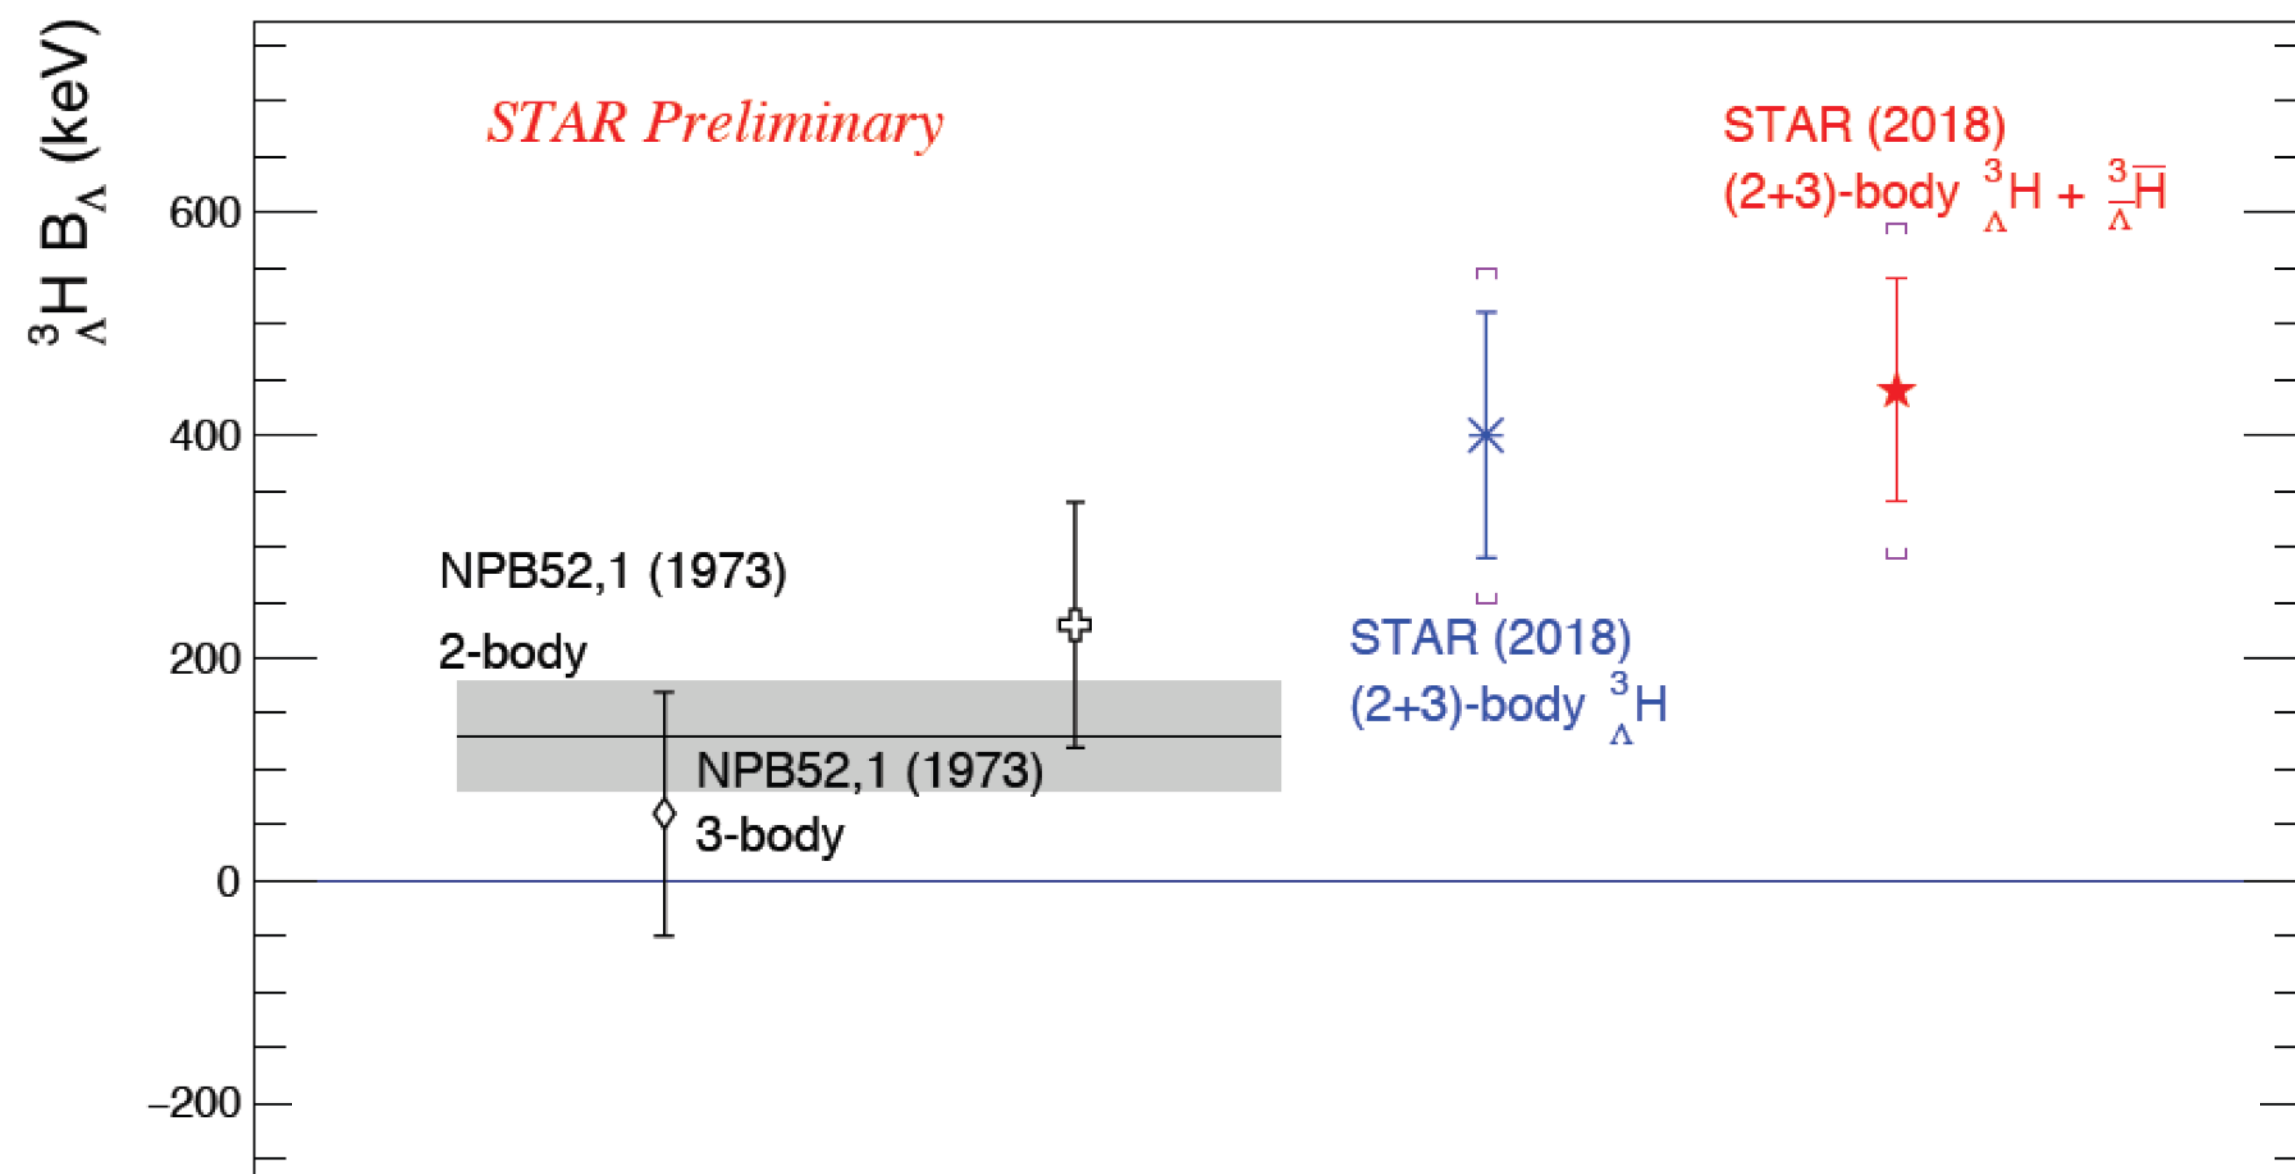

Latest news

- Previous heavy-ion experiment results show a trend well below the free  $\Lambda$  lifetime
- ALICE result from Pb-Pb at 5.02 TeV is closer to the free  $\Lambda$  and  $\sim 2\sigma$  higher than the latest STAR result (in terms of ALICE uncertainties)
- More precision, reducing the statistical uncertainties can be reached:
  - increasing the statistics
  - lifetime measured in the 3-body decay channel

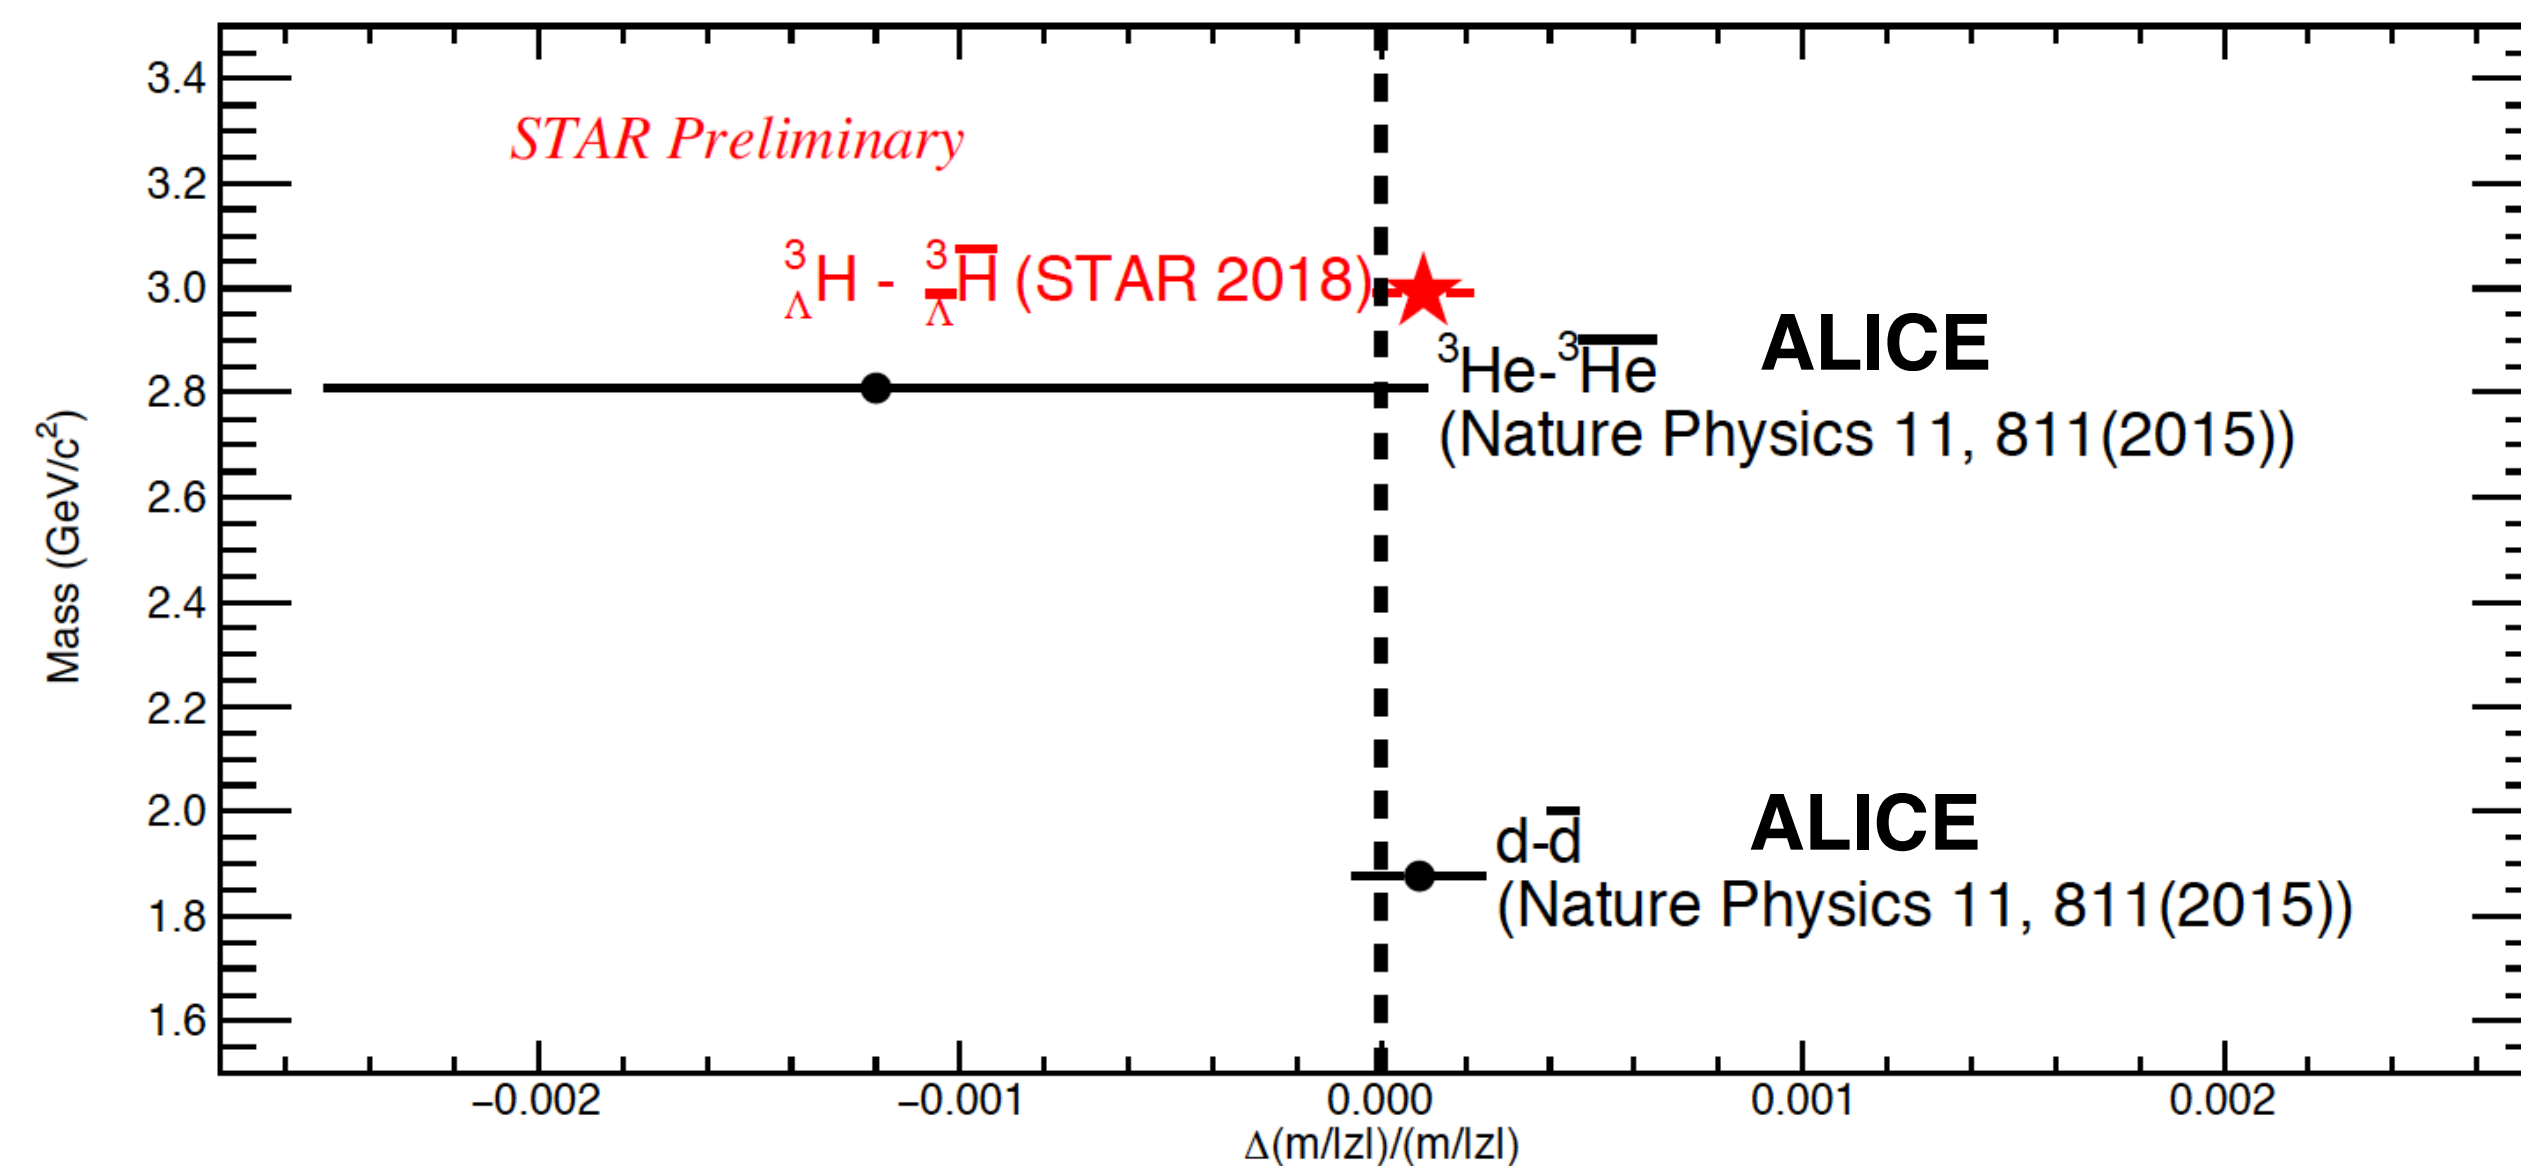

# Hypertriton: news from STAR

Latest news

Mean + stat. uncertainty only (NPB 52,1 (1973))  
 $0.13 \pm 0.05 \text{ (stat. only) MeV}$   
**STAR (2018):  $0.44 \pm 0.10 \text{ (stat.)} \pm 0.15 \text{ (syst.) MeV}$**

Mass difference measurement for hyper-matter confirms the result obtained with light nuclei and it is consistent with CPT prediction.

## Strangeness enhancement from pp to Pb-Pb collisions

- no energy and colliding system dependence: driven only by multiplicity?
- BES in different colliding system at RHIC would be beneficial
- What we need to change in microscopic models?

## (Anti-)nuclei production

- production in small system well reproduced by coalescence models
- thermal model prediction works nicely for heavy-ion results
- evolution of the results vs multiplicity: is there a common mechanism behind the production in different collisions system ?

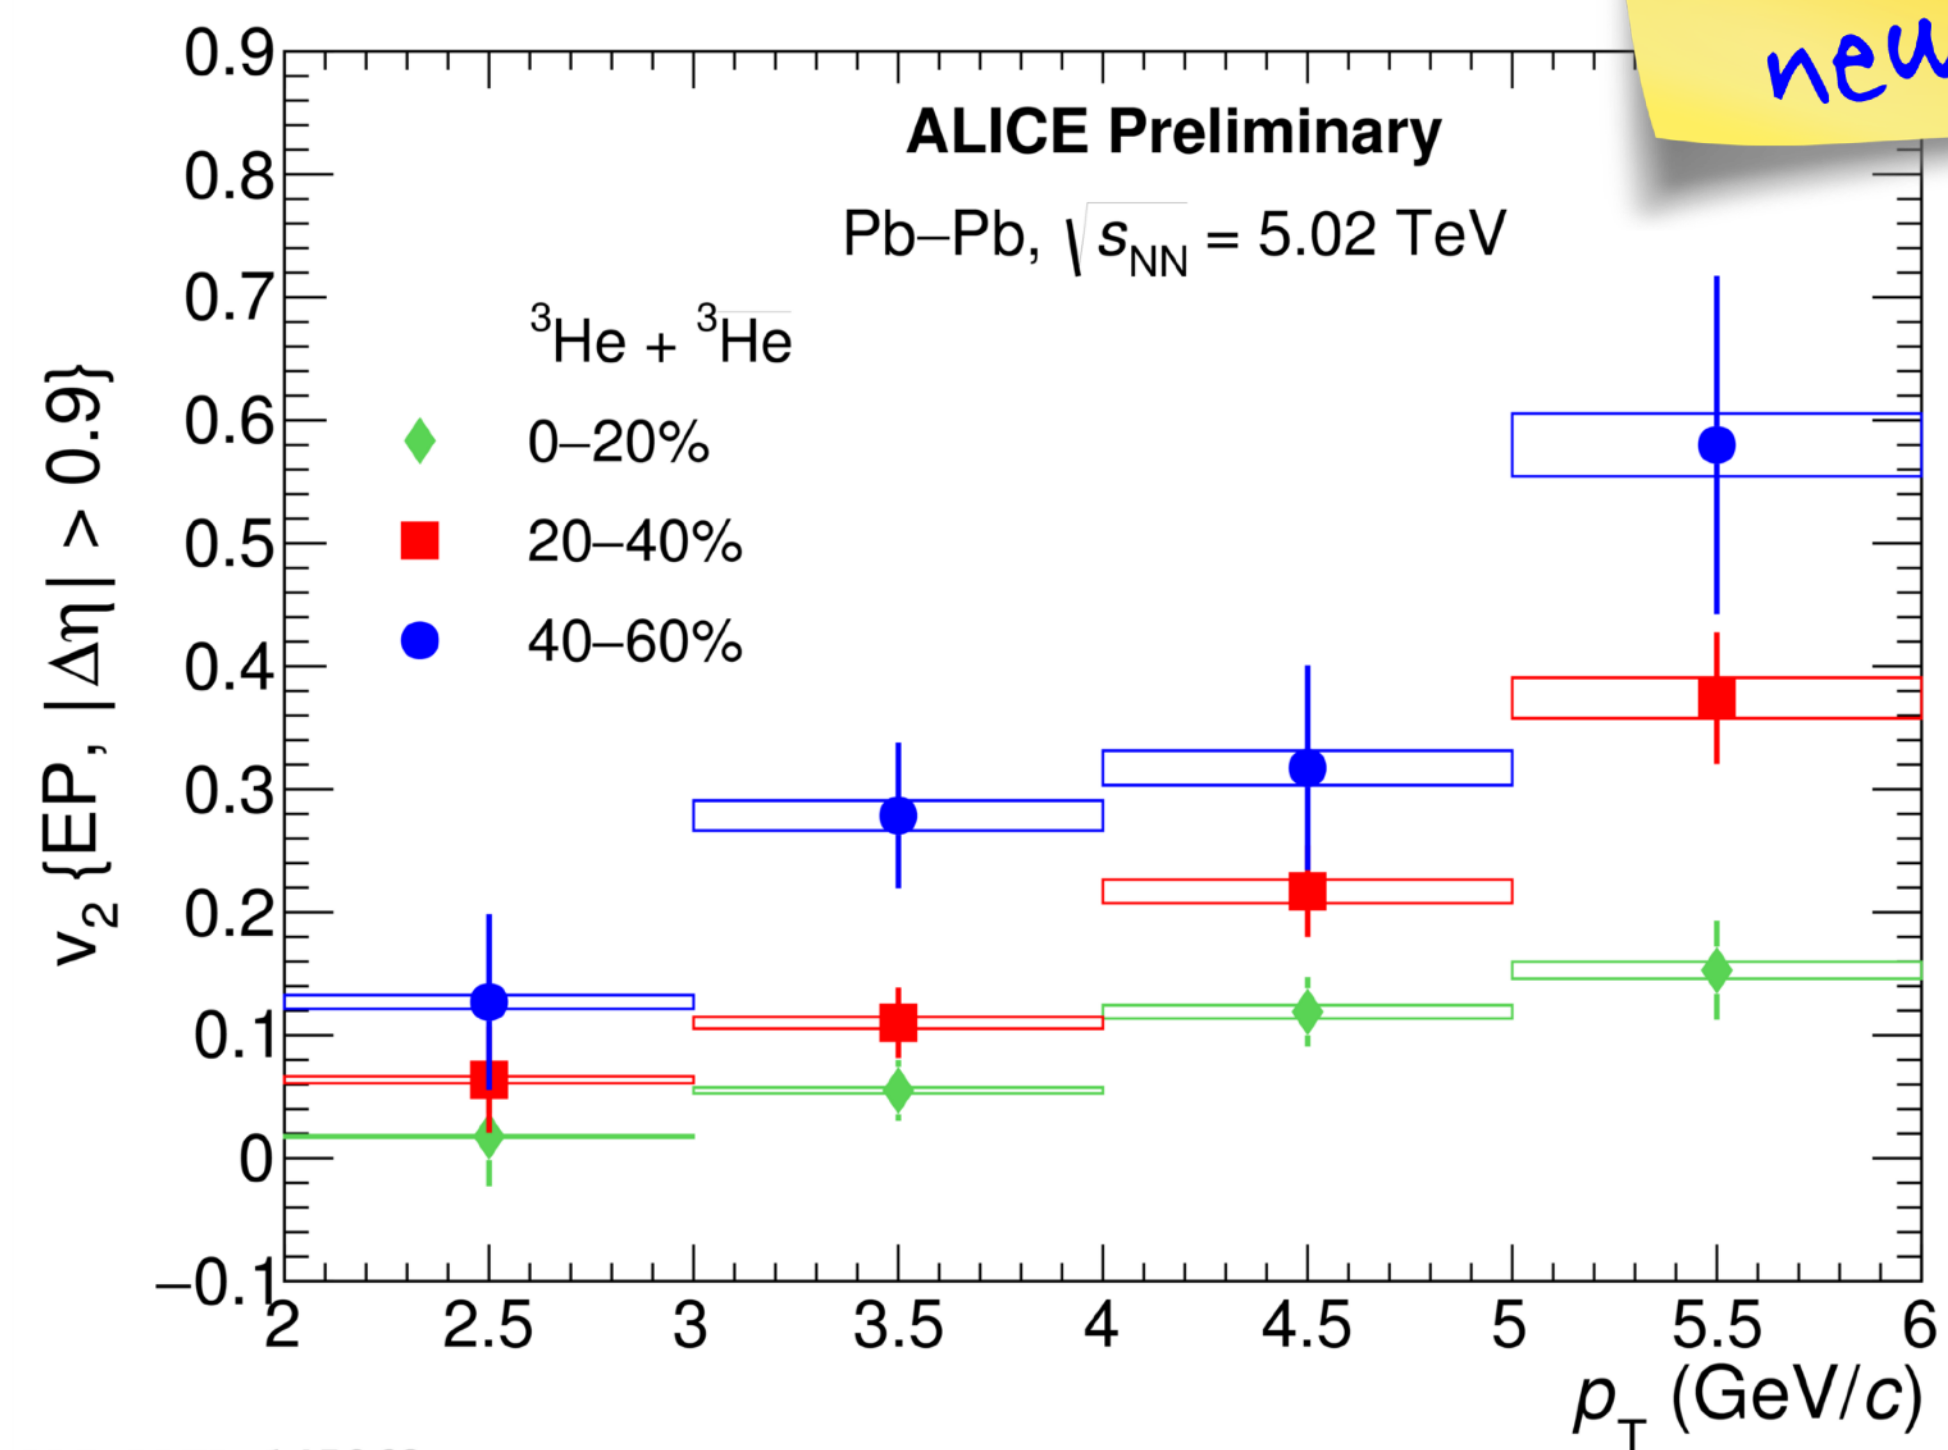

## (Anti-)hypernuclei production

- latest hypertriton lifetime from ALICE closer to the model prediction: more precision is needed to solve the existing puzzle
- hypermatter measurement as a test of CPT symmetry

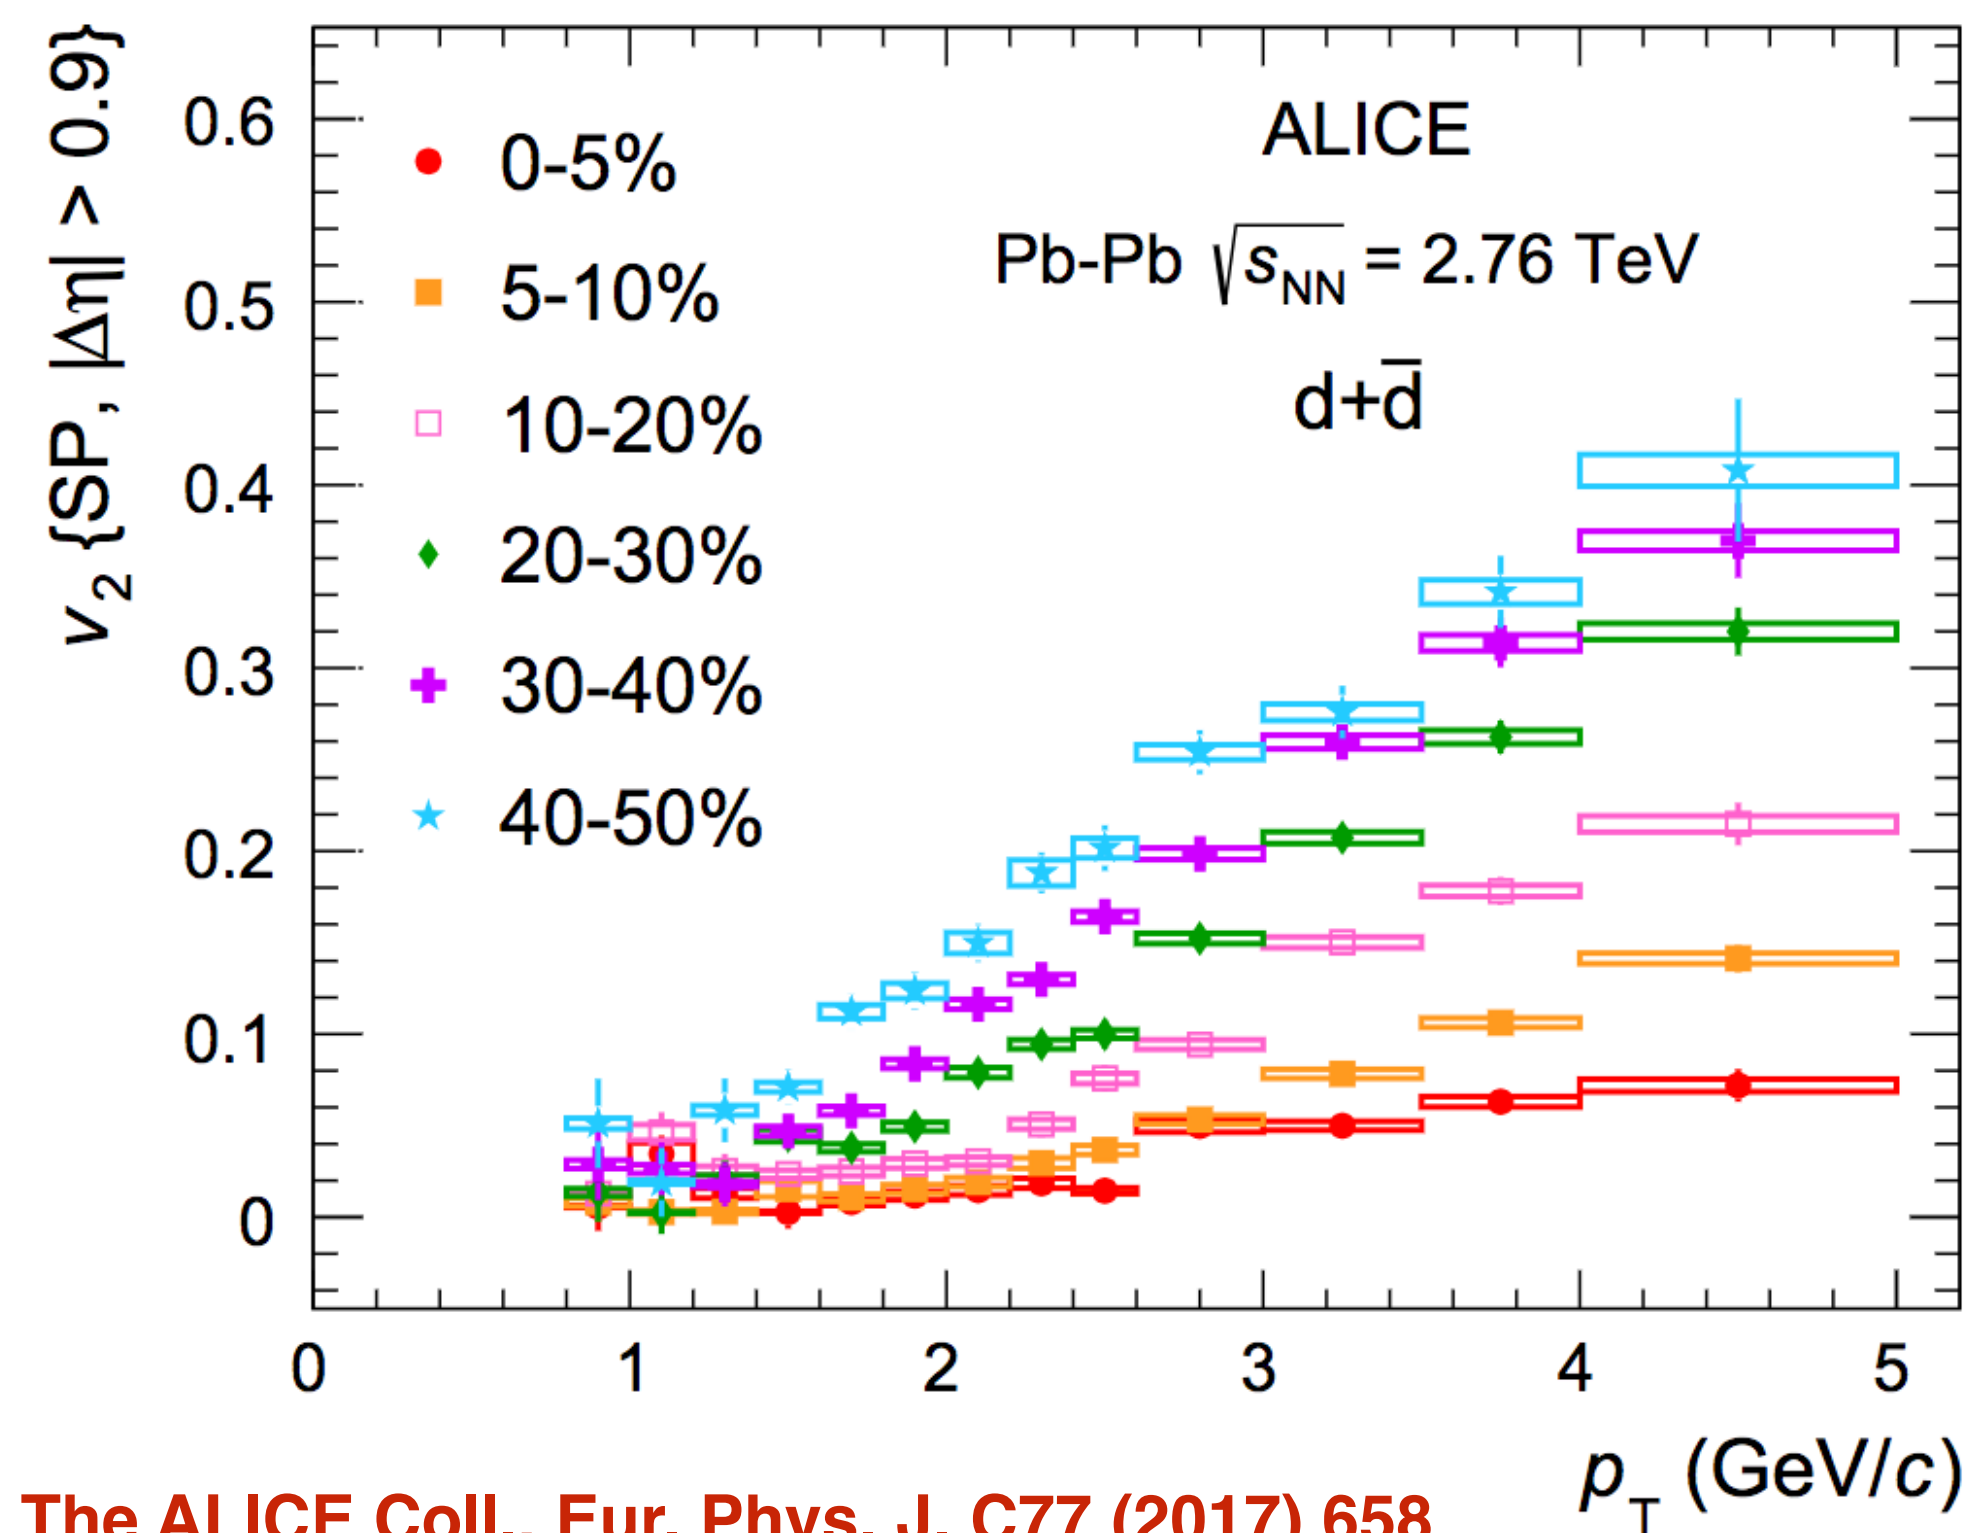

*Thank you!*
