

Exotic and Conventional Quarkonium Physics Prospects at Belle II

Thursday 30 August 2018 17:30 (25 minutes)

The Belle II experiment, now operating at the KEK laboratory in Japan, is a substantial upgrade of both the Belle detector and the KEKB e^+e^- accelerator. It aims to collect 50 times more data than existing B-Factory samples. Belle II is uniquely capable to study the so-called “XYZ” particles: heavy exotic hadrons consisting of more than three quarks. First discovered by Belle, these now number in the dozens, and represent the emergence of a new category within quantum chromodynamics. This talk will present the capabilities of Belle II to explore both exotic and conventional quarkonium physics.

Presenter: SCAVINO, Bianca (Uni Mainz)

Session Classification: Heavy Quarks

Track Classification: Heavy Quarks
