NA62 Trigger and Data Acquisition system

Dario soldi on behalf on NA62 collaboration
NA62 aims to measure the ultra-rare decay $K^+ \rightarrow \pi^+ \nu \nu$
- The Standard model expectation is: $BR(\pi \nu \nu) = 8.4 \times 10^{-11}$

- very intense hadron beam particle rate
  - close to a GHz upstream
  - more than 13 MHz of particles downstream

- good time resolution at level-0;
- a fast, selective trigger and data acquisition system;
- minimization of data-collection dead times and maximization of its efficiency and reliability rank high among the required features.
GENERAL NA62 TRIGGER OVERVIEW

- 3 trigger levels:
  - hardware level: **level-0 trigger**
  - software level on partial data: **level-1 trigger**
  - software level on complete event: **level-2 trigger**

- Level - 0 trigger:
  - No collisions but continuous stream of data:
    - An Event is defined by in-time local conditions of different detectors.
    - Requires a seed detector to define a reference time.

Reference Time

coincidence window
The NA62 Experiment

Ideas are everywhere, but the knowledge is rare

Thomas Sowell
THE NA62 EXPERIMENT

- Fixed Target experiment: 75 GeV secondary beam (6% kaons);
- High intensity beam: ~750 MHz;
- Signal: 1 beam track, 1 charged track, nothing else;
- Kinematics: $O(10^4)$ background suppression;
- Downstream $\pi/\mu/e$ separation;
- $10^7$ muon suppression, mainly from $K \rightarrow \mu\nu$;
- $10^7$ photon (mainly from $K^+ \rightarrow \pi^+\pi^0$) suppression;
- Sub ns time resolution.

...and many others
Kaon Tag (KTAG):
- Differential Cherenkov detector selecting Kaons;
- ~80 ps time precision;
- KTAG participates at level-1 trigger selection.

Beam Spectrometer (GigaTracker - GTK):
- 3 stations of Silicon pixel detectors inside an achromat;
- Time: \( \sigma \approx 130 \text{ ps per station}; \)
- Direction: \( \sigma_{dx,dy} \approx 0.016 \text{ mrad}, \text{ Momentum: } \Delta P/P < 0.4\%; \)
**Straw Spectrometer:**
- 4 straw chambers in vacuum;
- Each chamber measuring 4 coordinates (views);
- High accuracy: 130 μm/view;
- Straws participate to level-1 trigger selection.

**RICH:**
- Cherenkov detector filled with Neon;
- 70 ps of time resolution.
- Used in the level-0 trigger as time reference.
- GPU-level-0 trigger implementation under study.

**NA48 CHOD**
- Plastic scintillator hodoscope;
- ~200 ps time resolution;
- Used in level-0 trigger as control trigger;

**CHOD:**
- Plastic tile scintillator;
- <1 ns time resolution;
- Decay topology detection;
- Used in level-0 trigger;
Large Angle Vetoes (LAV):
- 8.5 – 50 mrad
- 12 stations along the vacuum tank;
- LAV12 can be used in level-0 trigger to veto photons;
- LAVs participate at the level-1 trigger selection.

Liquid Krypton Calorimeter (LKr):
- Electromagnetic calorimeter
- photon veto coverage 1÷8.5 mrad;
- LKr is used in level-0 trigger to veto photons, mostly from $\pi^0$s.

Small Angle Vetoes (SAV):
very small angle <1 mrad;
THE NA62 EXPERIMENT

Muon Vetoes

- **MUV1/MUV2: Hadronic Calorimeters**;
  - Readout with LKr electronics;
  - Can be used in level-0 as hadron trigger to complete the LKr-electromagnetic calorimeter information;

- **MUV3: Muon Veto**
  - Placed after an iron wall;
  - Rate: ~ 14 MHz muons.
  - Used in level-0 trigger to veto muons;
NA62 Data acquisition system

If we have data, let's look at data. If all we have are opinions, let's go with mine.

Jim Barksdale
THE NA62 DATA ACQUISITION SYSTEM

- Fixed target experiment: bursts ~3 seconds long;
- Some detectors send raw data (primitives) to the level-0 trigger processor L0TP;
  - Primitives are generated from TEL62 read out boards.
- L0 trigger is generated after a maximum latency of 1 ms;
- All detectors except Calorimeters and GTK respond to L0;
- Calorimeters and GTK send data after L1 request;
- L2 trigger run over the complete event information.

burst length: ~ 3 sec
protons on target: $3.3 \times 10^{12}$
Secondary beam: 750 MHz
L0 input: >10 MHz
L0 output: 1 MHz
L1 output: 100 kHz
L2 output: 10 kHz
Data Format: 32 bit.

Primitive ID: encodes the detector information (Energy, multiplicity, position);

Timestamp: 25 ns precision time of the raw data;

Fine Time: additional time information with a precision up to 100 ps.
TEL62 - A COMMON READOUT

- Allow to read data and generate trigger primitives;
- Upgrade of LHCb TELL1;
- Hosts TDC Boards: custom mezzanine equipped with 4 High Performance Time to Digital Converter chips with **100 ps LSB precision**.
- 4 FPGAs (PP) are connected to TDC Boards and to 2-GByte DDR2 memory buffers, storing the data during the L0 trigger latency.
- The central FPGA (SL): connected with each PP through two 32-bit data buses reserved for data and L0 trigger primitive flow.
- The data and L0 trigger primitives from all PP are linked, *possibly zero suppressed* and encapsulated on the SL, where aggregation with data from other TEL62 boards can also take place.
- Data from several events are packed together, stored in a Quad Data Rate (QDR) SRAM, and finally sent to the output board.

[Diagram of TEL62 architecture]

Dario Soldi - NA62 Trigger and Data Acquisition
L0 - Trigger Generators

Tank: So what do you need? Besides a miracle?
Neo: Guns. Lots of guns!
Matrix
What we need:

- Charged Track Topology, Multiplicity and Time
  - CHOD hodoscope
  - RICH

- Energy
  - Calorimeters

- Vetoes
  - Calorimeters
  - LAVs
  - Muon Veto (MUV3)

- Minimum Bias Trigger: NA48-CHOD

- R&D: RICH GPU Trigger Generator
CHOD - MUV3 L0 TRIGGER GENERATORS

- **MUV3** is used in L0 trigger to tag muons;
  - **14 MHz** of muon rate;
- **CHOD** is used to tag any charged particle;
  - identify different topologies;

✧ TDC hits are read from the PP-FPGA, **arranged and time-ordered to the level of 25 ns**;
✧ TDC hits are sent to one of 64 tile modules;
✧ Tile modules contains 2 buffers used to store hits from the two channels of the same tile, plus a **coincidence module that compares absolute hit times**;
✧ If hits are within coincidence time window they are combined into a **tight candidate**, otherwise the earlier hit is converted to a **loose candidate**, while the later one remains in the buffer;
✧ An output module transfers candidates to the SL-FPGA in frames of 6.4us;
✧ A **sorting module** contains two sets of 64 sorting buffer FIFOs;
✧ Candidates in consecutive frames are sent alternately to the first or second buffer set
✧ each buffer stores hits related to a **100 ns time interval**, with earliest hits in the first and latest hits in the last buffer.
✧ Once all candidates from a frame have been written, they are passed to the **clustering modules**.
A cluster is characterized by:

- the cluster **seed time** \((T)\) being the time of the candidate that created the cluster;
- the **summed time-difference** \((DT)\) between the merged candidates and the cluster seed time;
- the **number of candidates** \((N)\) merged into the cluster;
- **Four flags to record which quadrants** the merged candidates are assigned to.

Candidates are read, compared to the cluster seed time. If their time is within a matching time window around the seed time, they are merged into the cluster. Otherwise, the candidate is converted into a new cluster.

Clusters are converted to trigger primitives labeled with an absolute primitive time

\[
PT = T + \frac{DT}{N}
\]

NA62 MUV3 M1

Efficiency vs. Track momentum (GeV/c)

$\Delta T$ MUV3 Primitive - MUV3 Hits
Online multiplicity counts with respect to the offline reconstruction

Primitive time resolution with respect to the time hits

\[ \sigma \sim 280 \text{ ps} \]
THE NA62 LKr ELECTROMAGNETIC CALORIMETER

- Radiation Length: 27 X0;
- Read out channels: 13248

- $\sigma_{E/E} (GeV): 0.032/\sqrt{E} + 0.09/E + 0.0042$;
- $\sigma_{x,y/x,y} (cm): 0.42/\sqrt{E} + 0.06$;
- $\sigma_{t/t} (ns): 2.5/\sqrt{E}$;

- Photon veto in the angular decay region 1- 8.5 mrad
- Mostly due to $K^+ \rightarrow \pi^+ \pi^0$ decays
- For $E_{\pi} < 35$ GeV 80% of the photons are in the Lkr acceptance
- Inefficiency $< 10^{-5}$ for $E_\gamma > 10$ GeV
Too many data to be read at L0. Waiting for L1 response.
THE LKr TRIGGER PROCESSOR

- Instantaneous rate: 30 MHz
- Latency: < 100 µs

Pixel-based trigger processor with 4x4 calorimeter cell tiles (Super-Cells)

Identifies em clusters and prepares a time-ordered list (time, position and energy) for the L0 Trigger Processor.

- Front-End boards (28): peaks in time indipendently searched in each vertical slice: digital constant fraction discriminator + linear interpolator for fine timing.
- Merger boards (7): peaks close in space and time merged and assigned to the same electromagnetic cluster.

LEVEL ZERO TRIGGER PROCESSOR

- UDPs sent in frames with a period of 6.4 us;
- **Unsorted primitives** form 7 different sources received by L0TP:
  - first alignment at UDP frames;
  - fine alignment of primitives using time addressed rams;
- In time primitives compared with pre-selected masks using an **associative memory**;
- Triggers sent in phase with the 40 MHz clock;
- Triggers are sent after a programmable latency (up to 1 ms).

**L0TP Design values:**

LEVEL ZERO TRIGGER PROCESSOR IN 2016

$L_0$ Trigger Rate$_{2016} \sim 435\text{kHz}$

- Trigger coincidences online: ±5 ns
- ~40% of the nominal @ ~40% of beam intensity.
RICH-GPU TRIGGER PROCESSOR

The measure of a man is what he does with power
Plato
**RICH-GPU TRIGGER PROCESSOR**

GPUs provide a huge computing power on a single device, thus allowing to take complex decisions with a significantly high speed capable to match valid event rates.

**GOAL:** RICH-Ring reconstruction directly on GPU. Very clean tag/veto system at level-0

Problems to be investigated:
- Are GPUs fast enough to take trigger decision at tens of MHz events rate?
- Is the latency along the whole data path (Detectors -> GPU -> Trigger) stable enough for usage in synchronous trigger systems?
**LATENCY: MAIN PROBLEM OF GPU COMPUTING**

- Data coming from the detectors are received from the Network Interface Card
- Data must be moved/copied between Host and Device
- Latency fluctuations due to OS

**NaNet** is an FPGA-based PCIe NIC with real-time data transport architecture
- Allows direct data exchange over the PCIe bus with no CPU involvement
- Zero copy I/O
- Perform preprocessing on data stream on the NIC
GPU HARDWARE ENVIRONMENT

NaNet design implemented on an ALTERA Stratix V FPGA dev board (Terasic DE5-NET)

- PCIe x8 Gen2
- 4 SFP+ ports (four 10GbE 10GBASE-KR)
- GPUDirect RDMA capability
- UDP protocol offload
- Real-time stream processing on the FPGA:
  - Decompression and Merging of events
  - Arranging data for optimal GPU memory access (data alignment)

Results can be directly injected from GPU memory into the network
GPU ALGORITHM

- XY plane divided into a grid
- A histogram is created with distances from these points and hits of the physics event
- Rings are identified looking at distance bins whose contents exceed a threshold value

- **Pros**: naturally mapped on the GPU threads grid
- **Cons**: local memory limited, performances depending on number of events/hits

- Trackless
- Multi-rings
- Fast
- Low latency
- Accurate
GPU RESULTS

Two GPUs tested in lab:
- Tesla K20
- Pascal P100

At 2000 events:
- K20 ~ 0.5 us/evt
- P100 ~ 100 ns/evt

Pascal P100 makes the ring reconstruction latency on GPU compatible with the experiment requirements.

Tests at the experiment are ongoing.
High Level Triggers

They say they have you on tape, pulling the trigger!
Prison Break – Seasion 1 – Episode 16
HIGH LEVEL TRIGGERS

L1 from 1 MHz to 100 kHz

L2 from 100 kHz to 10 kHz

colorimeters GTK

HLTs are running online on 30 PCs. L1 algorithms selects data using the information coming from:

KTAG → incoming particles has to match with a Kaon;

LAVs → events with photons at large angle are veto;

STRAWs → cut on topology and momentum of the tracks;

Dario Soldi - NA62 Trigger and Data Acquisition
Kaon TAGger

Differential Cerenkov detector
- Reduces of a factor 2.5 the L0 rate;
- Reduces of a factor 10 the beam halo tracks;
Large Angle Vetos And Straws

LAVs

- **Hit-multiplicity cut** in the twelve LAV stations
- reduction of $K^+ \rightarrow \pi^+ \pi^0$ background by identifying photons at large angles.
- **Trigger efficiency** on a single-track event > 95%
- **Data reduction** ~20%

STRAWs

- **Hough transform** to define a track
  - Position of vertex
  - closest distance of approach to the beam axis
- **Crude momentum evaluation**
- **Trigger efficiency** on signal > 99%
- **Data reduction** ~40%
Conclusions

*Si finis bonus est, totum bonum erit.*

*Gestae Romanorum*
CONCLUSIONS

- The NA62 TDAQ system is quite peculiar with respect to other collider trigger systems:

- The timing resolution appears fundamental already at the level-0 trigger in order to reject the high background.

- All the systems involved in the trigger have a level-0 time-resolution < 2.5 ns.

- NA62 is able to digest ~14 MHz of decay-products reducing them at 1 MHz after level-0 and 100 KHz after level-1 triggers.

- Monitoring systems allow reproducing the trigger conditions offline, giving the possibility of data-driven trigger simulations.

- GPU level-0 trigger system is under development.

- NA62 is triggering its $\pi vv$ events, analysis is going on to make them emerging from the data.
THANK YOU for your ATTENTION!

additional material
RICH-NA48 CHOD L0 TRIGGER GENERATORS

- produce **time-clusters of hits** belonging to the same event.
- provide **precise time reference** (100 ps time resolution) and hit count.
- No geometrical or detector-specific information is used.

- A Data Converter reads TDC data and converts them in the trigger processor format.
- A Data Merger in the SL mergers the clusters coming from 4 PP-FPGAs at a rate of 1 word per clock cycle.
- The data merger is purely combinatorial
- This module can handle a 1024–16=1008 words per 6.4us frame
  - **Anomalous instantaneous high rate are absorbed in dedicated buffers**
- An Average Calculator module computes the weighted mean of the clusters’ times with a 8-bit FPGA-embedded divider.

It calculates the new cluster as:

\[
\text{Seed}_{\text{new}} = \text{Seed}_{\text{old}} + \text{SUM}_{\text{old}} / N_{\text{old}}
\]

\[
N_{\text{new}} = N_{\text{old}}
\]

\[
\text{SUM}_{\text{new}} = 0
\]

A Primitive Builder formats the incoming data in the standard NA62 format, computes the ID for each primitive and sends it to the standard assembler module and then to the L0TP.

+ Pedestals before and in burst + LKr calibrations at the end of beam extraction.
HIGH INTENSITY BEAM

Rate after target: ~800 MHz;
Rate of Kaons: ~50 MHz (6%) = 5 x 10^7 Kaon/s;
burst/year: #days (100) x 24 h x 60 min x 3 burst/min: 4 x 10^5;
Kaon decays/year: 3 seconds x 4 x 10^5 burst/year x 5 x 10^7 Kaon/s = 5 x 10^{13};
Decays in fiducial region: 10%;
Decay in the detector acceptance: 10%;
Total Kaon decay collected/year: = 5 x 10^{11};

In one year of data taking we expect:
40 K^+ -> π^+vv if standard model BR;
THE IMPORTANCE OF BEING $K^+ \rightarrow \pi^+ \nu \bar{\nu}$

- Models with a CKM-like structure of flavour interactions (e.g. MFV);
- Models with new flavour and CP-violating interactions in which either left or right handed currents fully dominate (e.g. $Z$ or $Z'$ FCNC scenarios);
- More specifics NP models like Randall-Sundrum;

[Complementary to LHC]

EFFECTIVE SPILL LENGTH

To calculate the rates, the effective length of the spill is required:

Rates calculated using the Effective Spill Length:

$$T_{eff} = \frac{\left[ \int_0^T F(t) dt \right]^2}{\int_0^T F(t)^2 dt}$$

$F(t)$: beam current as a function of time, approximated with the number of primitives.

**Best value: 3.8 s.**
CLOCK AND TIMING DISTRIBUTION

**TTC**
The TTC (Timing and Trigger Control) system encodes on the same single-mode optical fibre:
- Clock.
- Synchronous triggers pulses.
- Start of Burst (SOB).
- End of Burst (EOB).
- CHOOSE/ERROR triggers (asynch).

**Local Trigger Unit (LTU)**
- Receive trigger from the L0 Trigger Processor.
- Encode triggers and send to detector TTCex.
- Receive CHOOSE/ERROR signals from detector and propagate it to L0TP.
