

# Higgs physics at the CMS experiment

Claudio Caputo <sup>1</sup>, on behalf of CMS collaborations

<sup>1</sup> Centre for Cosmology, Particle Physics and Phenomenology (CP3),

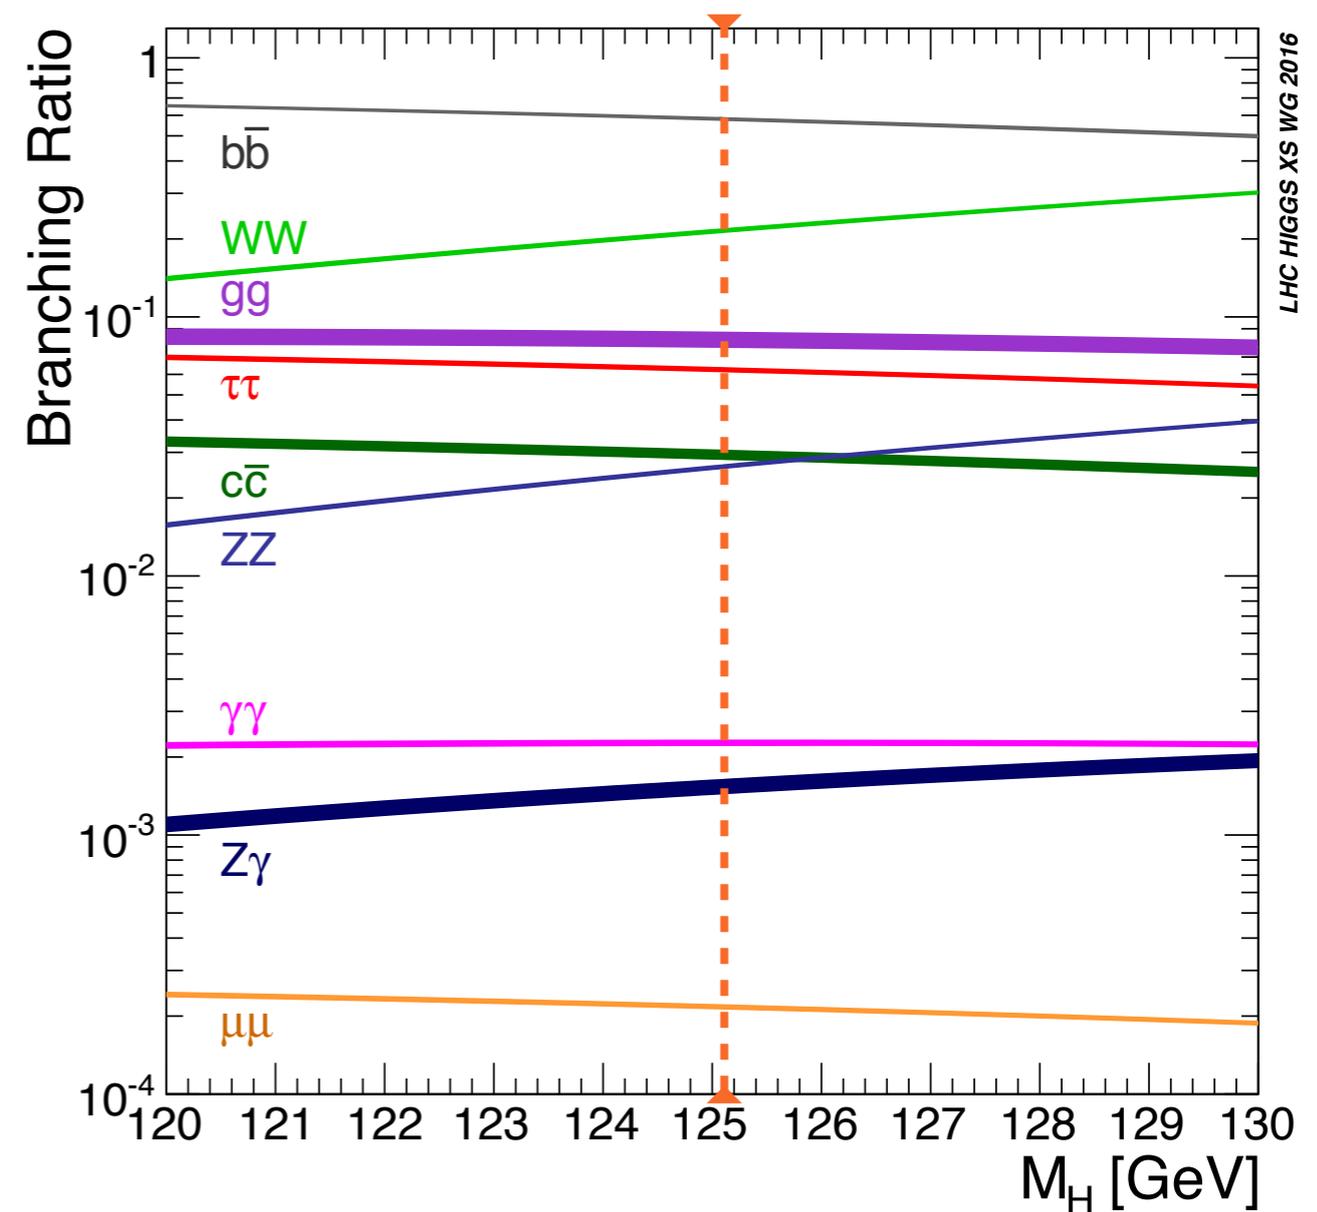

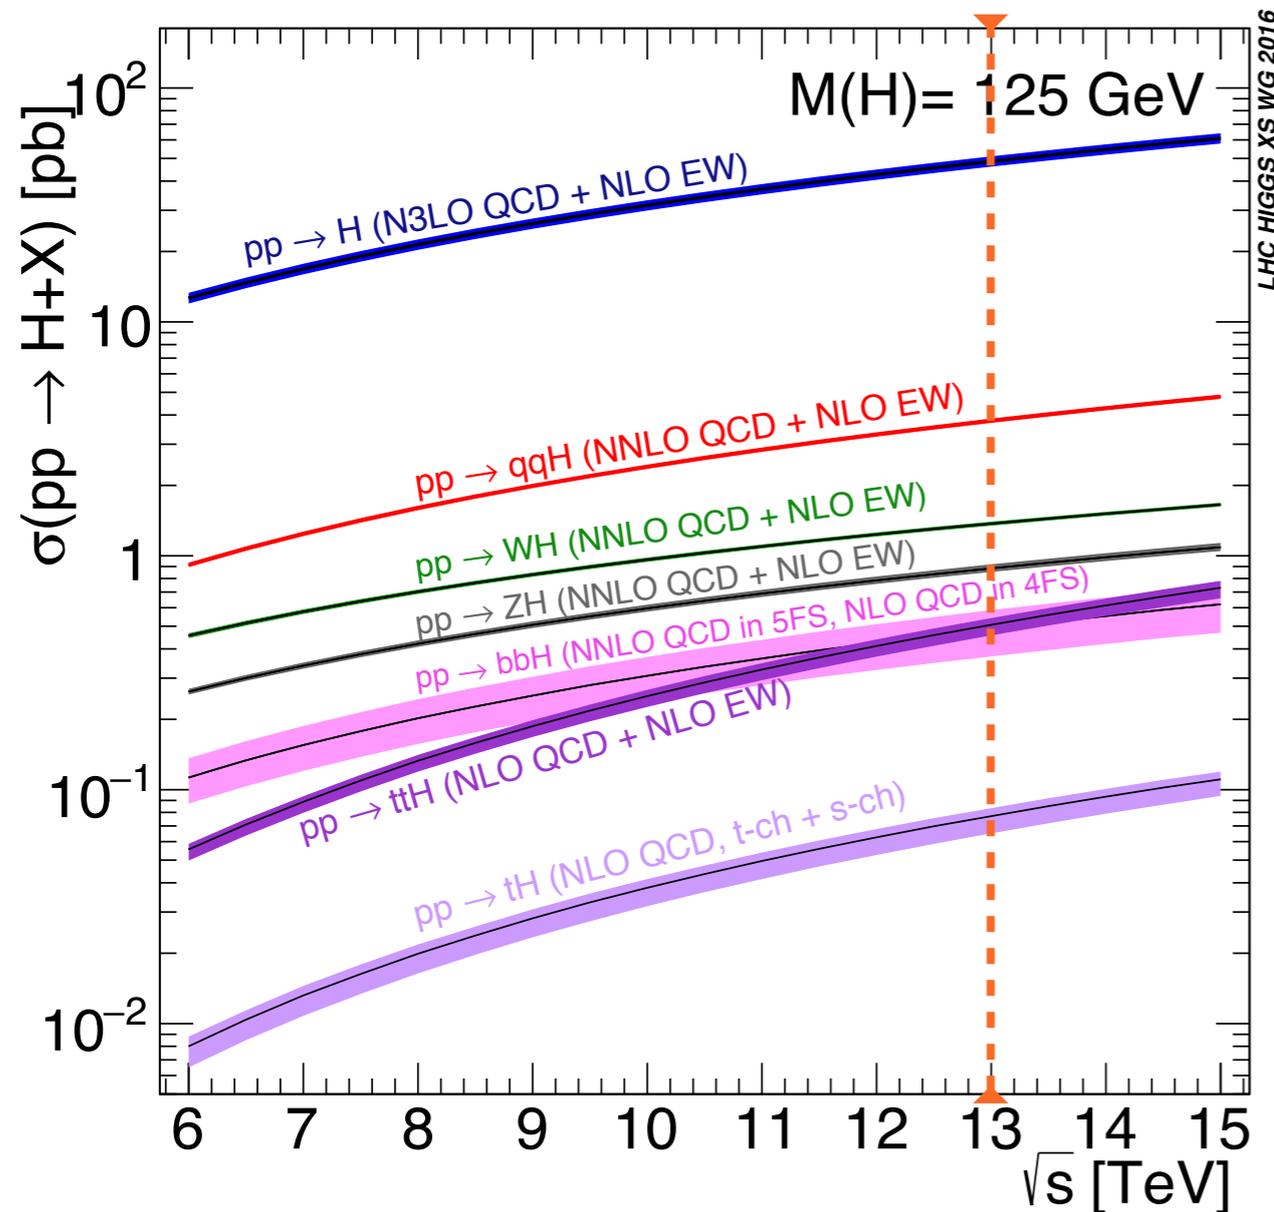

Université Catholique de Louvain

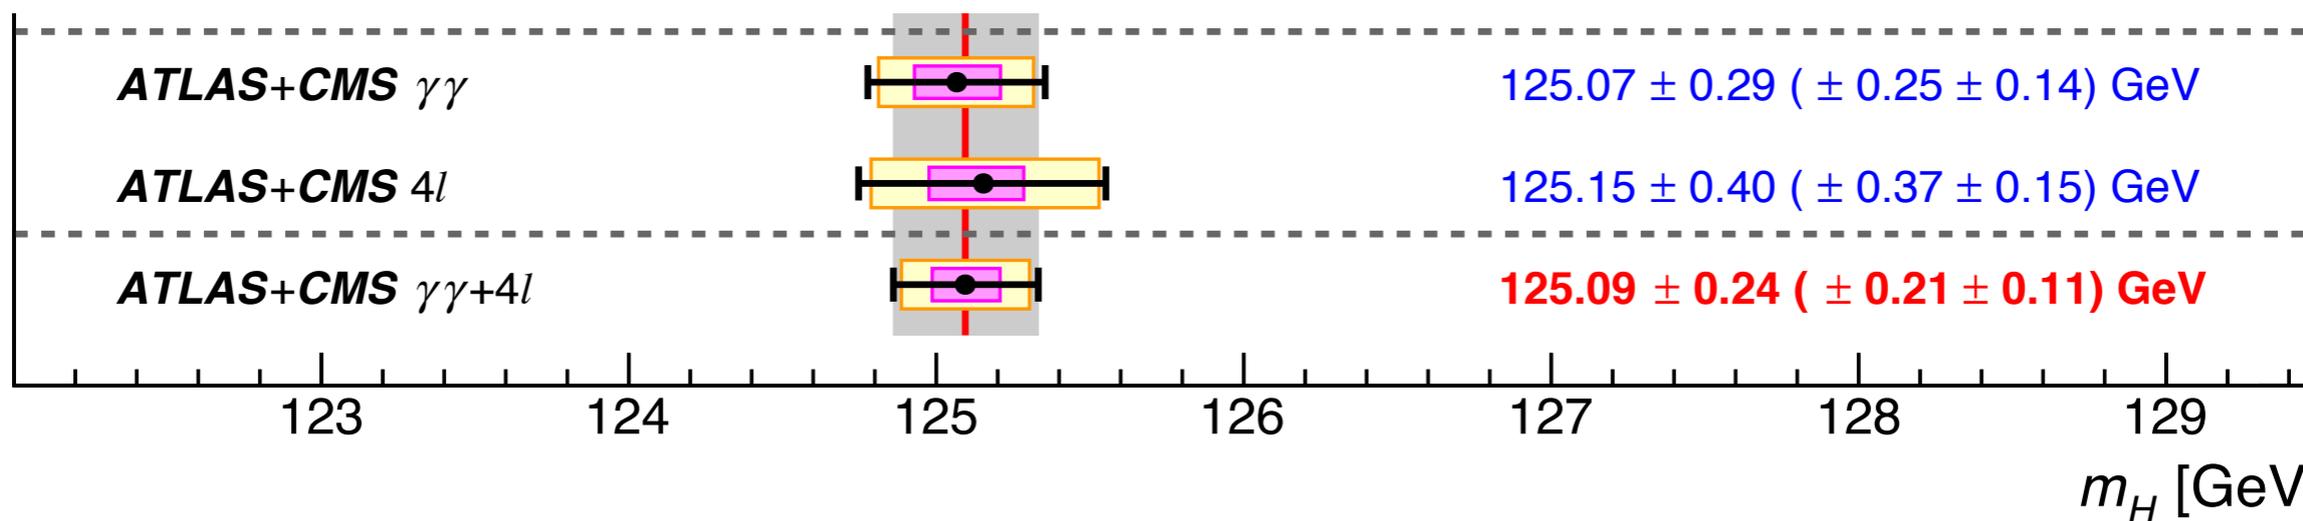

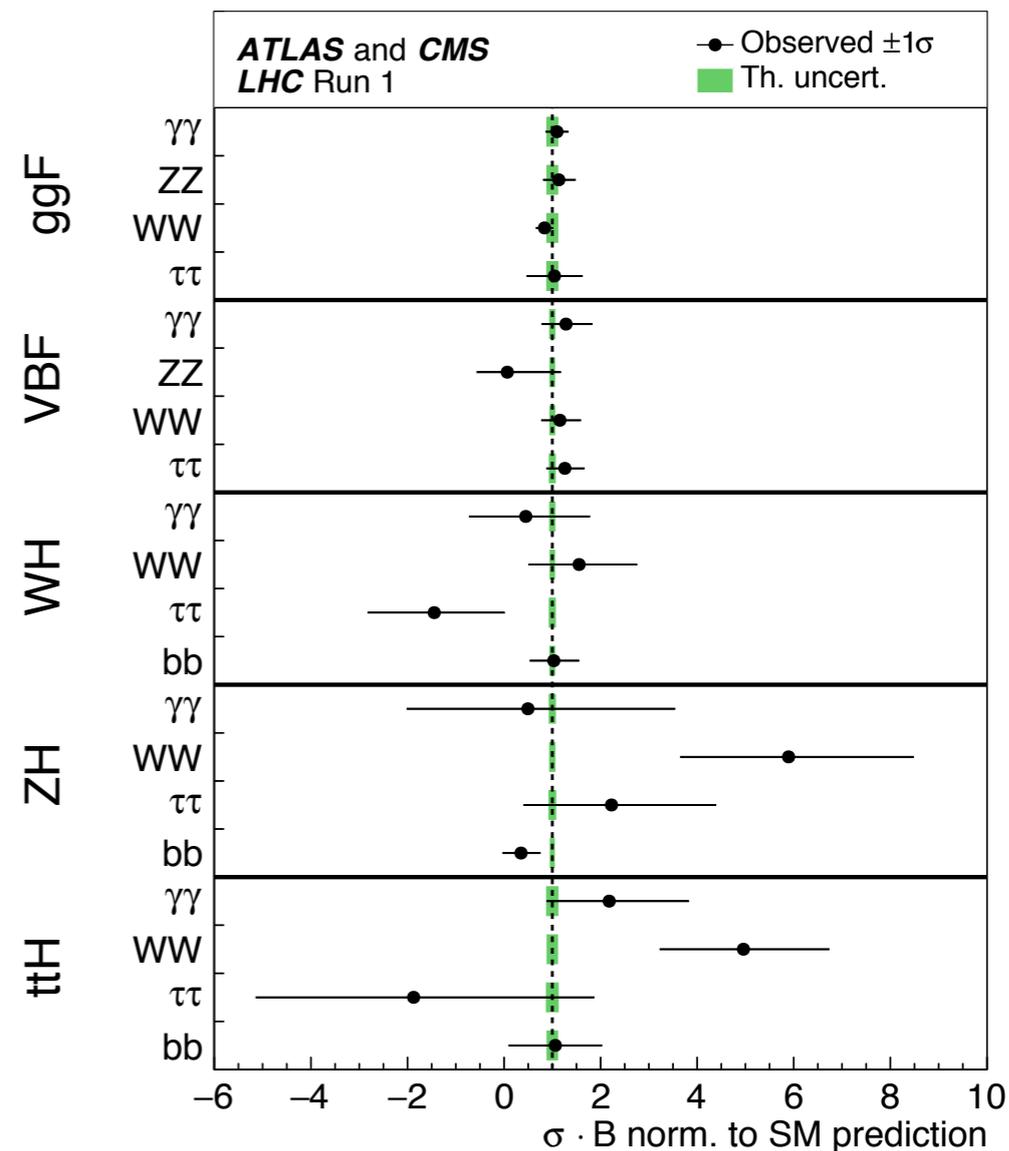

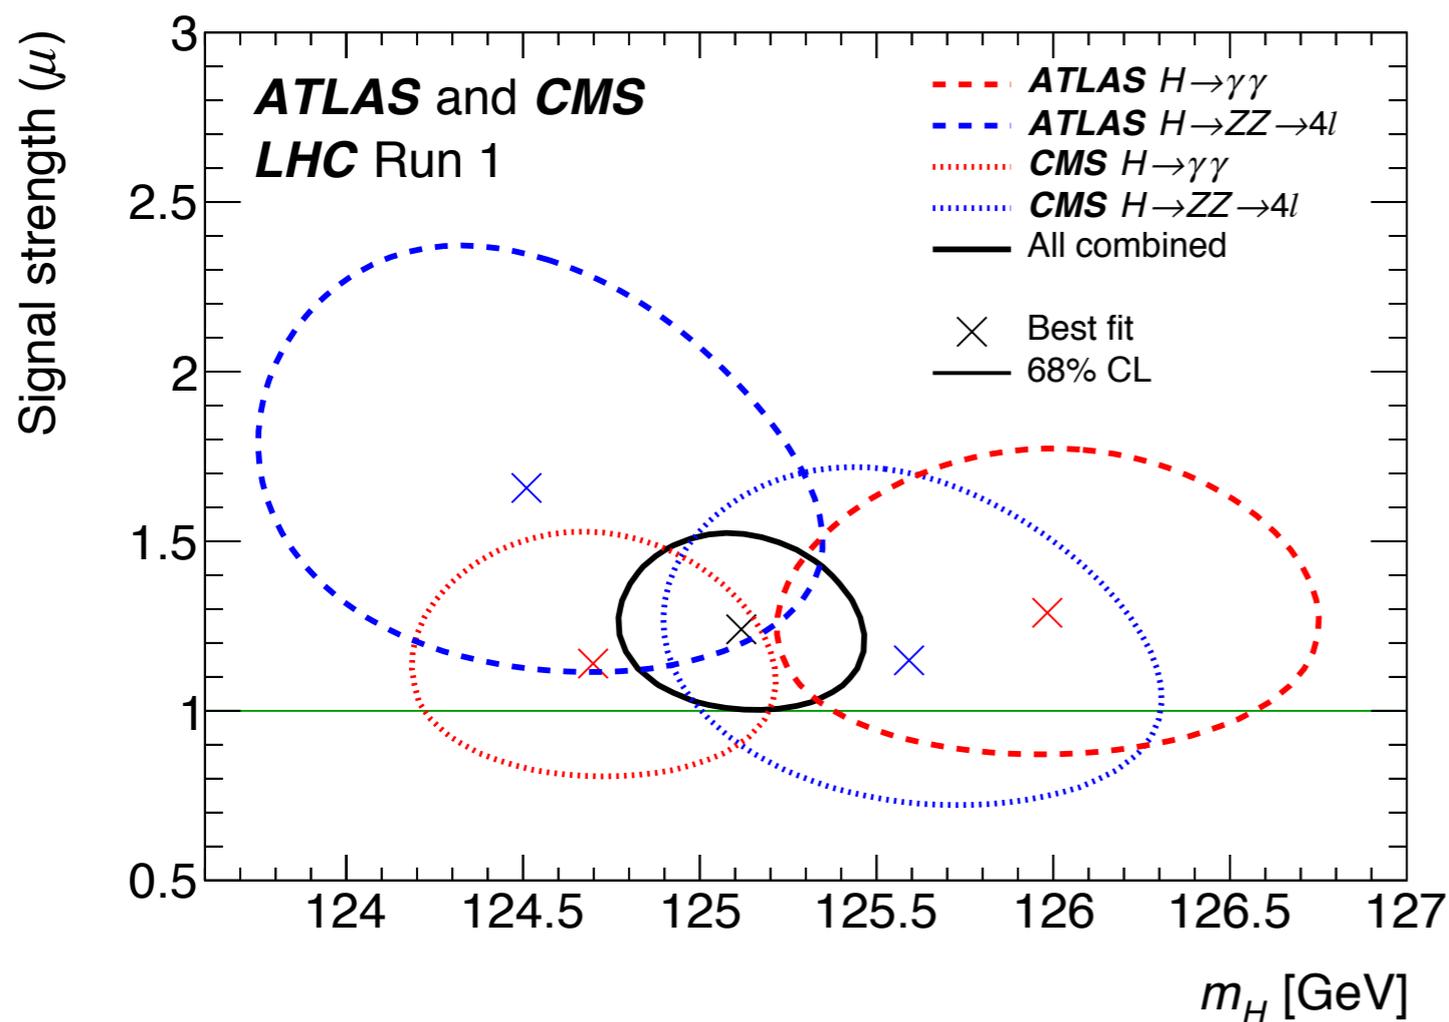

7th International Conference on New Frontiers in Physics, 4-12 July 2018, Kolymbari, Crete, Greece

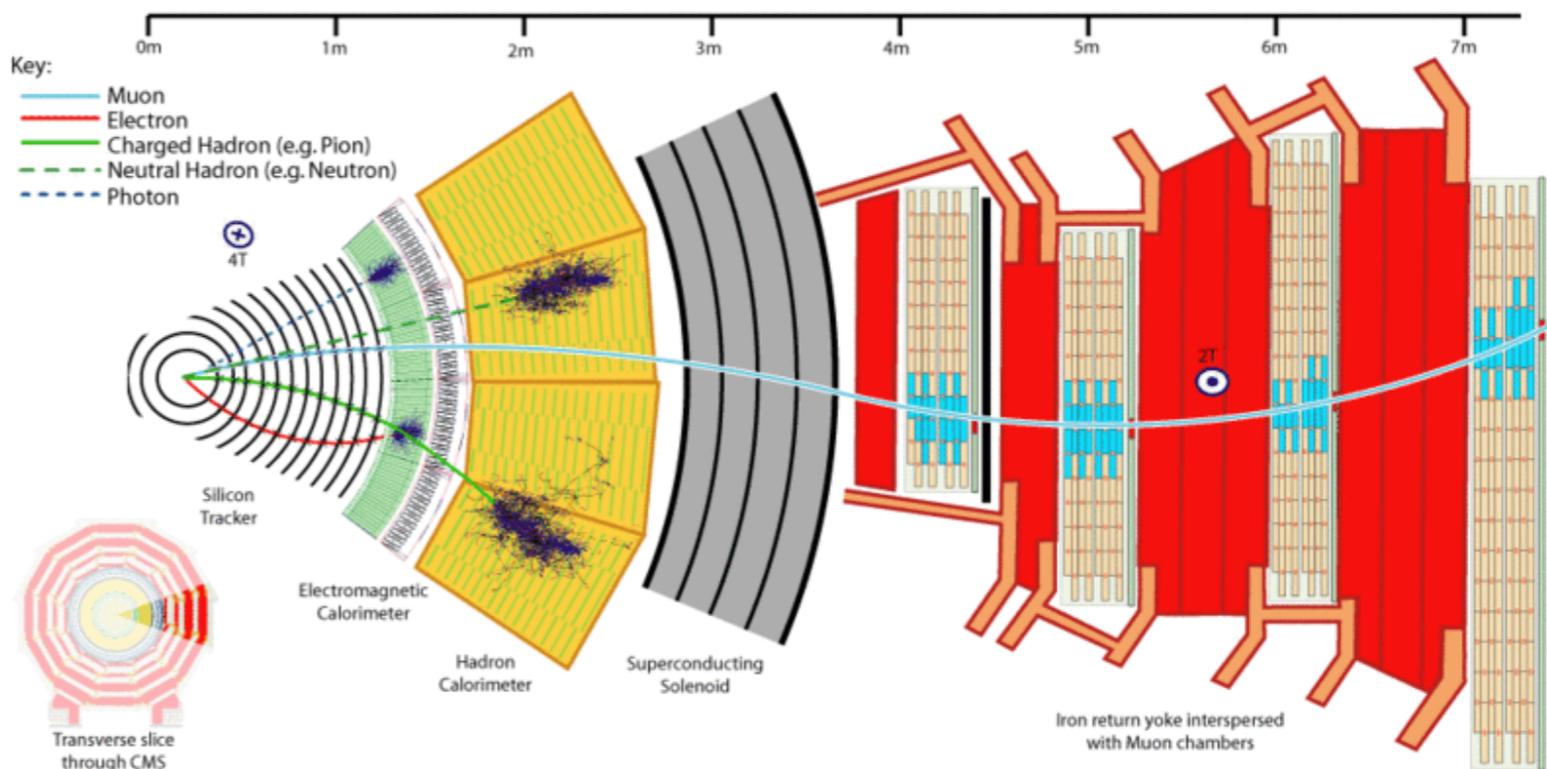

- ▶ After the **Higgs discovery** in 2012, the **emphasis shifted towards measuring the properties of this new particle.**
  - The mass, the width, the spin and parity
  - Couplings, several models for physics beyond the SM predict (small) deviations in the couplings for the Higgs boson.
- ▶ This talk will **review the latest results using the Run 2 CMS dataset.**
  - Increased collision energy (13 TeV) means an increased cross section for signal and background, with the most significant gain for processes involving heavy particles like multiple top quarks.
  - Most of the **Run 1 results have been reproduced using 2016 dataset** (35.9 fb<sup>-1</sup>) and **combined** increasing the precision on couplings measurement.
  - **New results with the 2016 dataset and first results with the 2017 data results** (41.5 fb<sup>-1</sup>) will be discussed

- ▶ Given the mass of 125 GeV, we know the branching fractions from theory.
- ▶ Several production modes of the Higgs boson possible at the LHC, sometimes with associated particles.

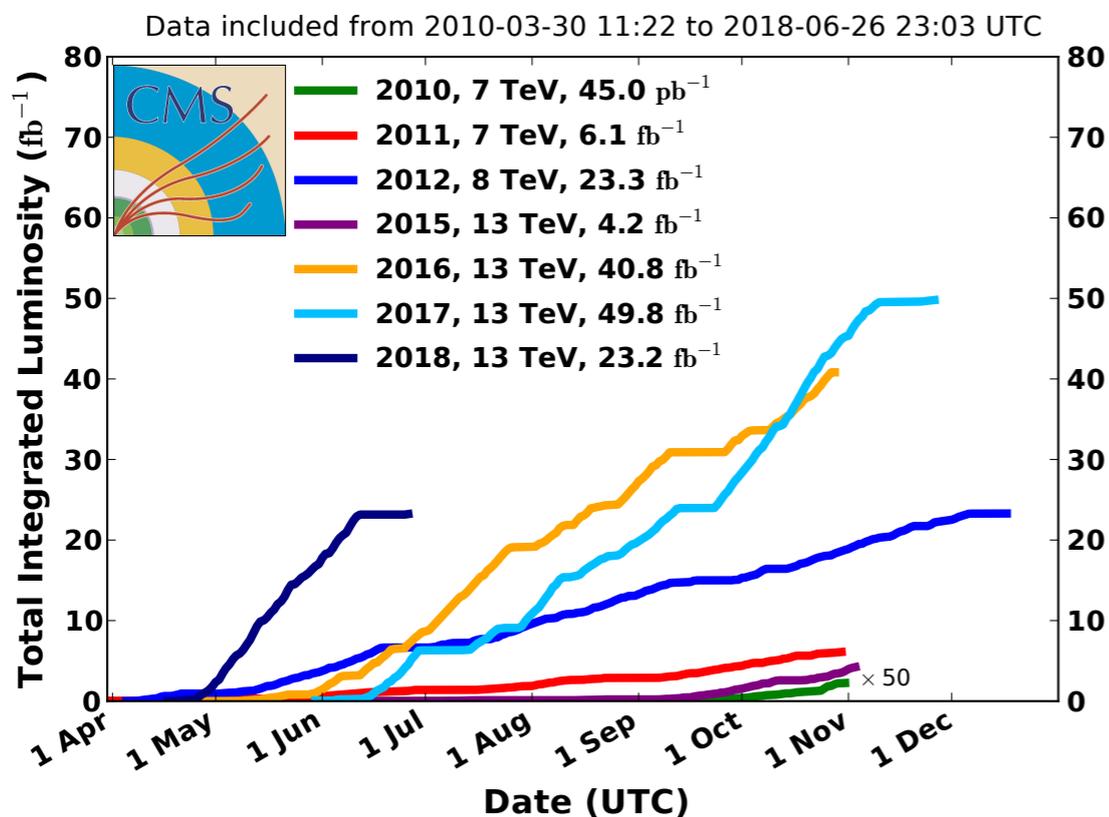

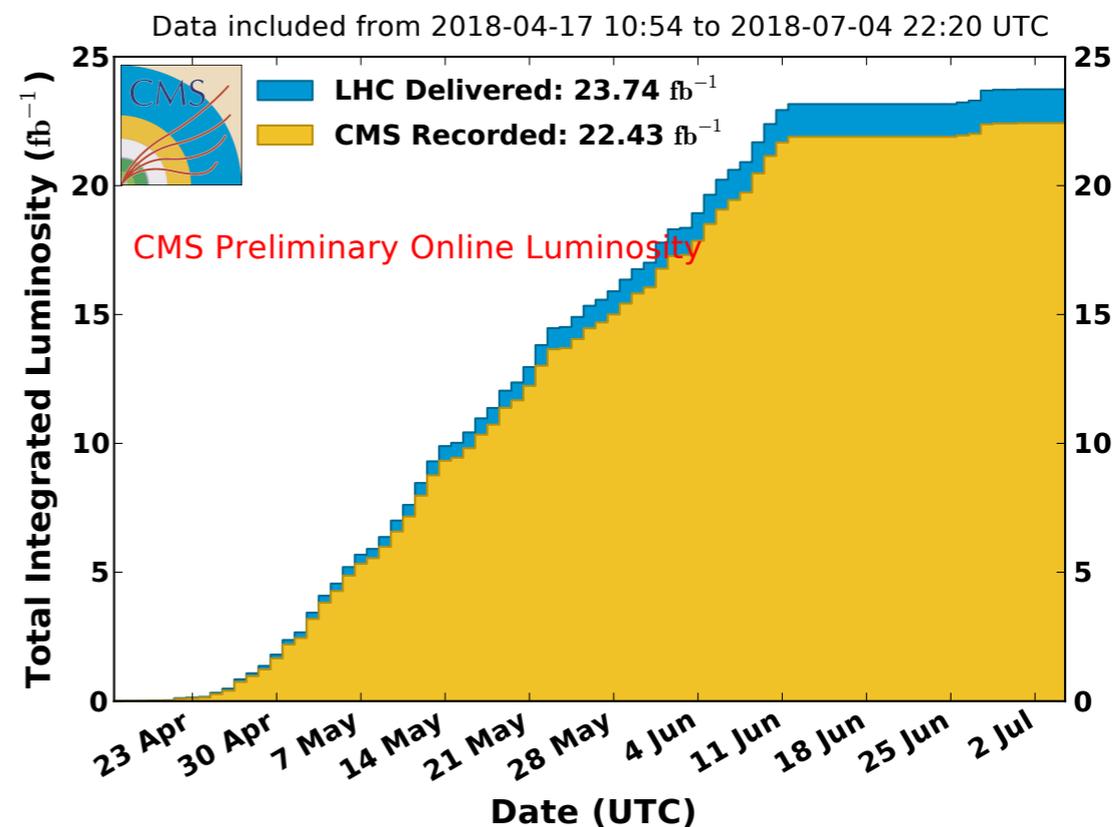

- ▶ Multipurpose detector at Large Hadron Collider
- ▶ Excellent performances of both CMS and LHC so far in Run-2
- ▶ CMS has recorded  $\sim 110 \text{ fb}^{-1}$  of 13 TeV data, of which  $\sim 90\%$  certified as good for physics analysis

CMS Integrated Luminosity, pp

CMS Integrated Luminosity, pp, 2018,  $\sqrt{s} = 13 \text{ TeV}$

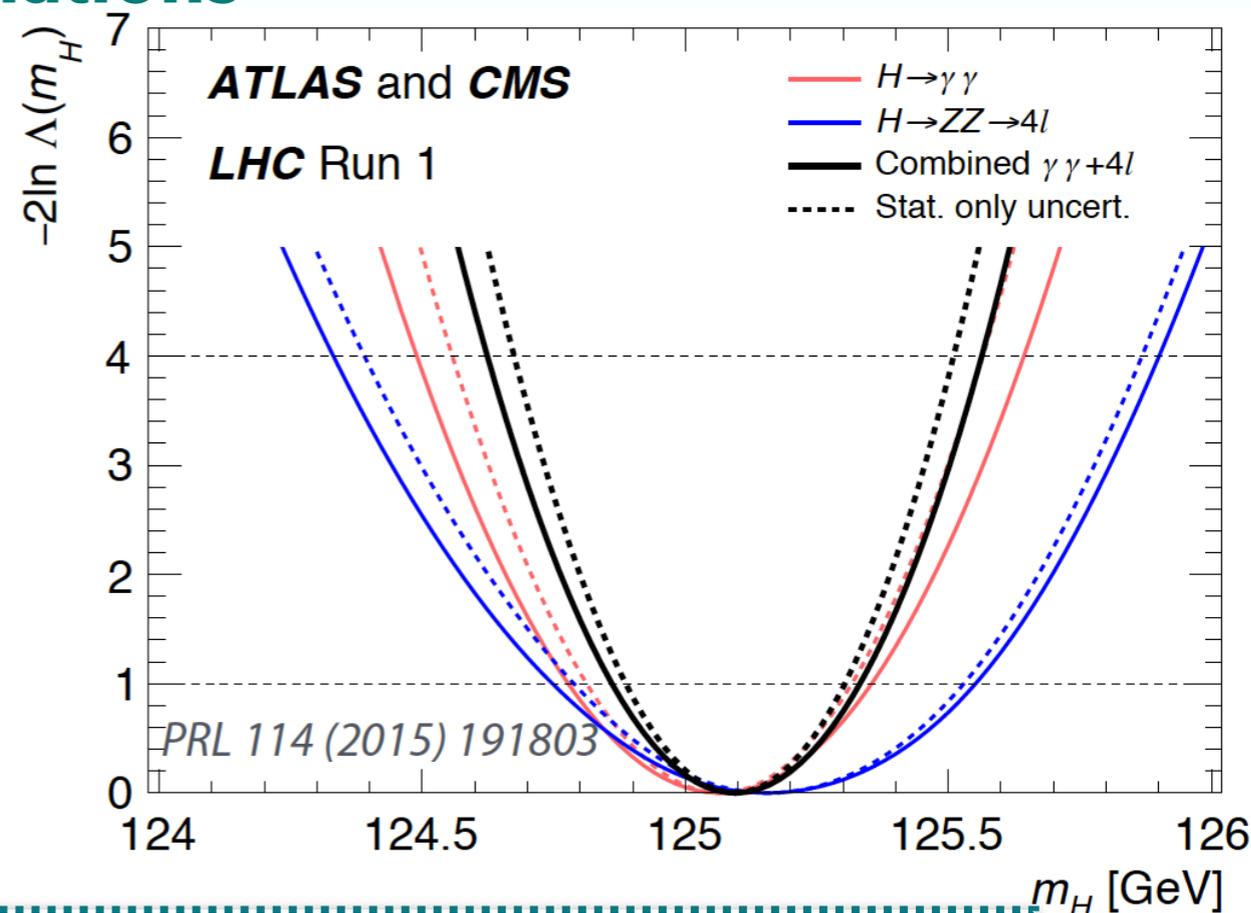

# Run 2 – Couplings

- ▶ Higgs boson discovery via the benchmark  $H \rightarrow ZZ \rightarrow 4l$  and  $H \rightarrow \gamma\gamma$  channels the legacy of Run 1
- ▶ Focus in **Run 2** is making **precise measurements** of its properties to assess compatibility with the SM
- ▶ High precision measurement of the couplings essential as **BSM physics** can manifest as **percent-level deviations**

▶ **All combined** measurements presented assume **fixed  $m_H$**

- Use Run 1 CMS+ATLAS combination of high resolution  $H \rightarrow \gamma\gamma$  and  $H \rightarrow ZZ \rightarrow 4l$  channels

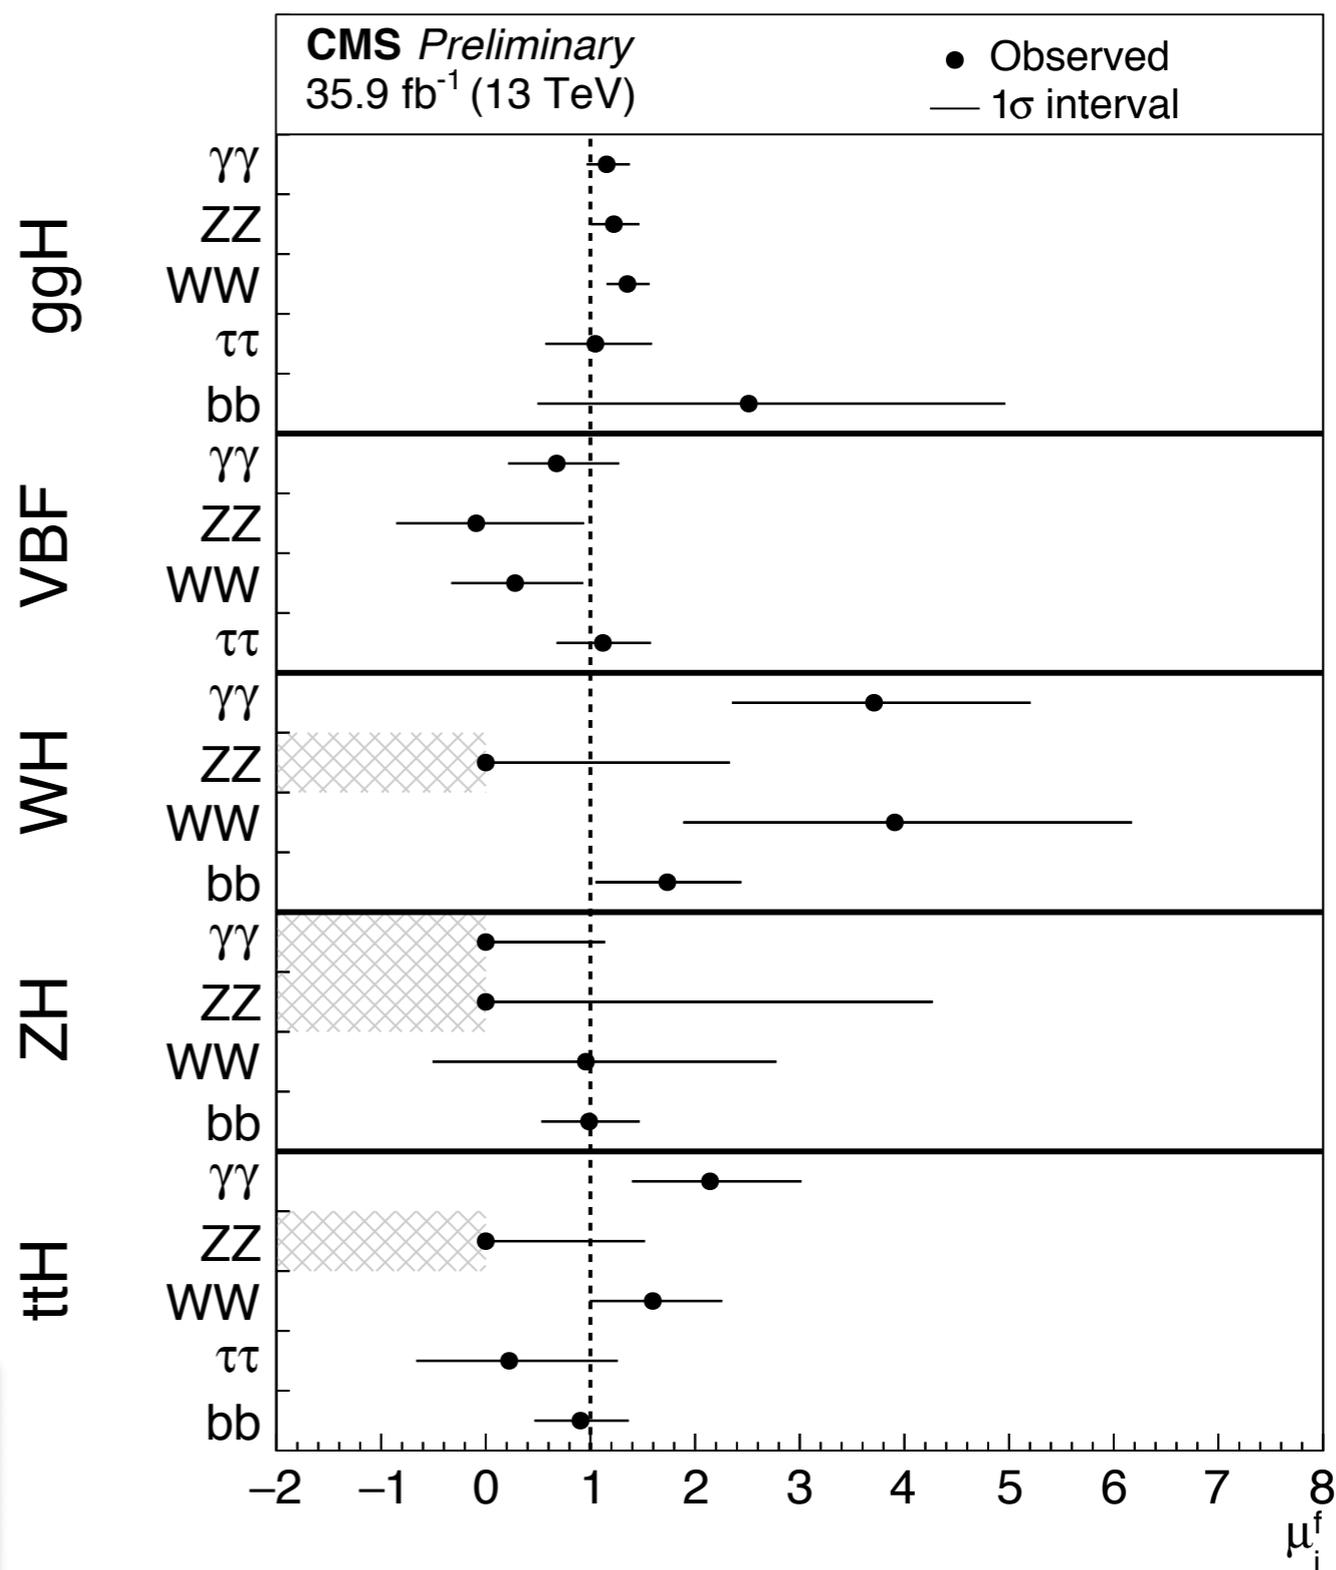

$$m_H = 125.09 \pm 0.21 \text{ (stat.)} \pm 0.11 \text{ (syst.) GeV}$$

- ▶ **Analyses used** for combination cover all main production and decay modes on **2016 13 TeV dataset** (35.9 fb<sup>-1</sup>)
  - VH(→ττ) missing
- ▶ Total of **250** individual categories (counting signal and control regions) and ~ **5400** nuisance parameters in the combined fit
- ▶ Signal strength measurements
  - Parameters scale cross sections and BRs relative to SM

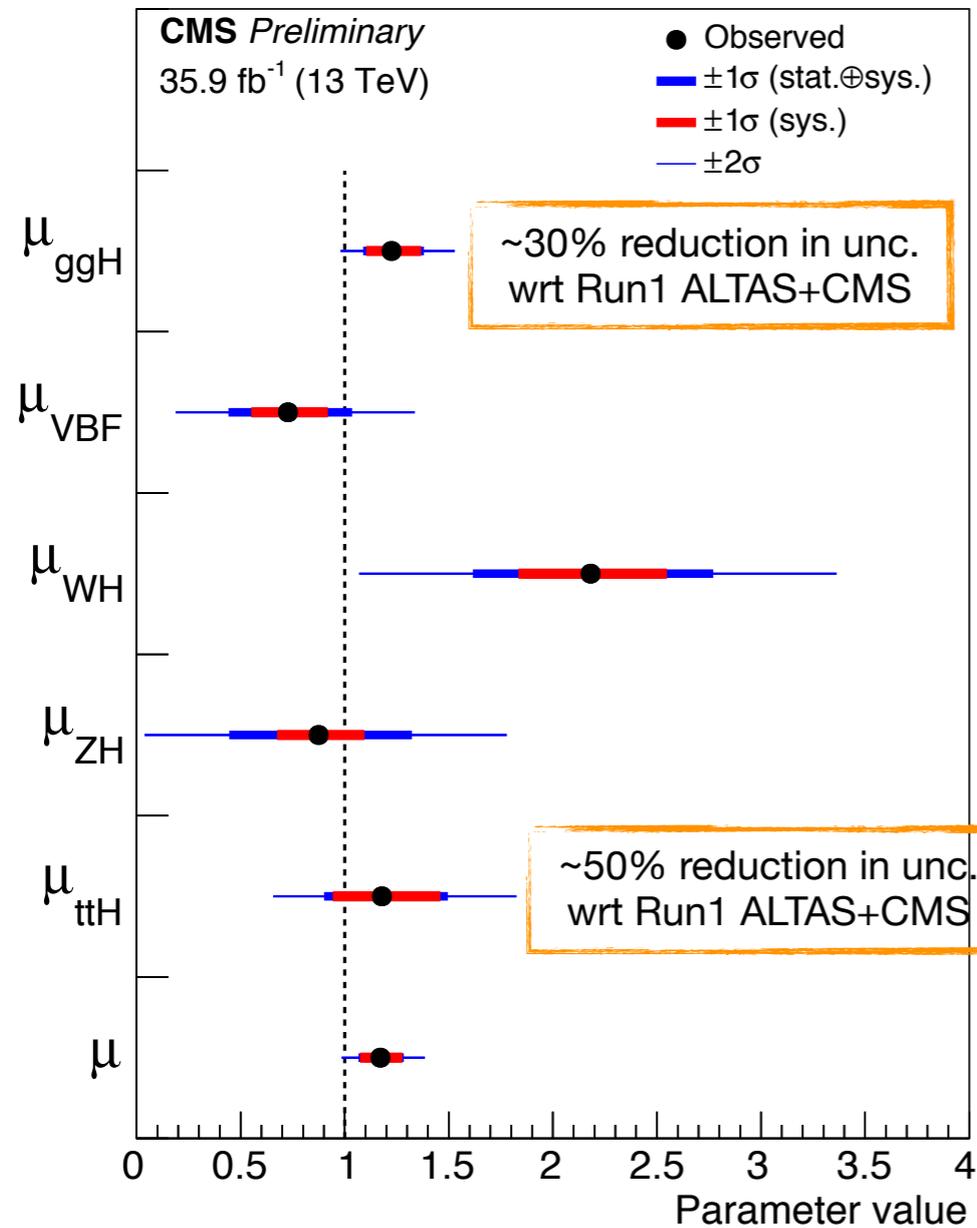

$$\mu_i = \frac{\sigma_i}{\sigma_i^{SM}} \quad \mu^f = \frac{BR^f}{BR_{SM}^f}$$

$$\mu_i^f \equiv \frac{\sigma_i \cdot BR^f}{(\sigma_i \cdot BR^f)_{SM}} = \mu_i \times \mu^f$$

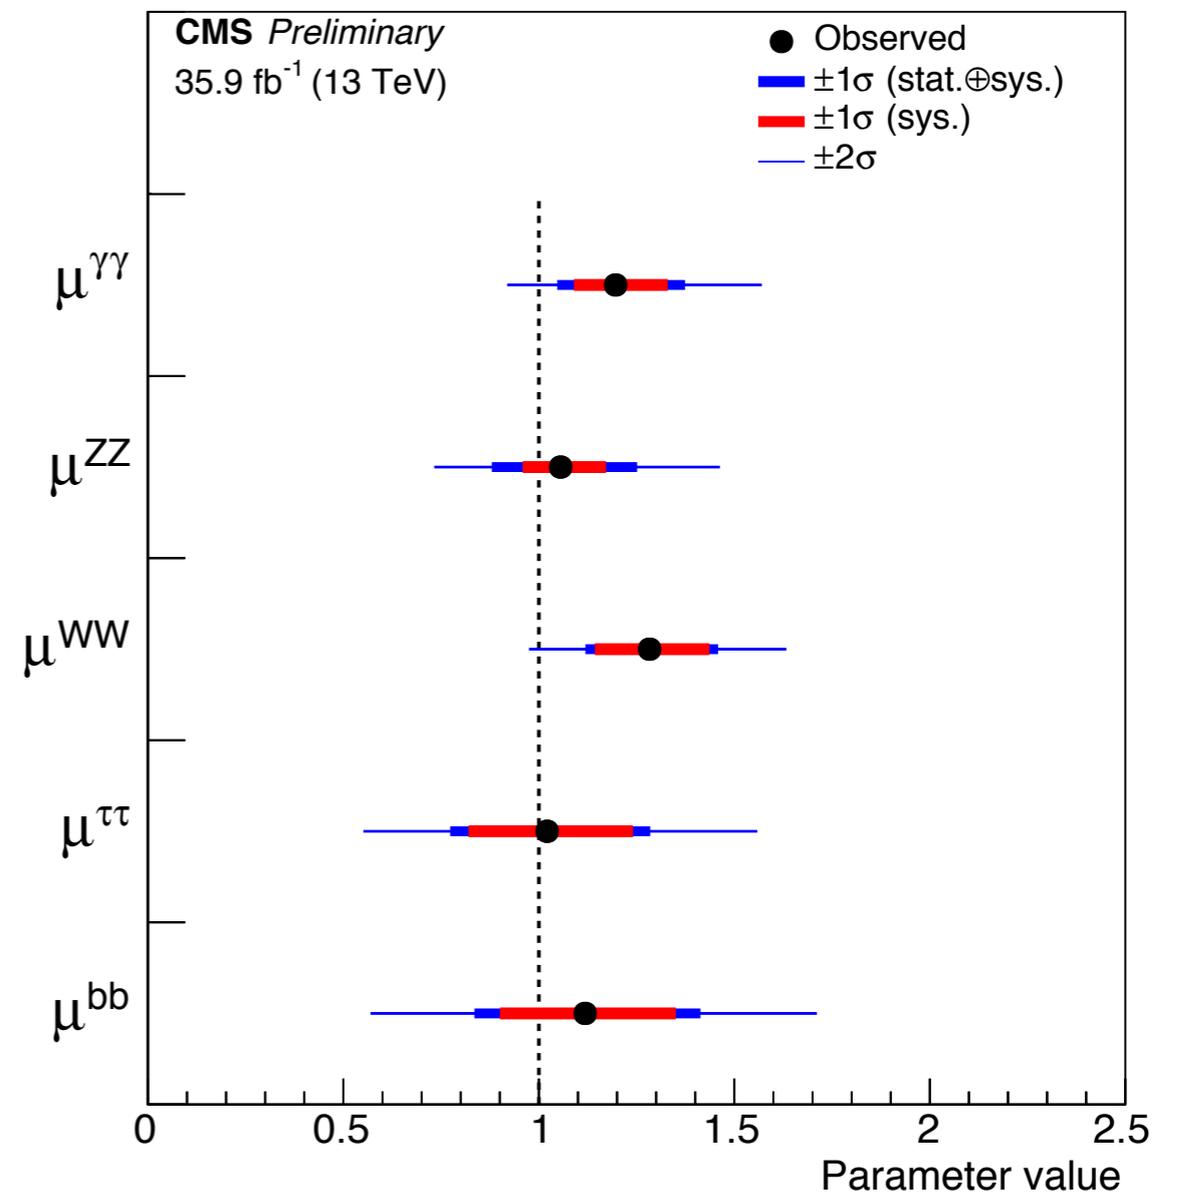

► Signal strength measurements

## Production Mode

## Decay Mode

$$\mu = 1.17^{+0.10}_{-0.10} = 1.17^{+0.06}_{-0.06} \text{ (stat.) } ^{+0.06}_{-0.05} \text{ (sig. th.) } ^{+0.06}_{-0.06} \text{ (other sys.)}$$

- ▶ Use the LO coupling modifier or "kappa" framework to probe for deviations from the SM
  - Parameters scale cross sections and partial widths relative to SM
- ▶ Option to consider decay to BSM particles via  $\text{BR}_{\text{BSM}}$  term which also scale total width

$$\kappa_j^2 = \sigma_j / \sigma_j^{\text{SM}} \quad \kappa_j^2 = \Gamma_j / \Gamma_j^{\text{SM}}$$

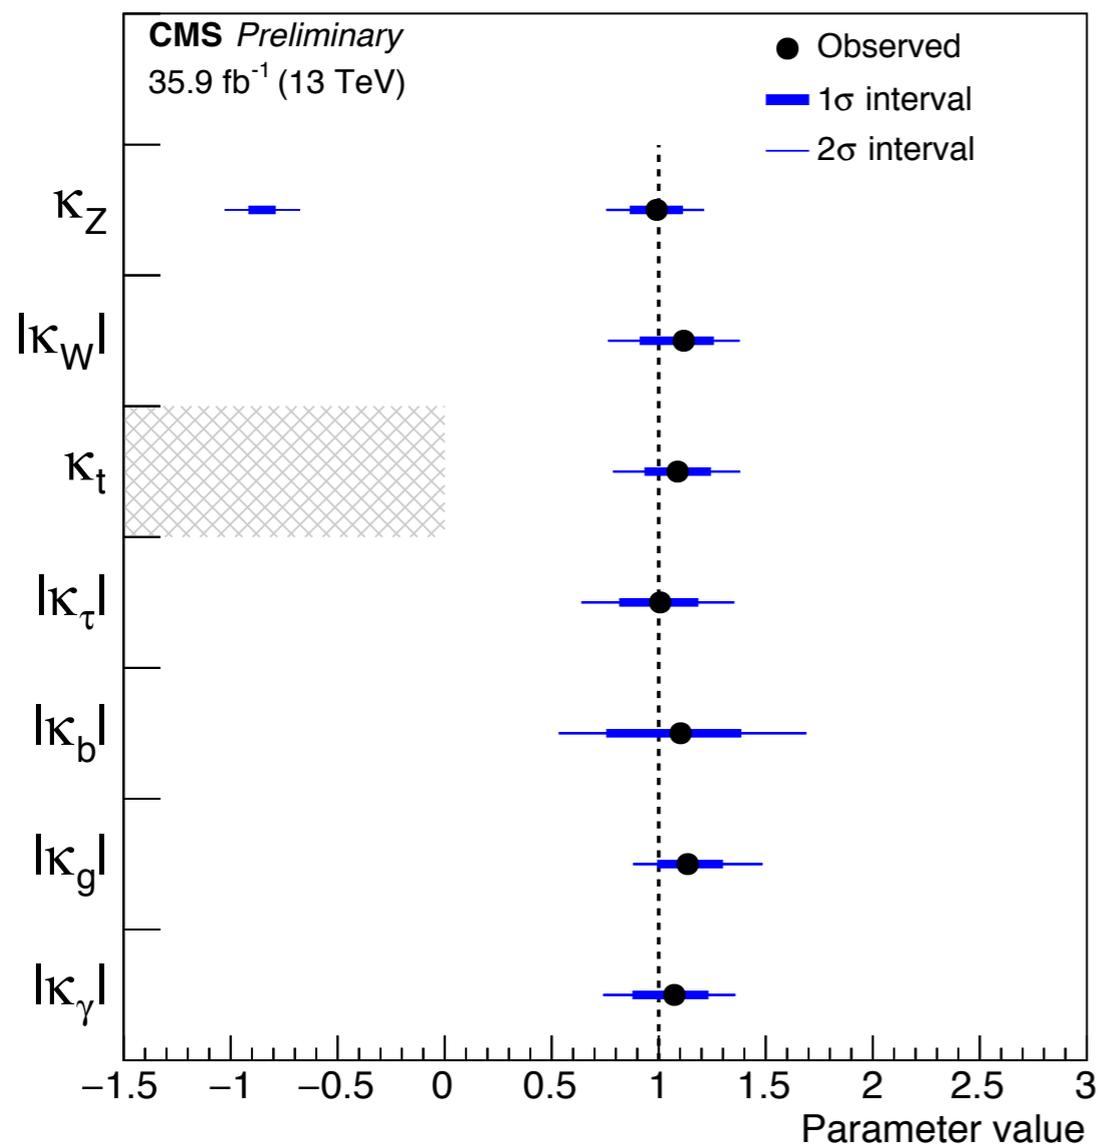

$$\sigma_i \cdot \text{BR}^f = \frac{\sigma_i \cdot \Gamma_f}{\Gamma_H}$$

$$\Gamma_H = \frac{\kappa_H^2 \cdot \Gamma_H^{\text{SM}}}{1 - \text{BR}_{\text{BSM}}}$$

$$\kappa_H^2 = \sum_j \text{BR}_{\text{SM}}^j \kappa_j^2$$

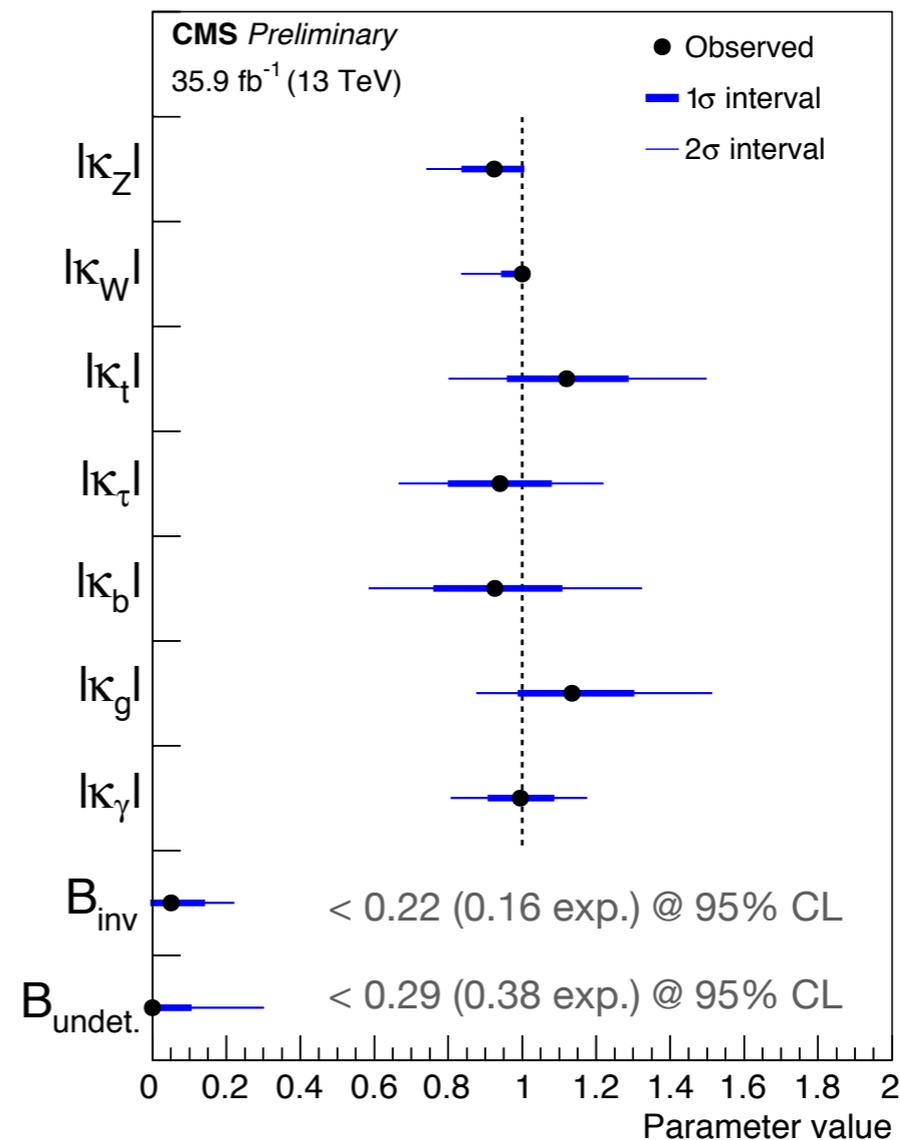

$$\text{BR}_{\text{BSM}} = \text{BR}_{\text{inv.}} + \text{BR}_{\text{undet.}}$$

$BR_{inv} = 0, BR_{undet} = 0$

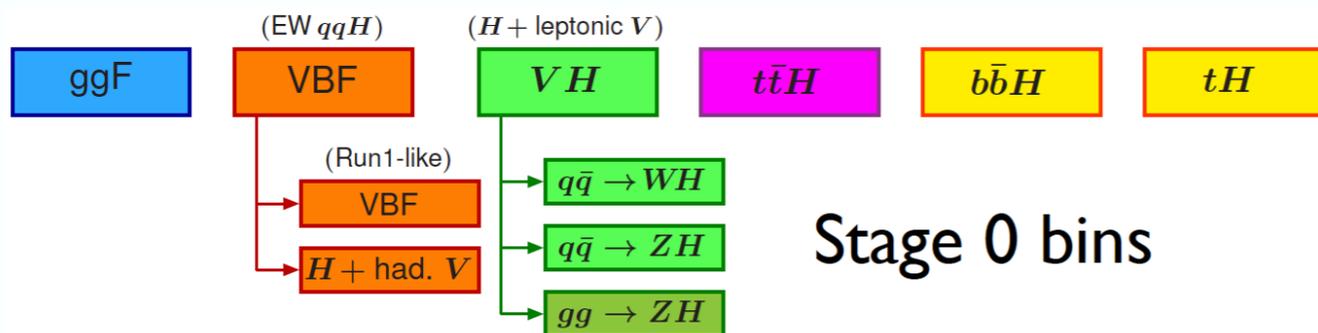

- ▶ Sensitive to relative  $\kappa_Z$  and  $\kappa_t$  sign via ggZH interference

$BR_{inv} > 0, BR_{undet} > 0$

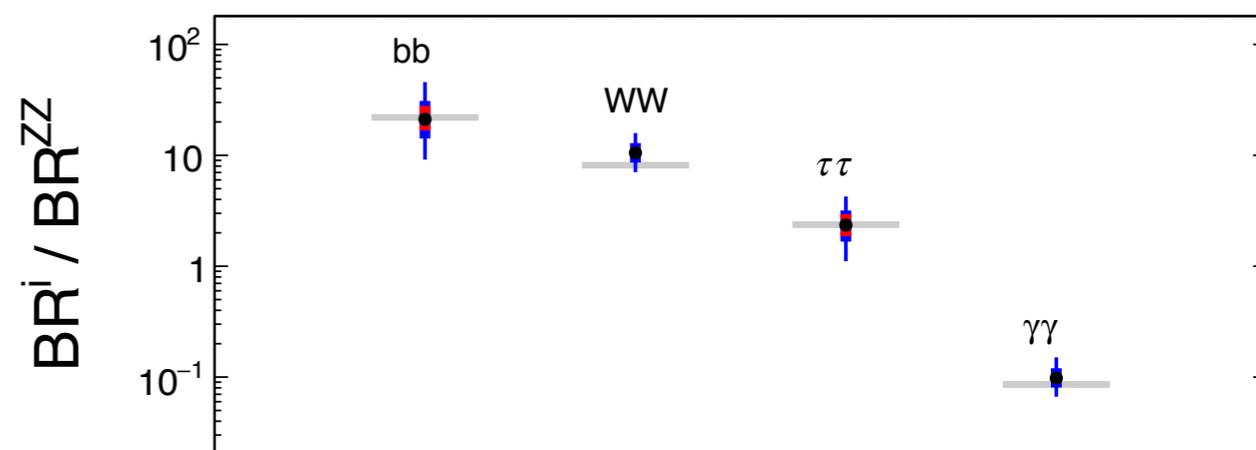

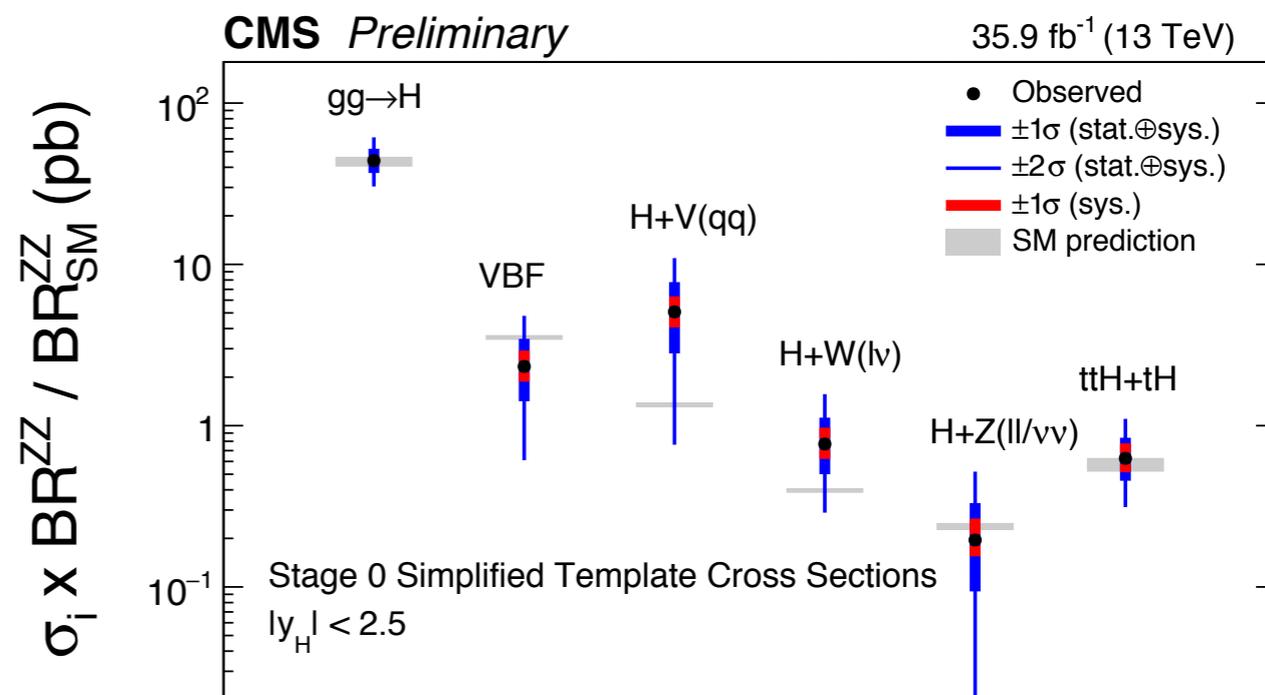

- ▶ Add direct  $H \rightarrow inv$  search channels and allow floating  $B_{inv}$  and  $B_{undet}$
- ▶ CMS+ATLAS Run-1:  
 $BR_{undet+inv} < 0.34$  (0.39 exp.)

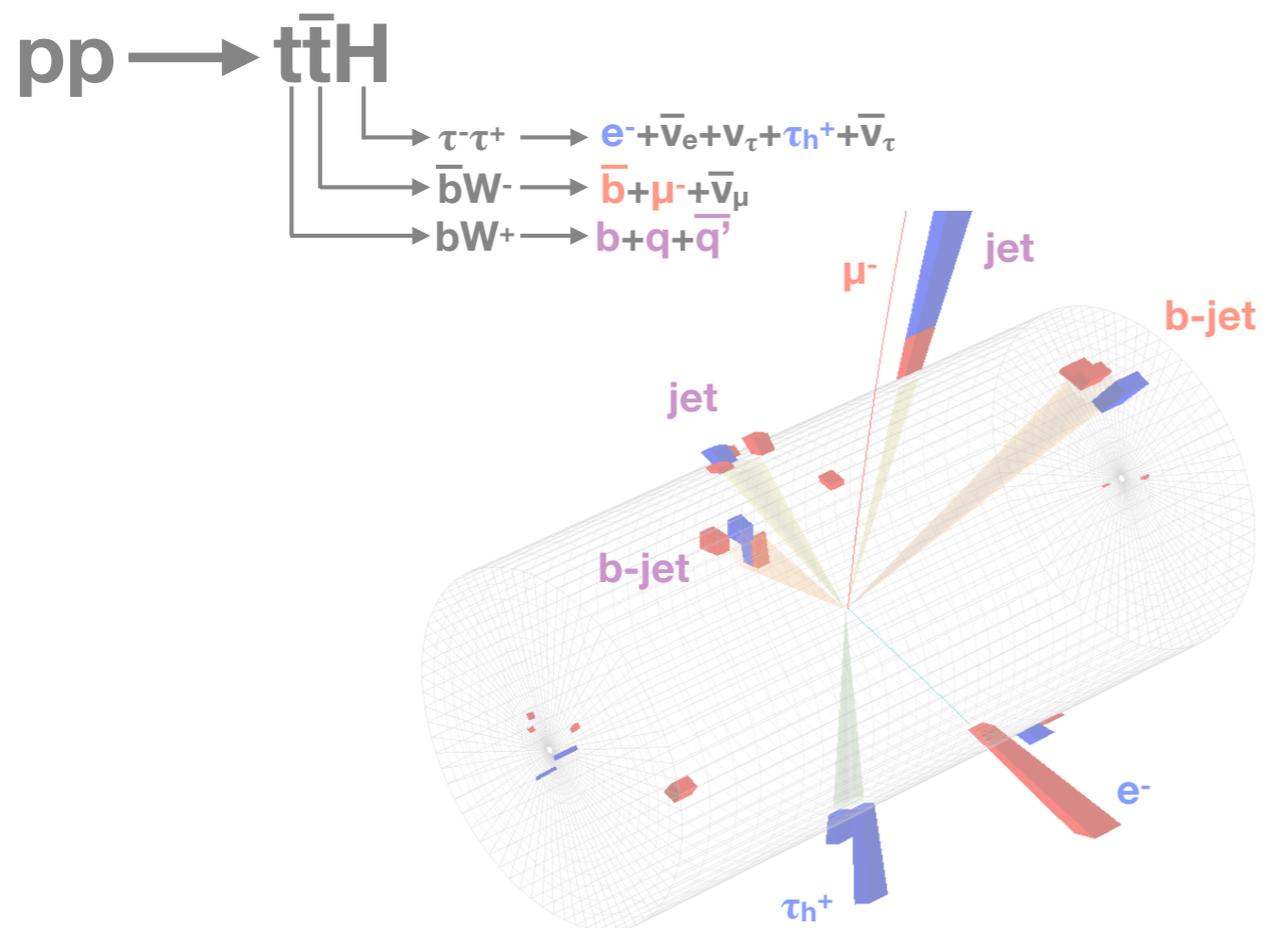

- ▶ In Run-2 CMS and ATLAS will make consistent fiducial cross section measurements (arXiv1610.07922)

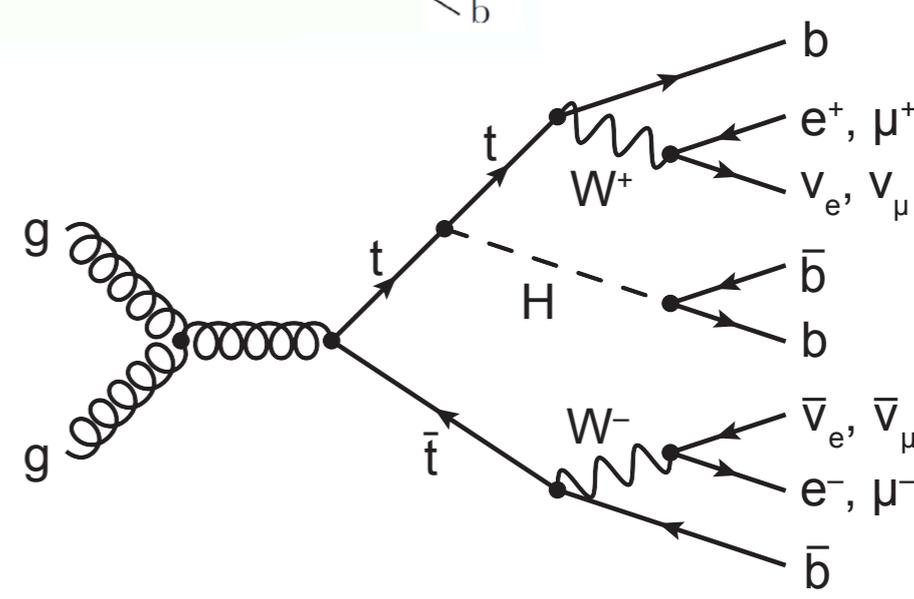

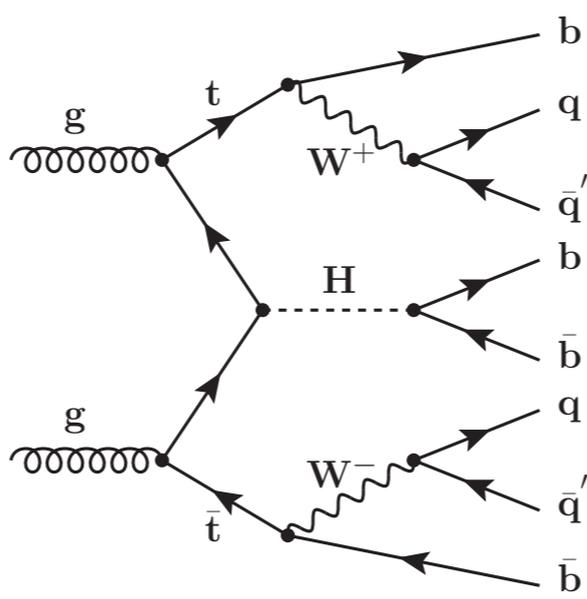

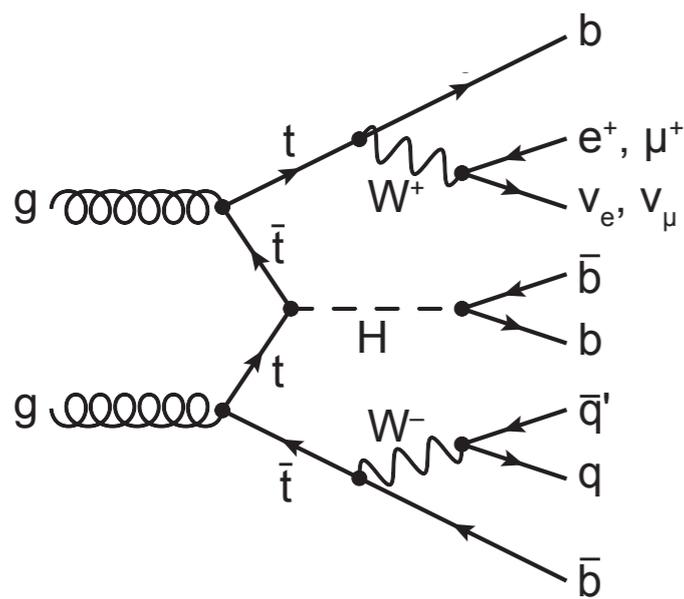

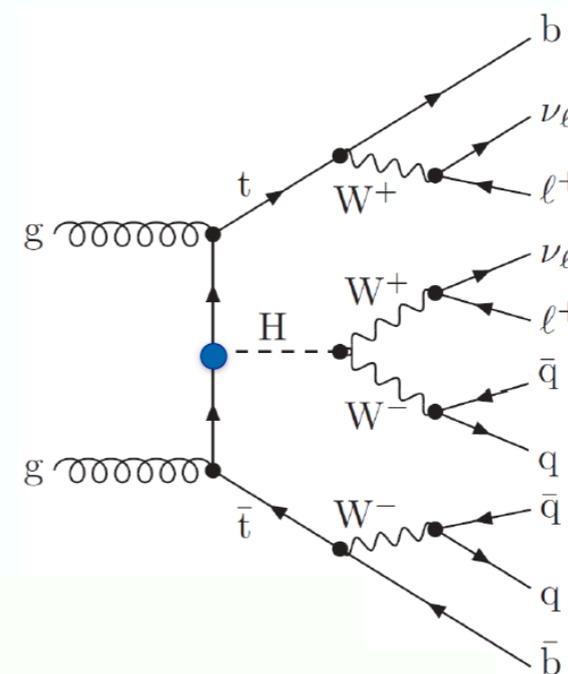

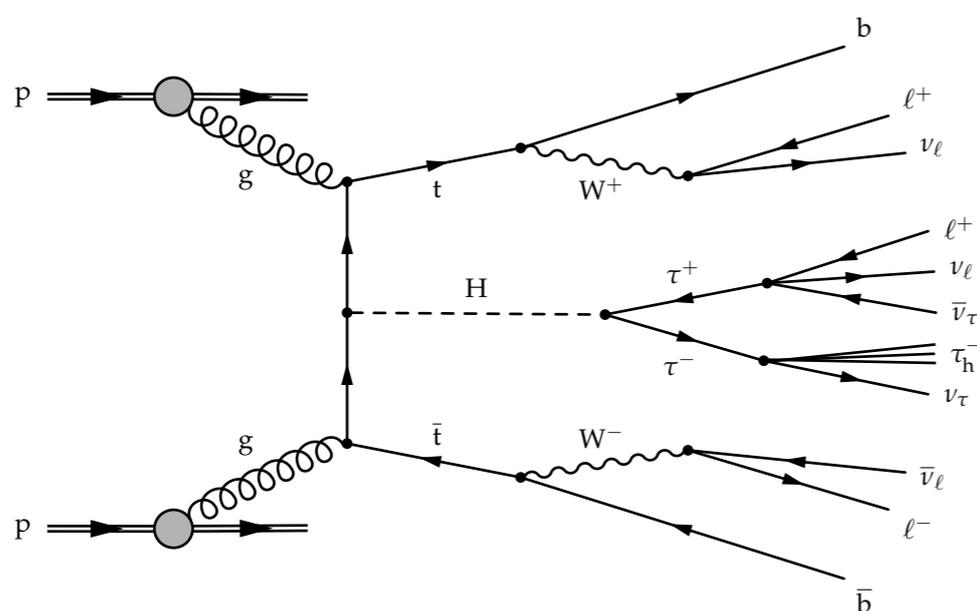

- ▶ Contrary to signal strength results, **VH split**
- ▶ One parameter for each cross section, with floating ratios of the decay BRs
- ▶ First STXS results using combination of 5 decay channels
- ▶ Inclusive **theory uncertainties** not included in the fit, shown as **uncertainty on SM prediction instead**

# Run 2 - ttH

- ▶ **ttH** production **rare in the SM** ( $\sim 1\%$  of ggF cross section)
- ▶ final state characterised by multiple jets, b-tagged jets and leptons allows for discrimination from background and increased sensitivity

- ▶ Combination of Run 1 and 2016 CMS data:

7 TeV ( $5.1 \text{ fb}^{-1}$ ), 8 TeV ( $19.7 \text{ fb}^{-1}$ ) and 13 TeV ( $35.9 \text{ fb}^{-1}$ )

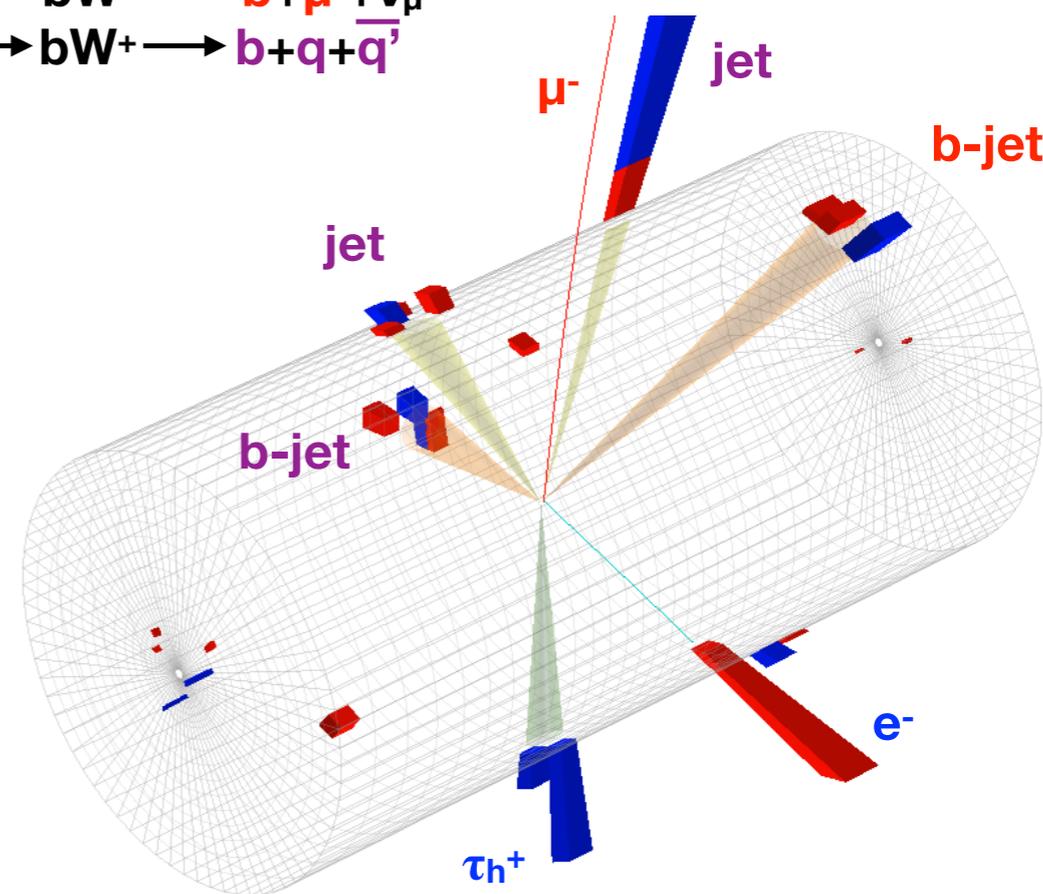

$pp \rightarrow t\bar{t}H$

$\tau^-\tau^+ \rightarrow e^- + \bar{\nu}_e + \nu_\tau + \tau_h^+ + \bar{\nu}_\tau$   
 $\bar{b}W^- \rightarrow \bar{b} + \mu^- + \bar{\nu}_\mu$   
 $bW^+ \rightarrow b + q + \bar{q}'$

- ▶ Independent analyses of several final-states topologies:

$$H \rightarrow WW^*, ZZ^*, \gamma\gamma, \tau^+\tau^-, b\bar{b}$$

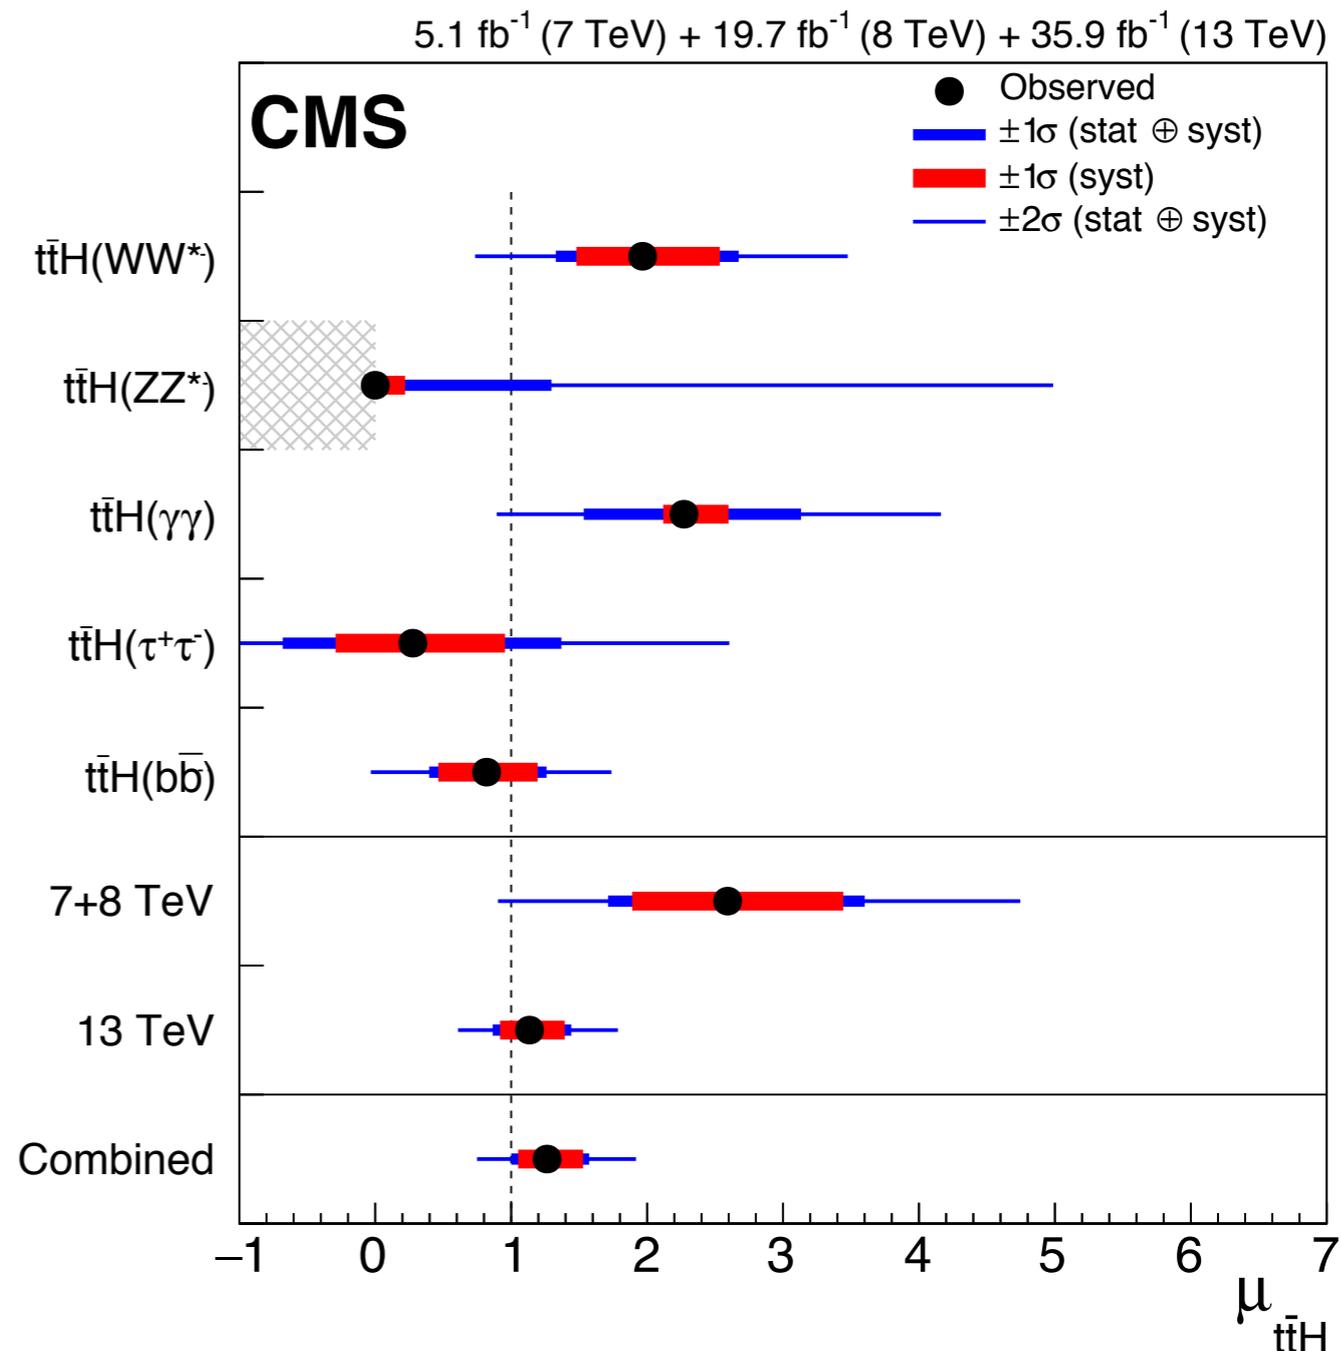

- ▶ For 7-8 TeV analysis, Higgs boson mass updated to 125.09 GeV, signal, normalisation and uncertainties updated to latest values from LHC Higgs XS WG
- ▶ Correlations between Run 1 and Run 2 studies, experimental uncertainties largely uncorrelated

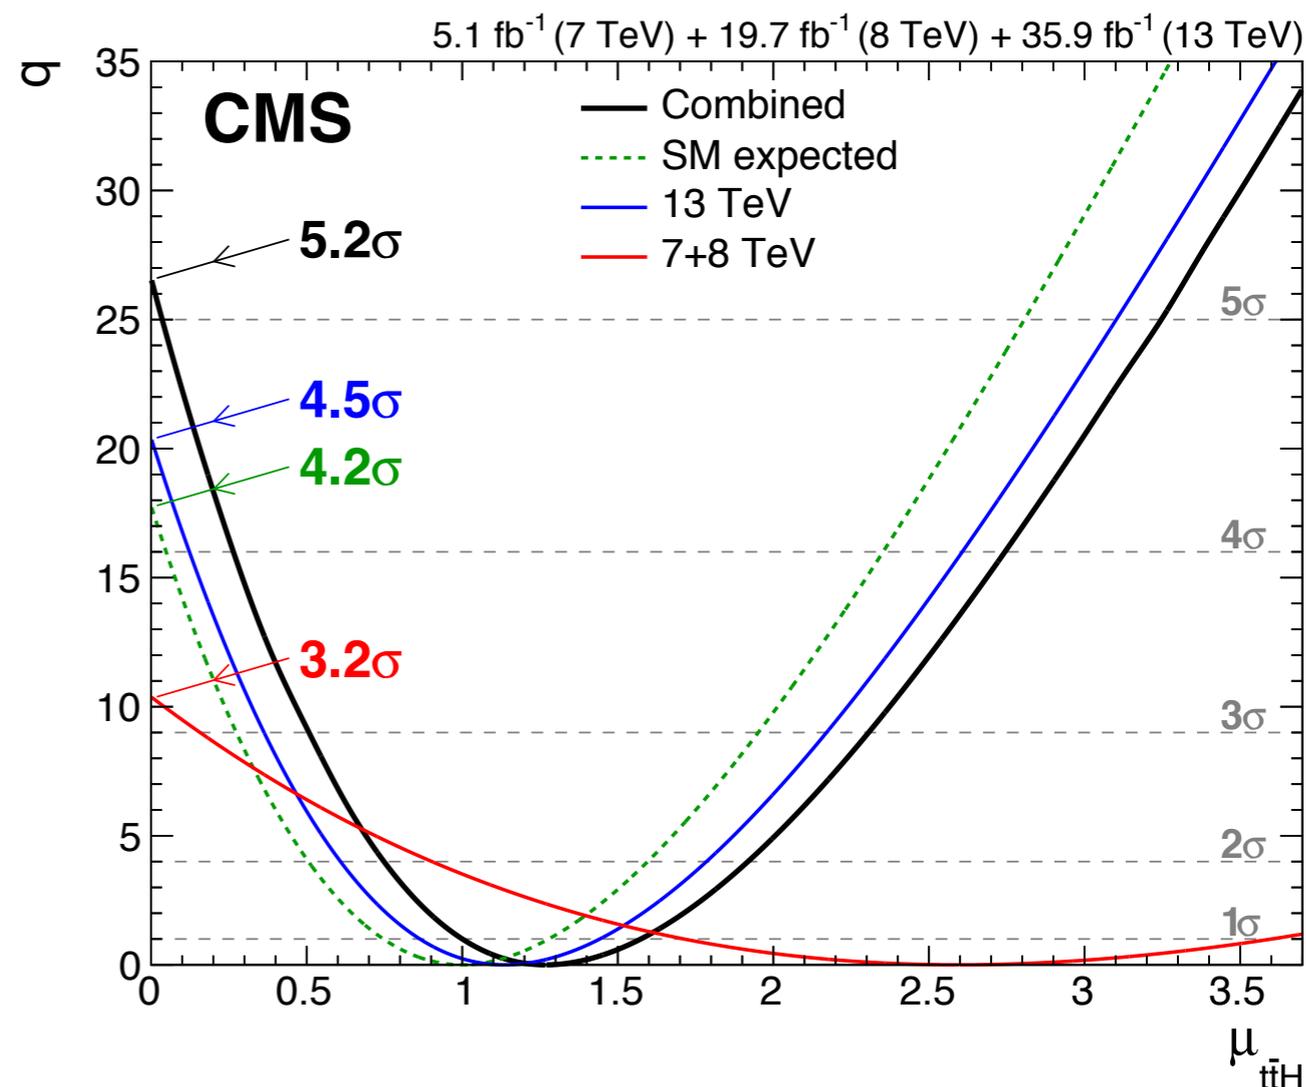

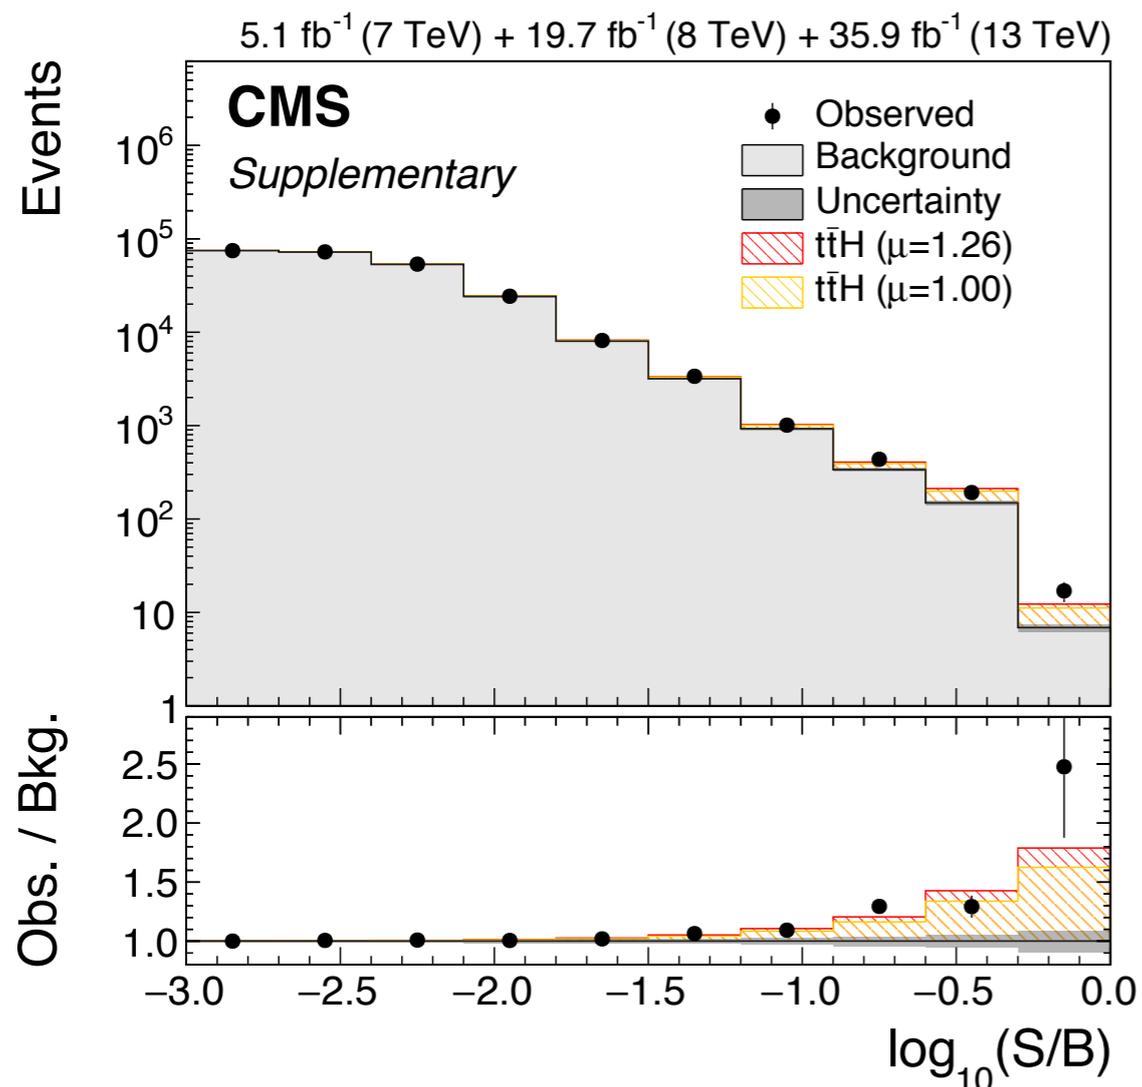

- ▶ **5 independent signal strength modifiers** for the decay channels considered, all **compatible within uncertainties**
- ▶  $tt(H \rightarrow ZZ, \gamma\gamma)$  still dominated by statistics uncertainties

$$\mu_{t\bar{t}H}$$

compatible with SM within  $1\sigma$

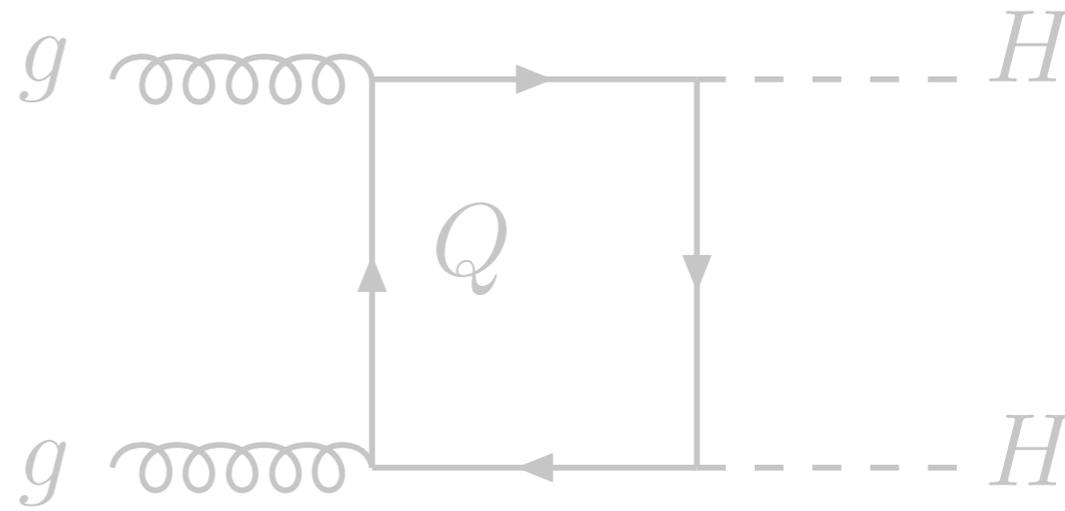

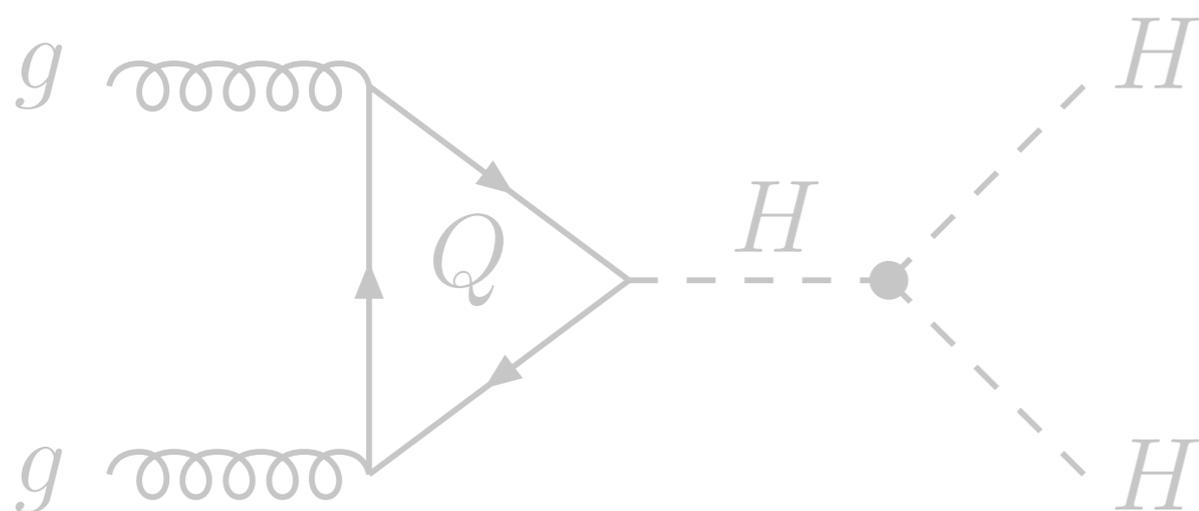

$$\mu_{t\bar{t}H} = 1.26^{+0.31}_{-0.26} = 1.26^{+0.16}_{-0.16}(\text{stat.})^{+0.17}_{-0.15}(\text{exp.})^{+0.14}_{-0.13}(\text{bkg.th.})^{+0.15}_{-0.07}(\text{sig.th.})$$

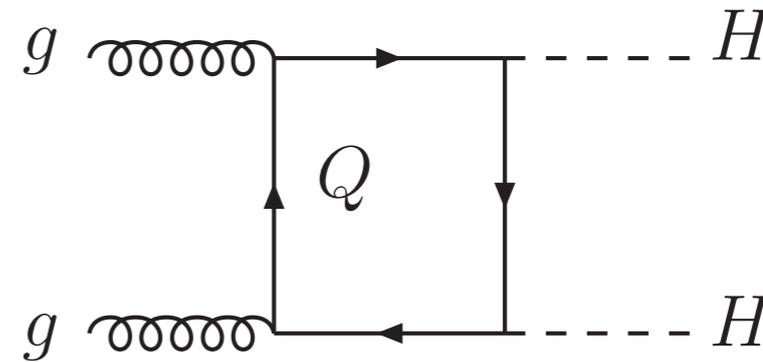

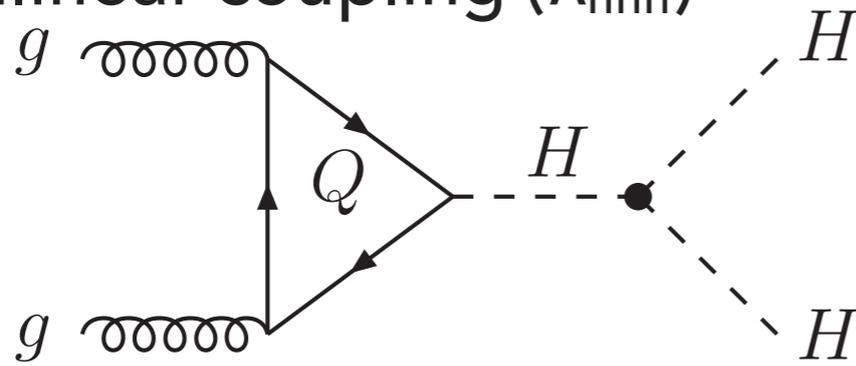

- ▶ 88 event categories combined. Excess best seen in the distribution of all events as a function of log<sub>10</sub>(S/B).
- ▶ **Clear excess** in the most signal-sensitive bins
- ▶ Observed significance is **5.2σ** (4.2σ exp.)

**First observation of the ttH production**

# Run 2 – HH Combination

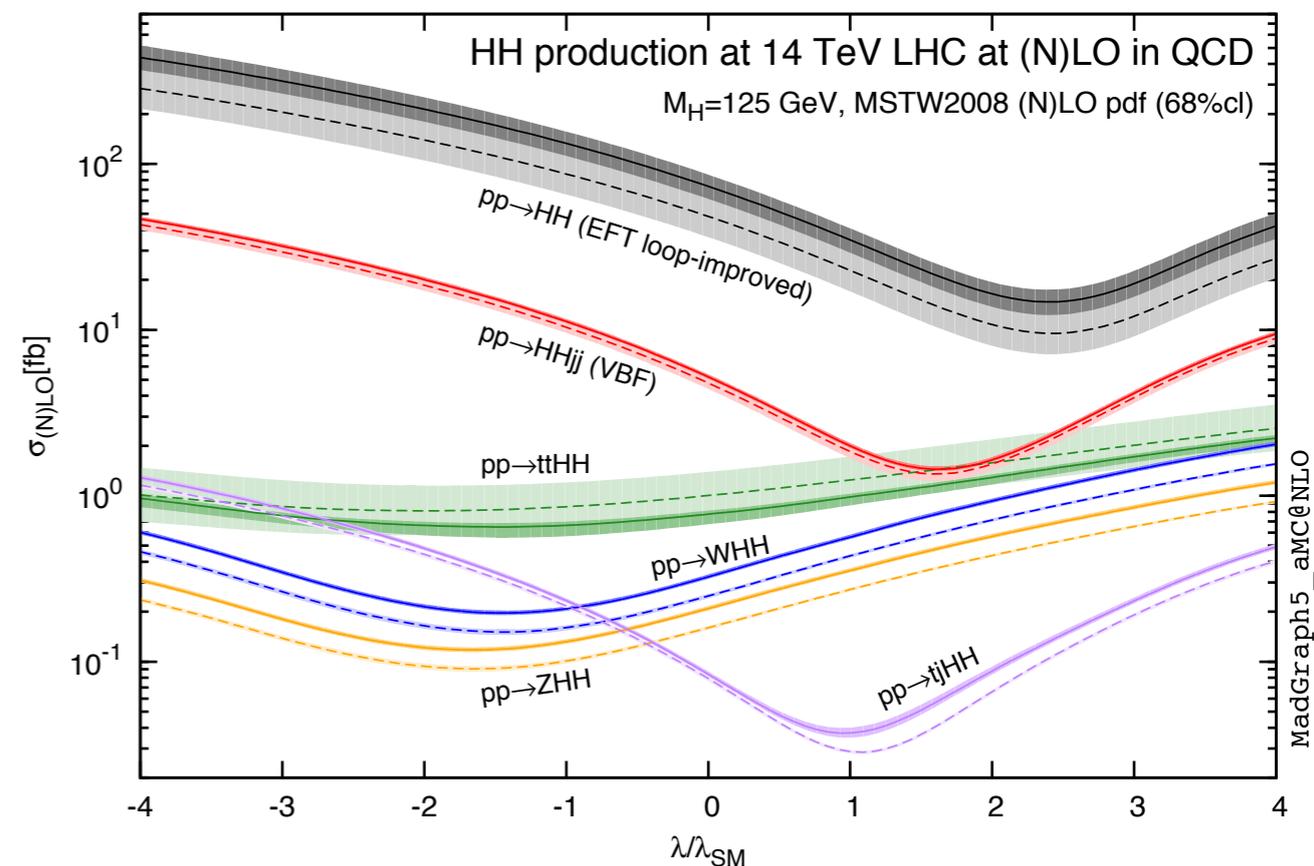

- ▶ Double Higgs production is the principal way to extract info about the Higgs trilinear coupling ( $\lambda_{hhh}$ )

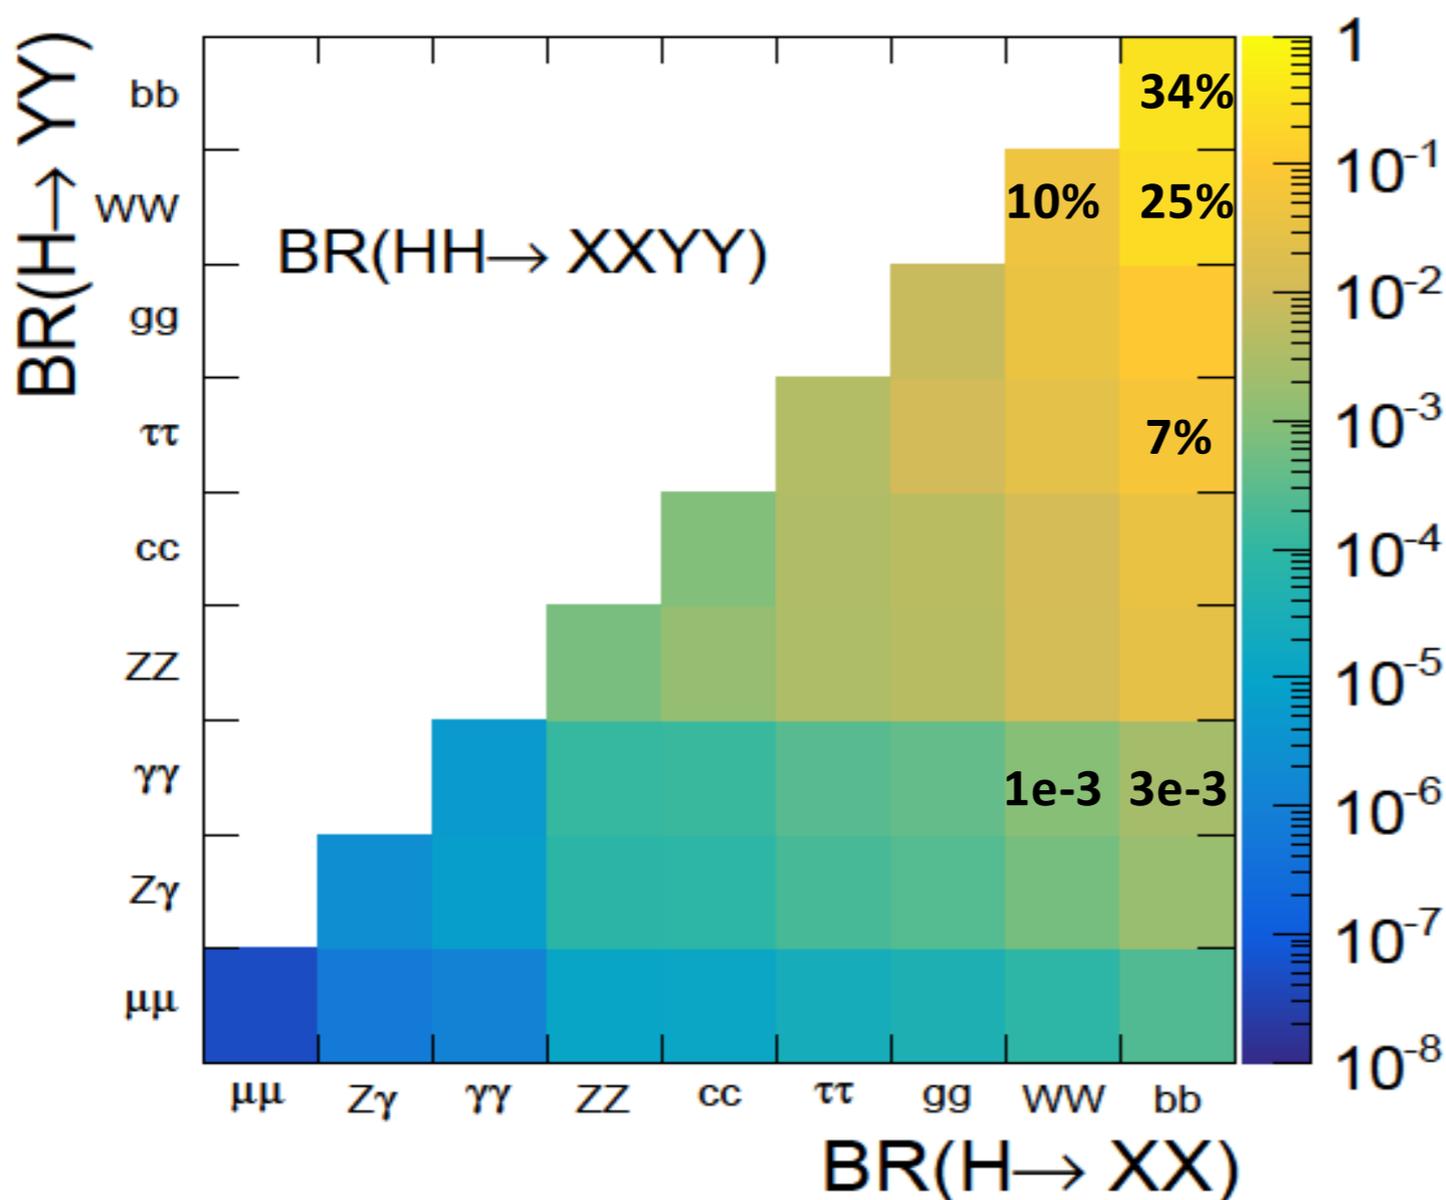

$$\sigma_{HH}^{SM} = 33.45 \text{ fb} \begin{matrix} +4.3\% \\ -6.0\% \end{matrix} \text{ (scale unc.)} \pm 3.1\% \text{ (PDF} + \alpha_S \text{ unc)} \quad [1]$$

- ▶ Run2 will not give us enough sensitivity to measure  $\lambda_{hhh}$
- ▶ Many **BSMs** are in agreement with the measured Higgs' properties, although they predict a **different**  $\lambda_{hhh}$ 
  - ▶ BSMs could lead to an enhancement of non-resonant di-Higgs production

[1] LHCHXSWG Yellow Report 4

- ▶ Four final states used for the non-resonant combination
- ▶ Analyses performed using the full 2016 dataset ( $35.9 \text{ fb}^{-1}$ )

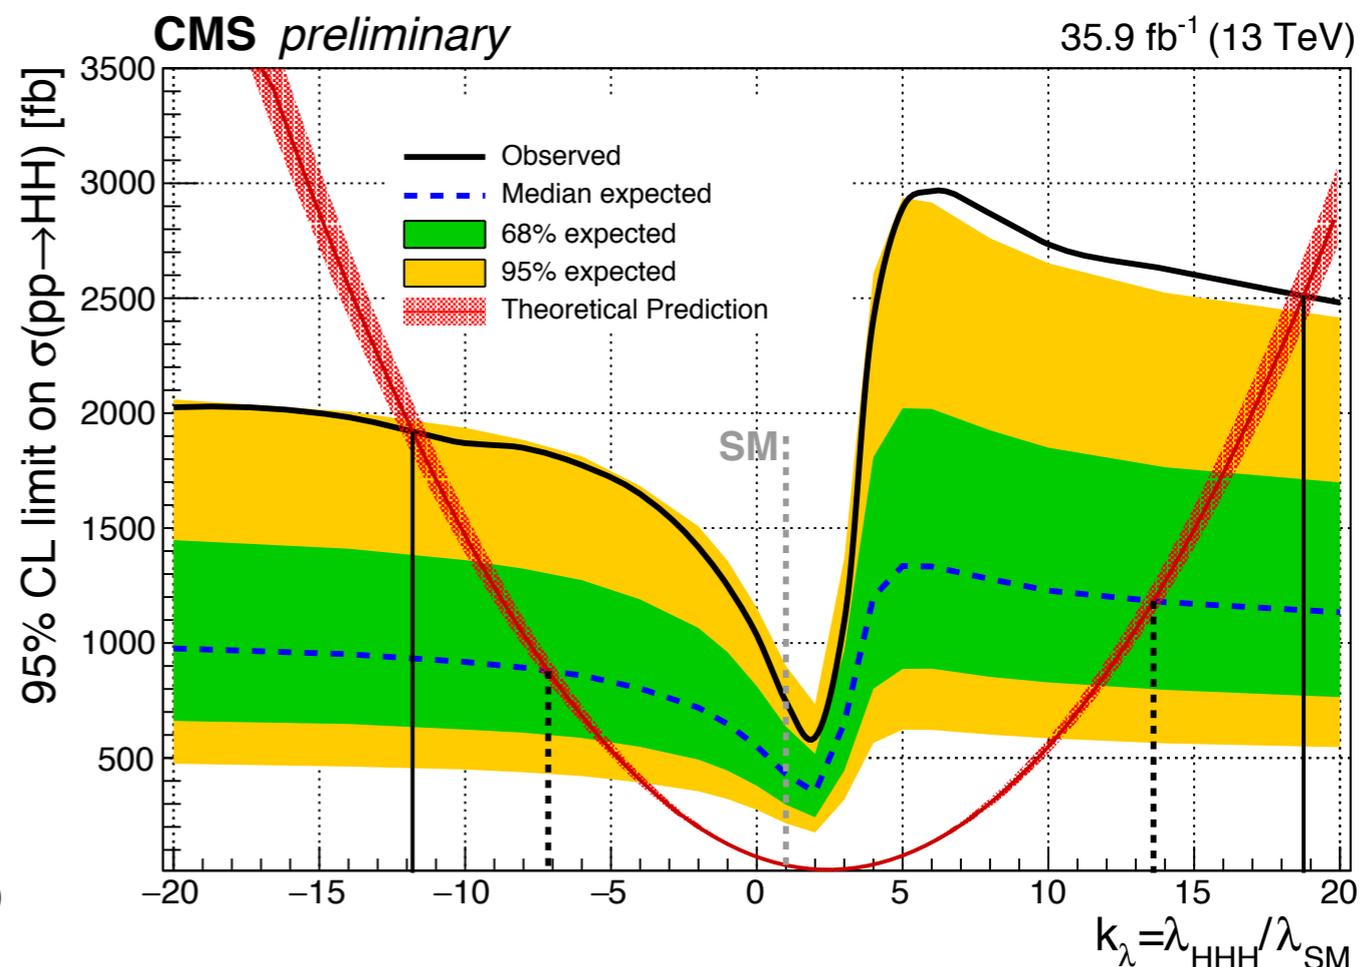

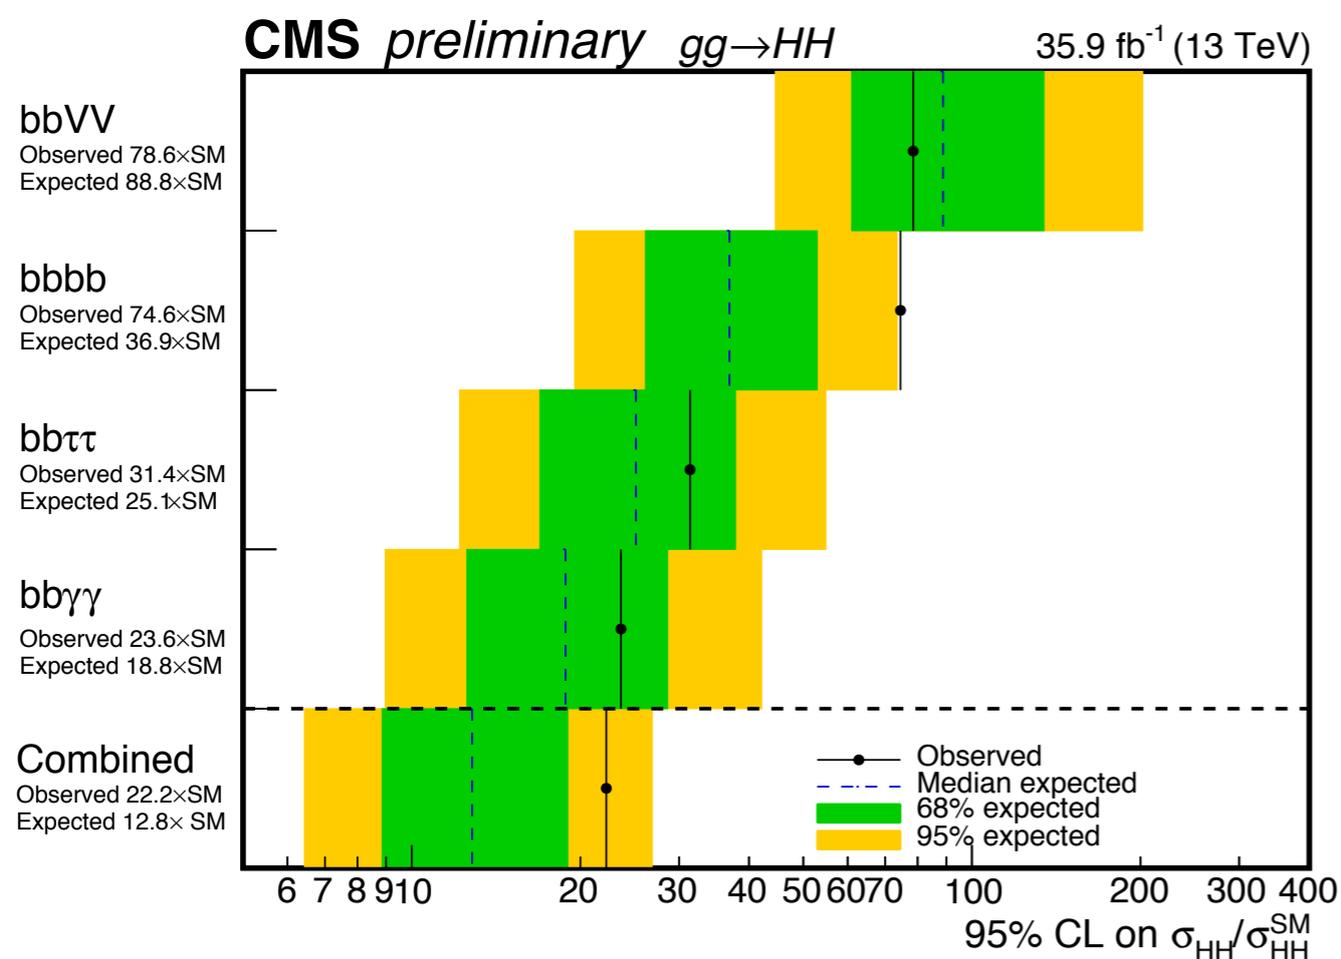

- ▶ **bb bb** : higher BR, high QCD/tt contamination
- ▶ **bb WW** : high BR, large irreducible tt
- ▶ **bb  $\tau\tau$**  : relatively low background
- ▶ **bb  $\gamma\gamma$**  : high purity, very low BR

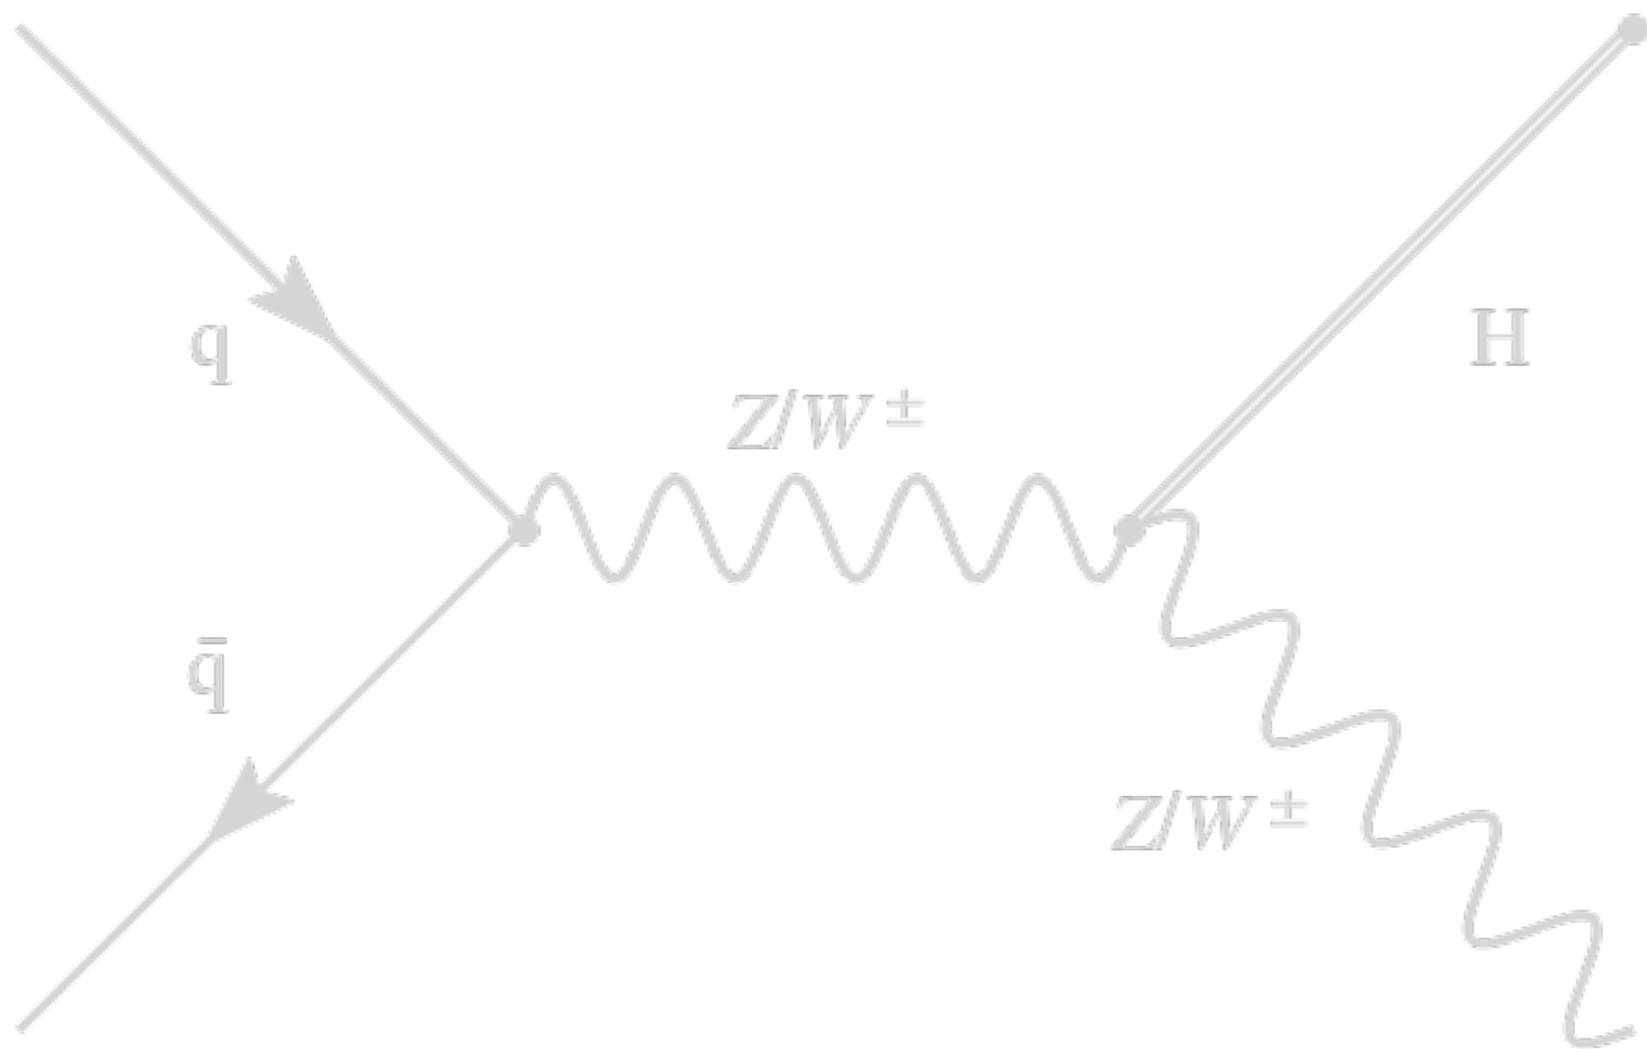

Channel	SM
$bb\gamma\gamma$	<b>24 (19)</b>
$bb\tau\tau$	<b>31 (25)</b>
$bbWW$	<b>79 (89)</b>
$bbbb$	<b>75 (37)</b>

- ▶ 450 nuisances
- ▶ 30% improvement on  $b\bar{b}\gamma\gamma$  result alone for SM.
- ▶ The upper limit observed (expected) at 95% CL on the production cross section is

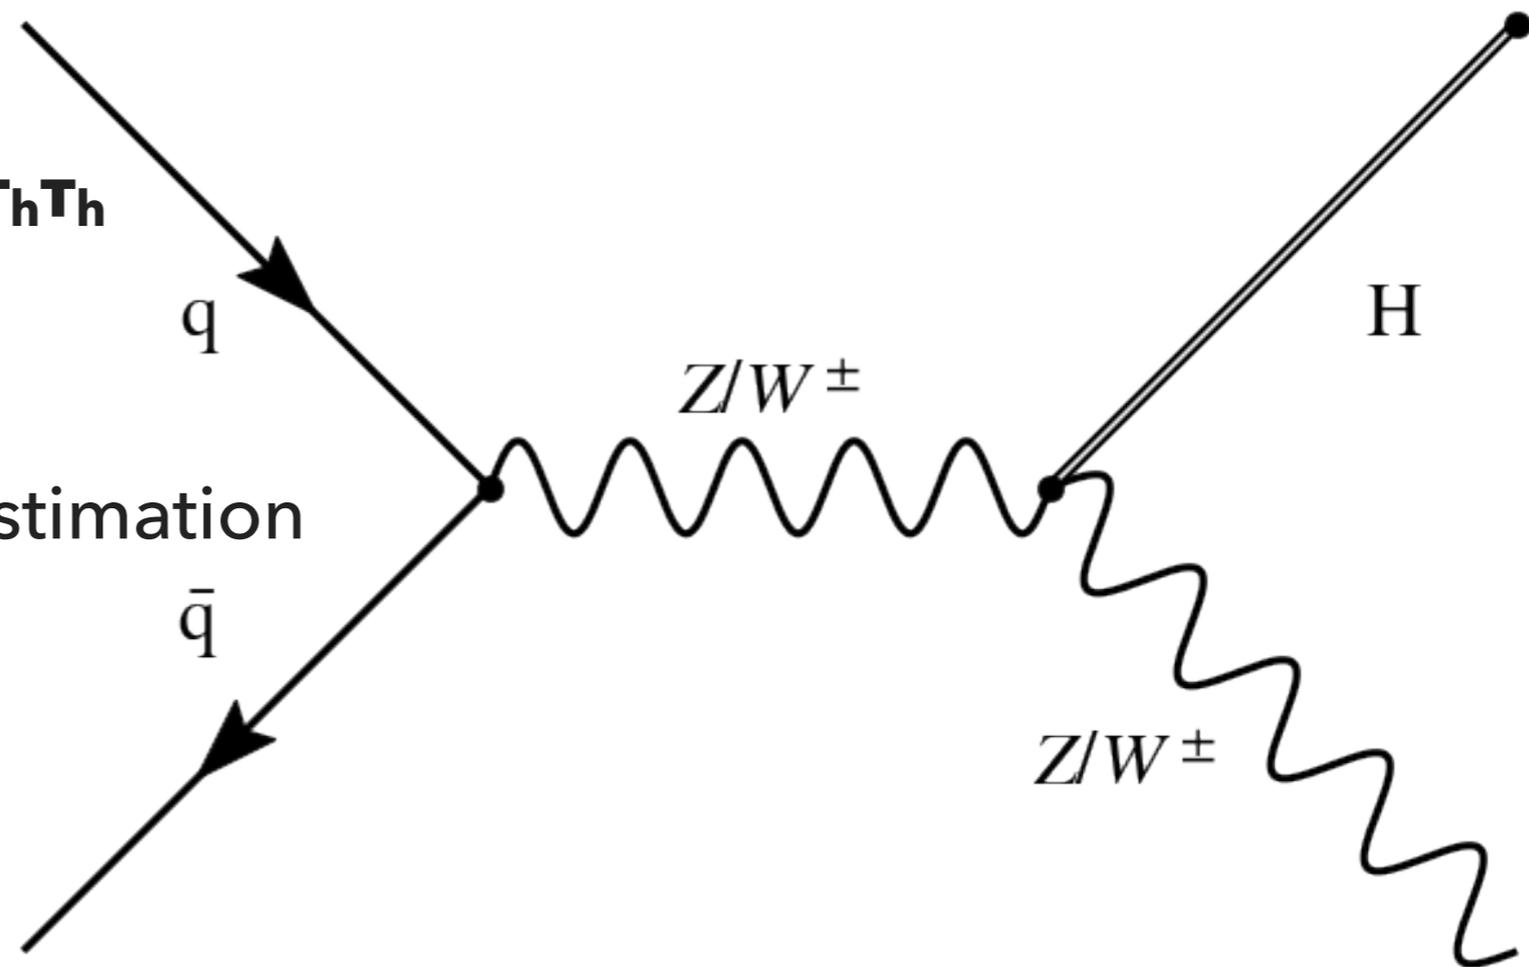

$$\sigma_{HH} = 21.8 (12.4) \times \sigma_{HH}^{SM}$$

# Run 2 - VH( $\rightarrow \tau\tau$ )

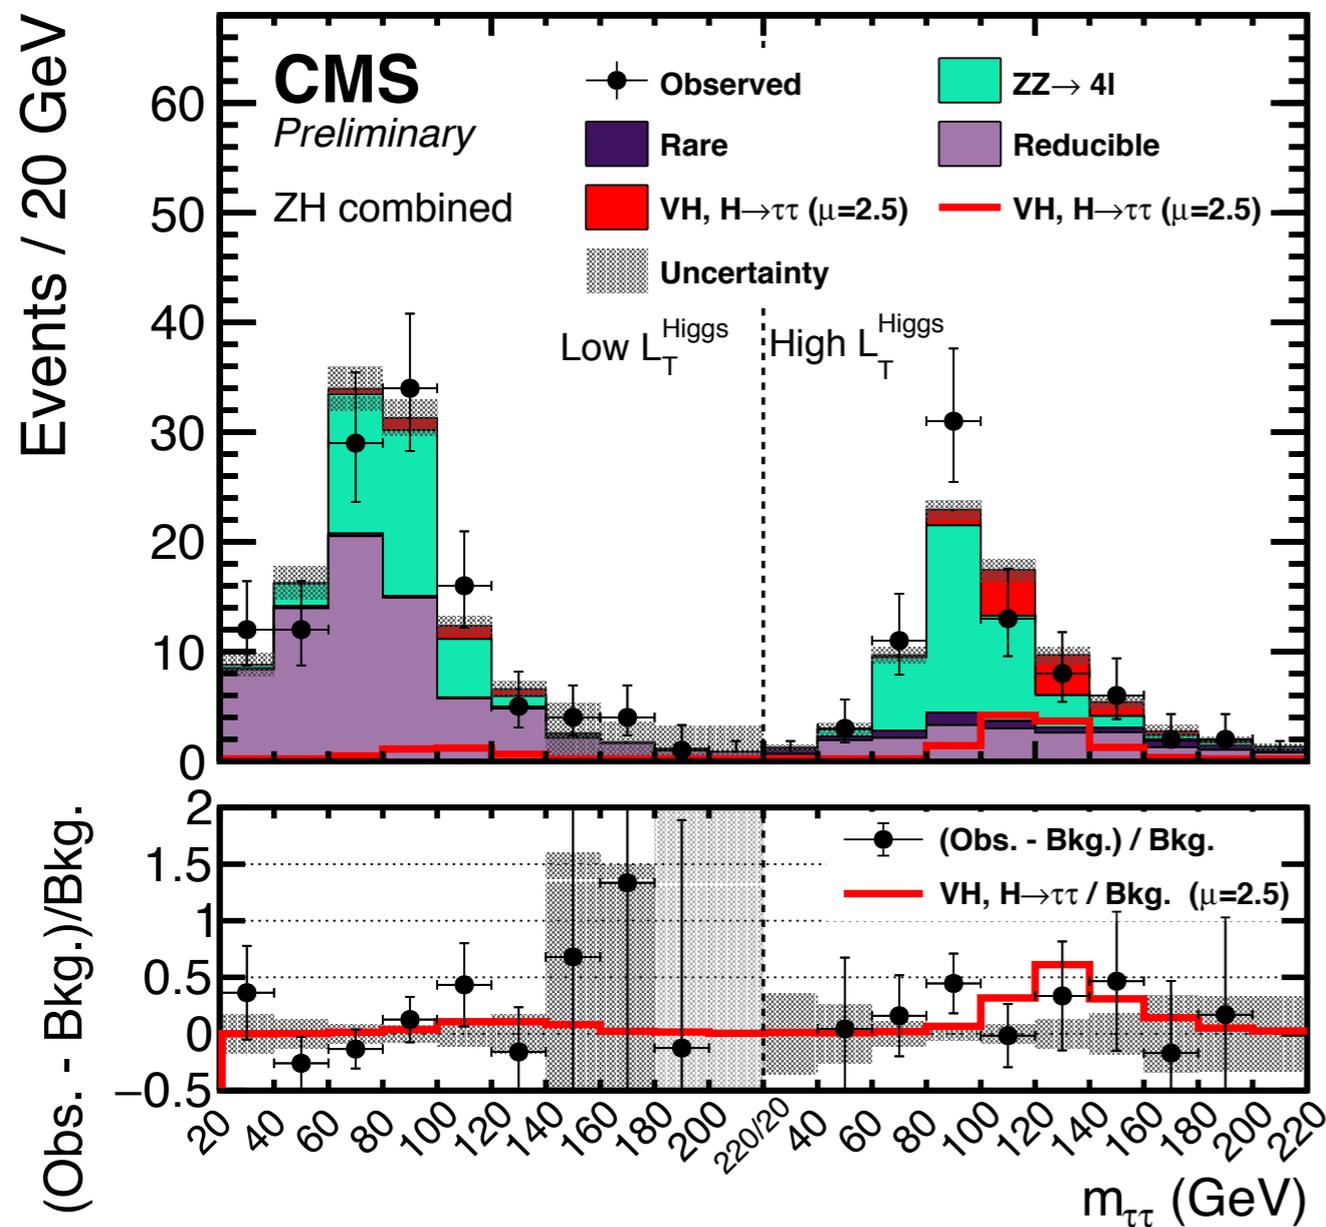

- ▶ VH production allows **directly and independently probe WH** and **ZH couplings**
- ▶ The  $H\rightarrow\tau\tau$  decay is the second most sensitive channel to establish VH production. It is the last missing piece for 2016 grand combination
- ▶ Multiple final states depending on decay mode of vector bosons and tau leptons ( $l = e, \mu$ )
  - ▶ WH semi-leptonic:  $l\mu\tau_h, l\tau_h\tau_h$
  - ▶ ZH:  $lle\mu, lle\tau_h, ll\mu\tau_h, ll\tau_h\tau_h,$
- ▶ Data-Driven technique for estimation of fake contribution

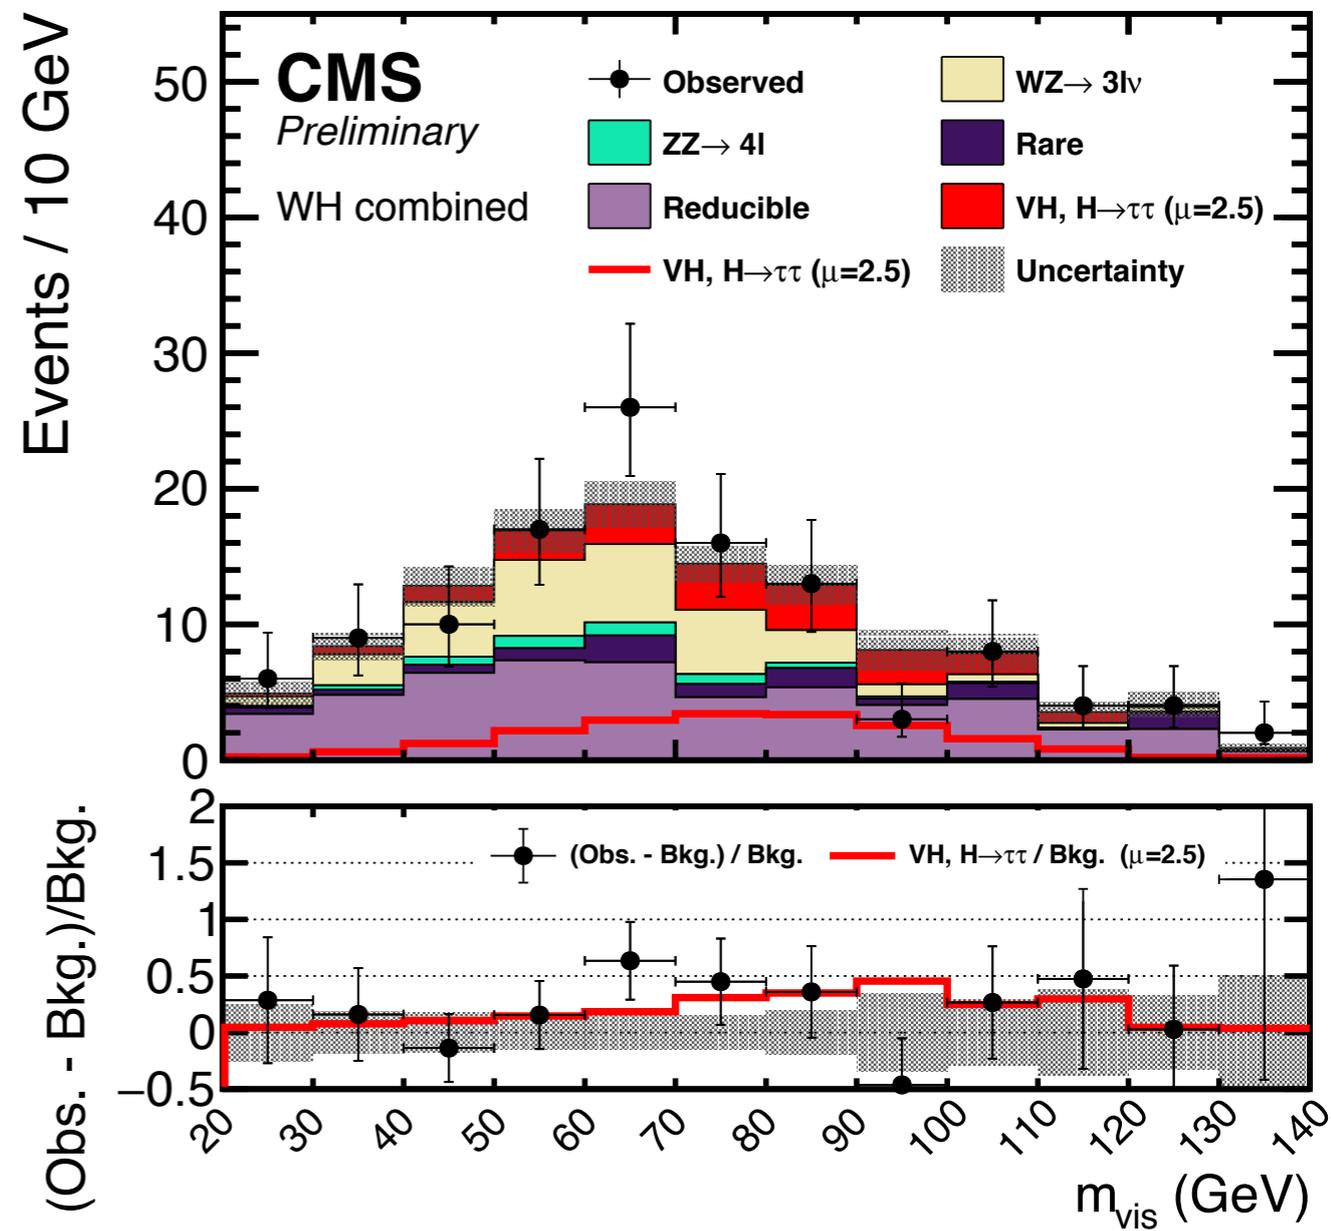

## ZH

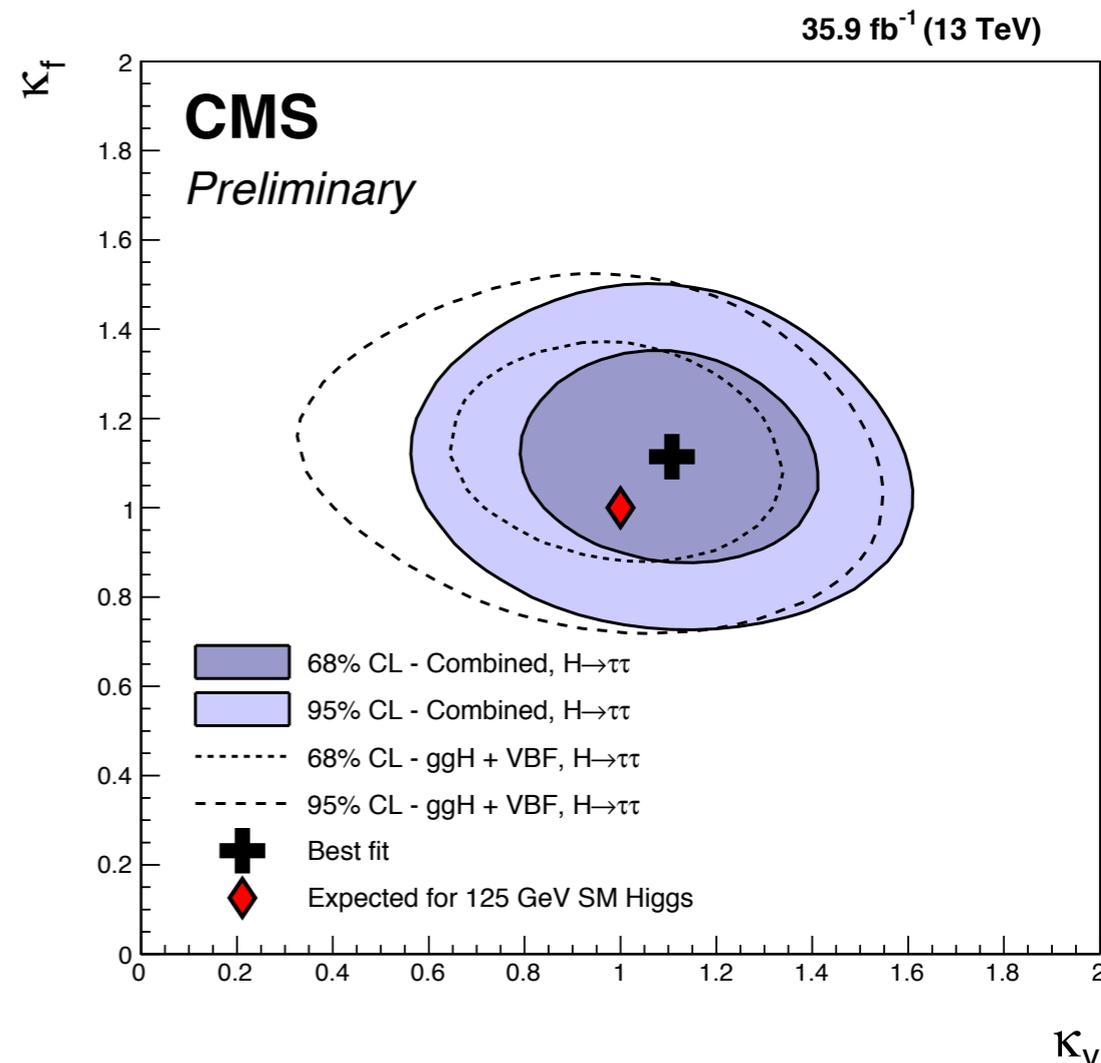

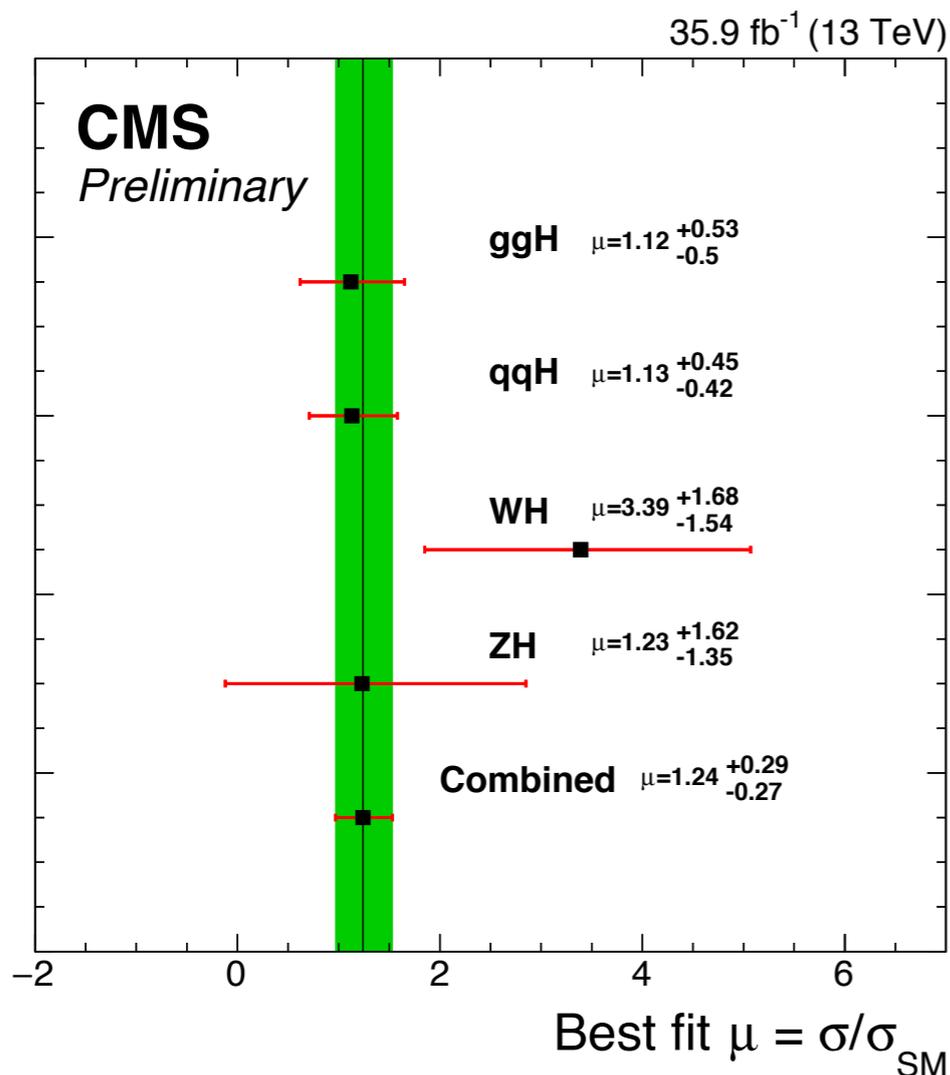

35.9 fb<sup>-1</sup> (13 TeV)

## WH

35.9 fb<sup>-1</sup> (13 TeV)

- ▶ The best-fit signal strength for VH

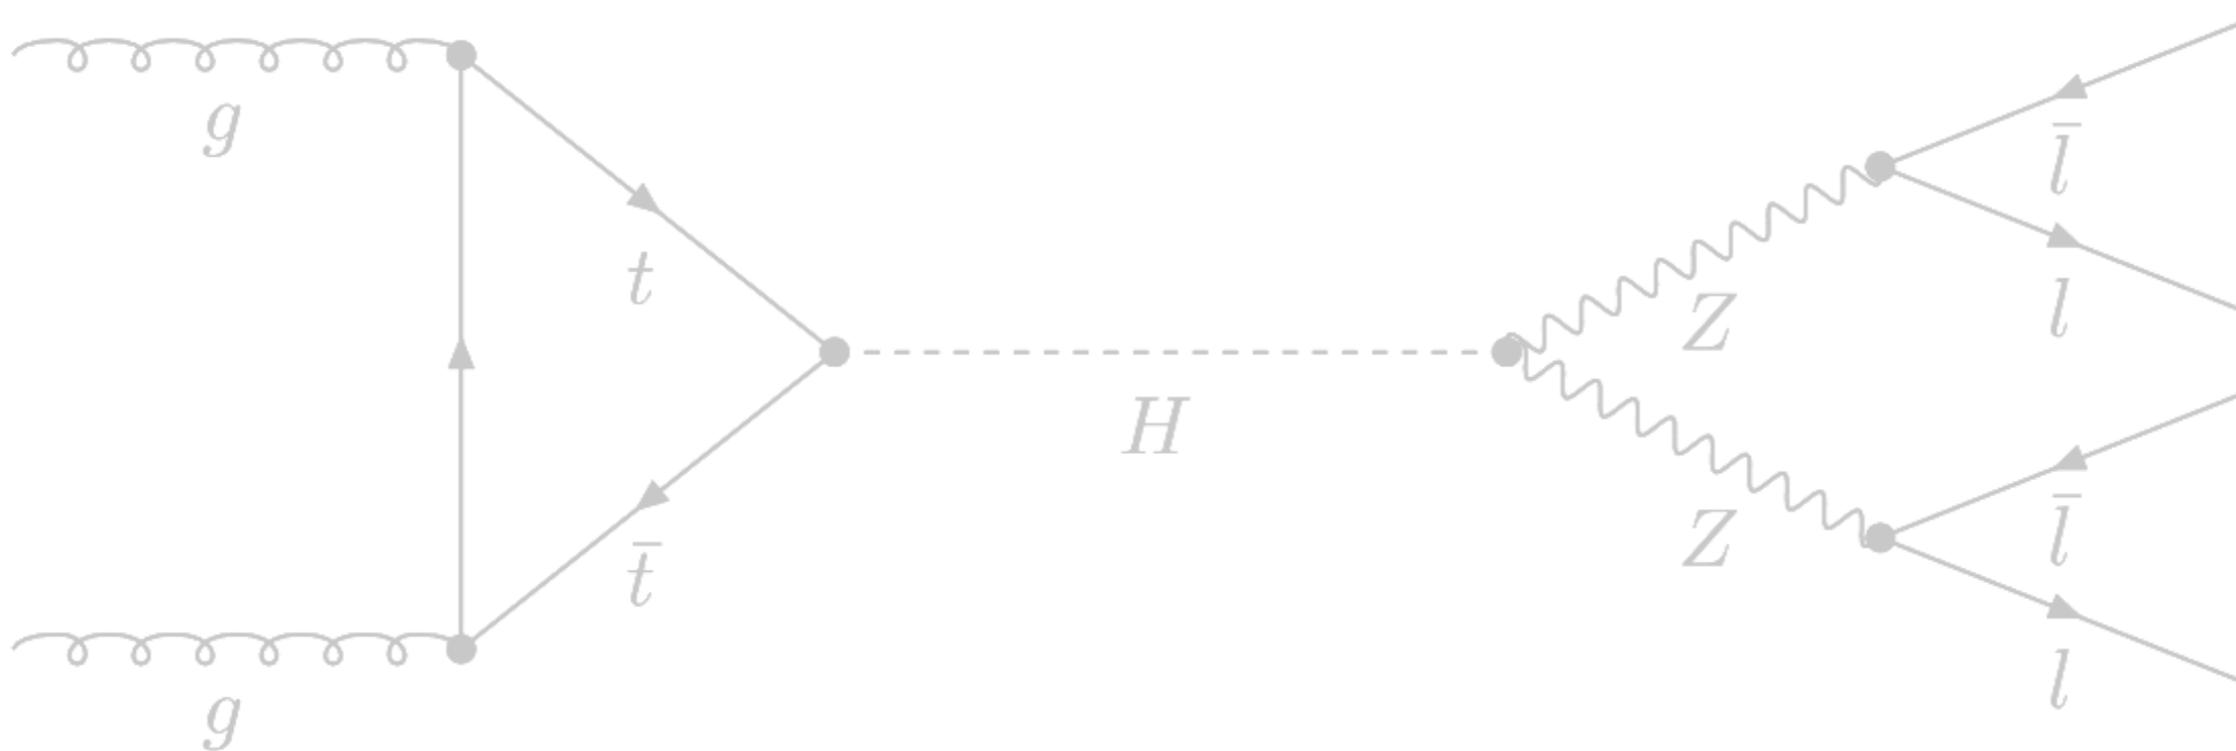

$$\mu = 2.54_{-1.26}^{+1.35} (\mu = 1.0_{-0.97}^{+1.08} \text{ exp.})$$

- ▶ Combining with ggH( $\tau\tau$ ) and VBF-H( $\tau\tau$ ) observed signal strength is

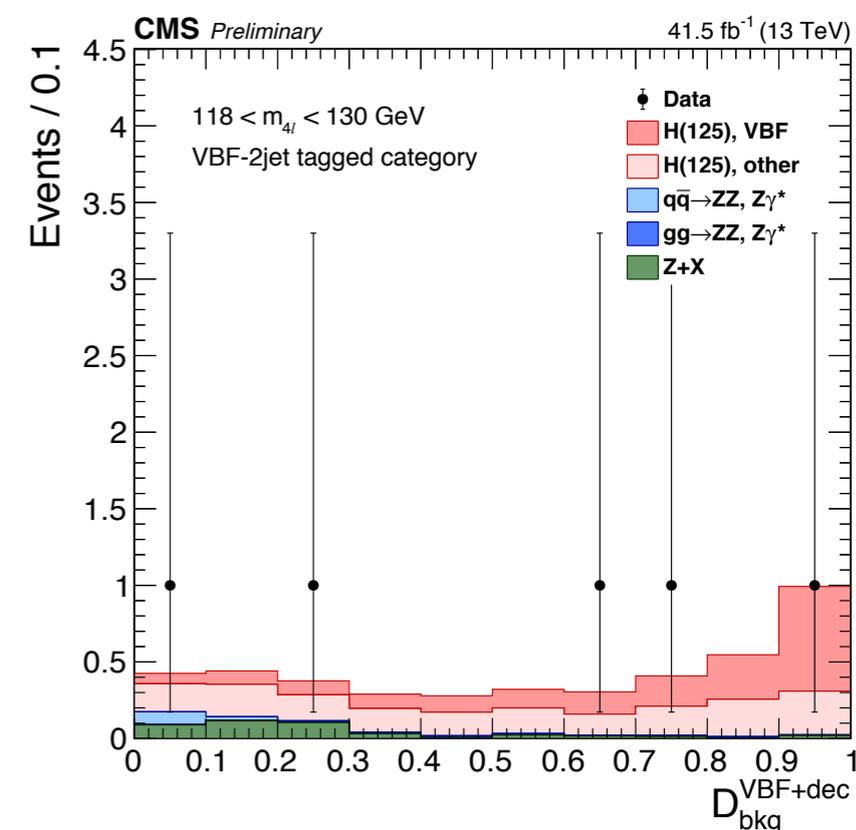

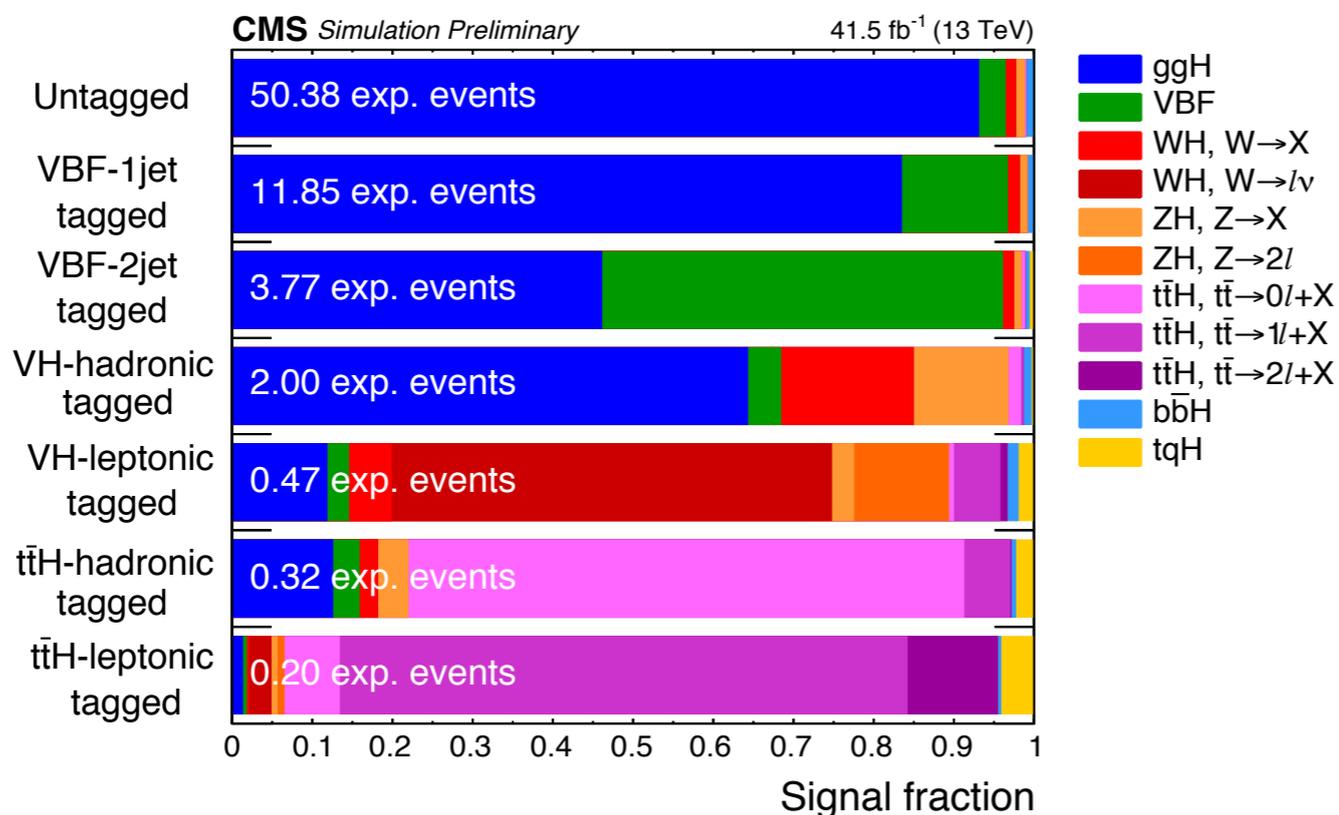

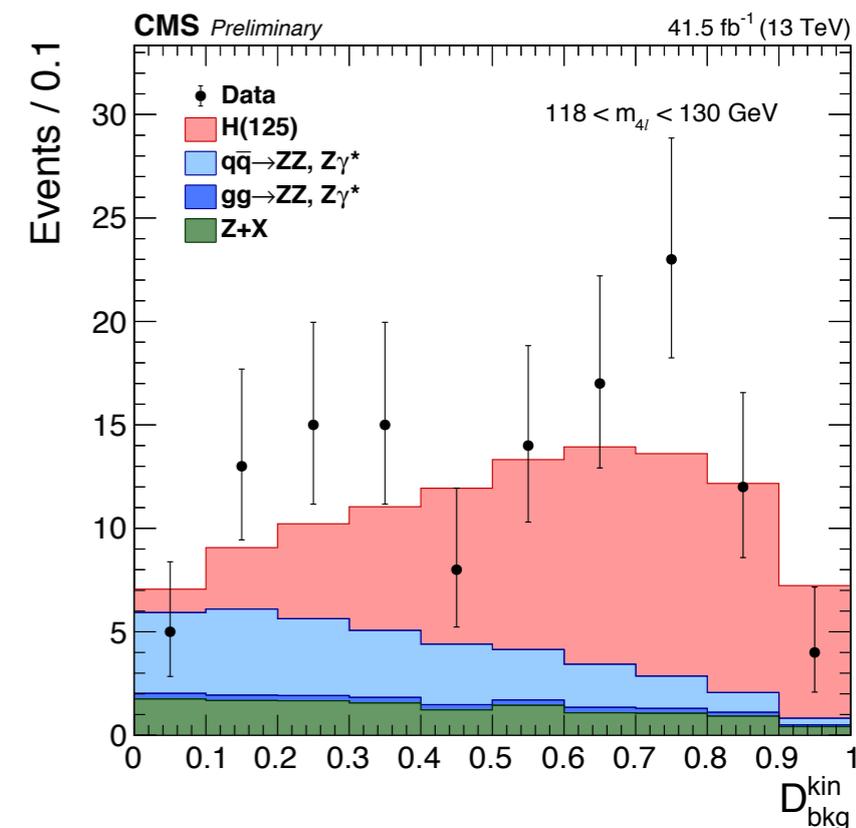

$$\mu = 1.24_{-0.27}^{+0.29}$$

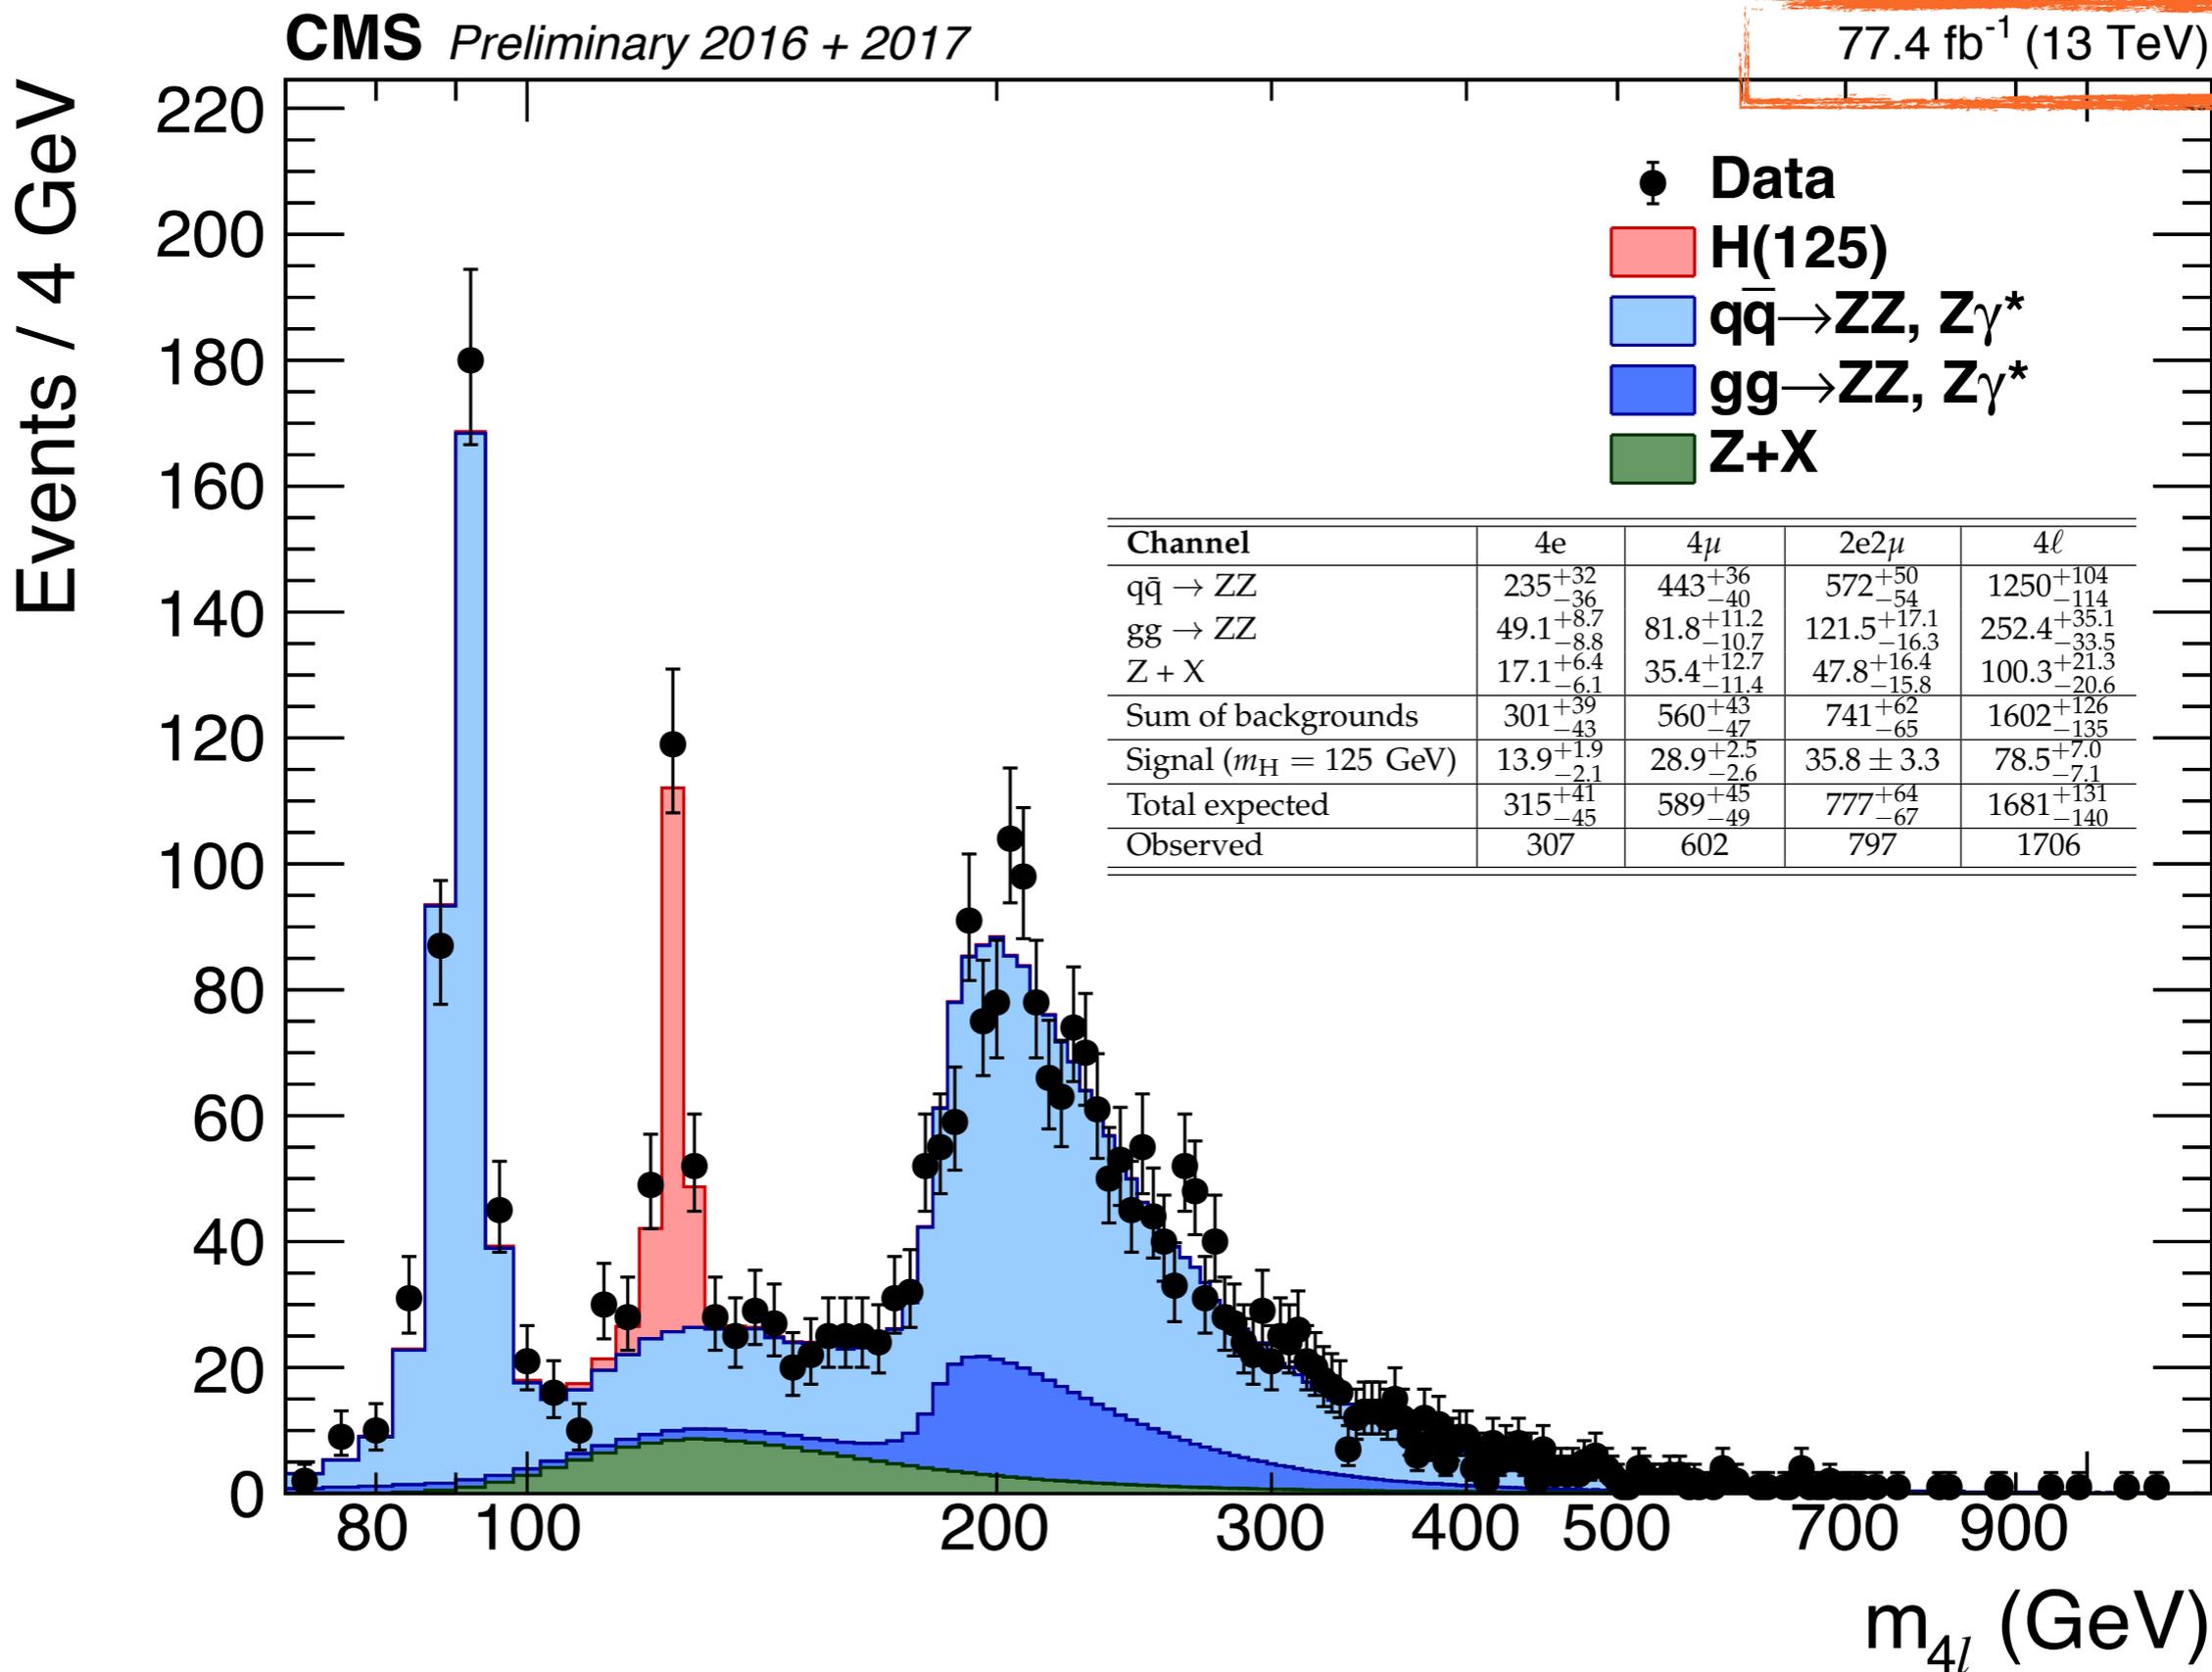

- ▶  $k_V$ - $k_F$  scan for  $m_H = 125.09$  GeV.
- ▶ Combination VH, ggH and VBF with H( $\tau\tau$ )
  - ▶ ggH+VBF dashed lines
- ▶ Better constrain on  $k_V$

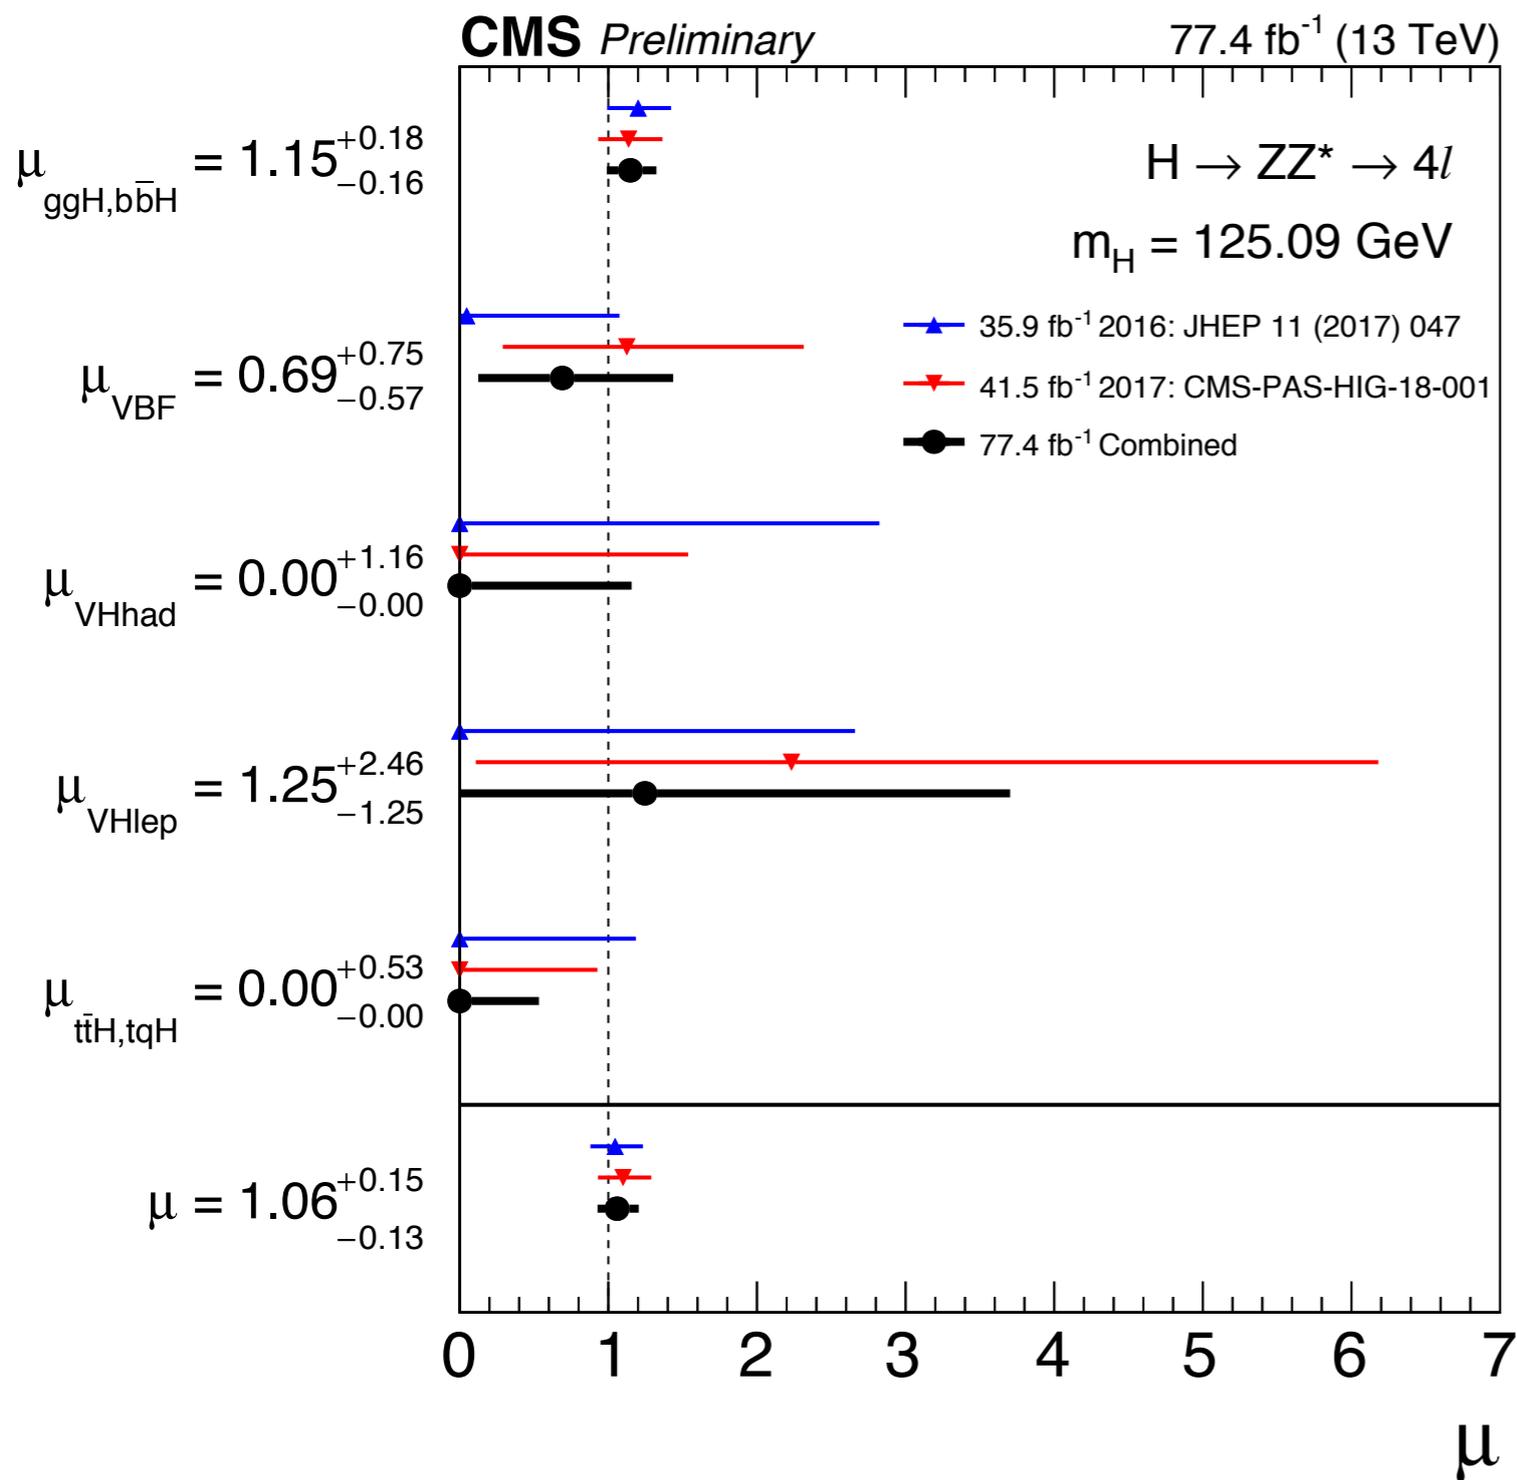

# $H \rightarrow ZZ^* \rightarrow 4l$ (2017 dataset)

- ▶ Low signal rate, but very clear signal topology over a small, flat background (mainly  $qqZZ$ ,  $Z$ +jets)
- ▶ 4 isolated leptons in final state combined in 2 Z pairs
- ▶ Kinematical information (matrix element KD discriminants) to separate signal and backgrounds and categorised the events

► Improvement for VBF production

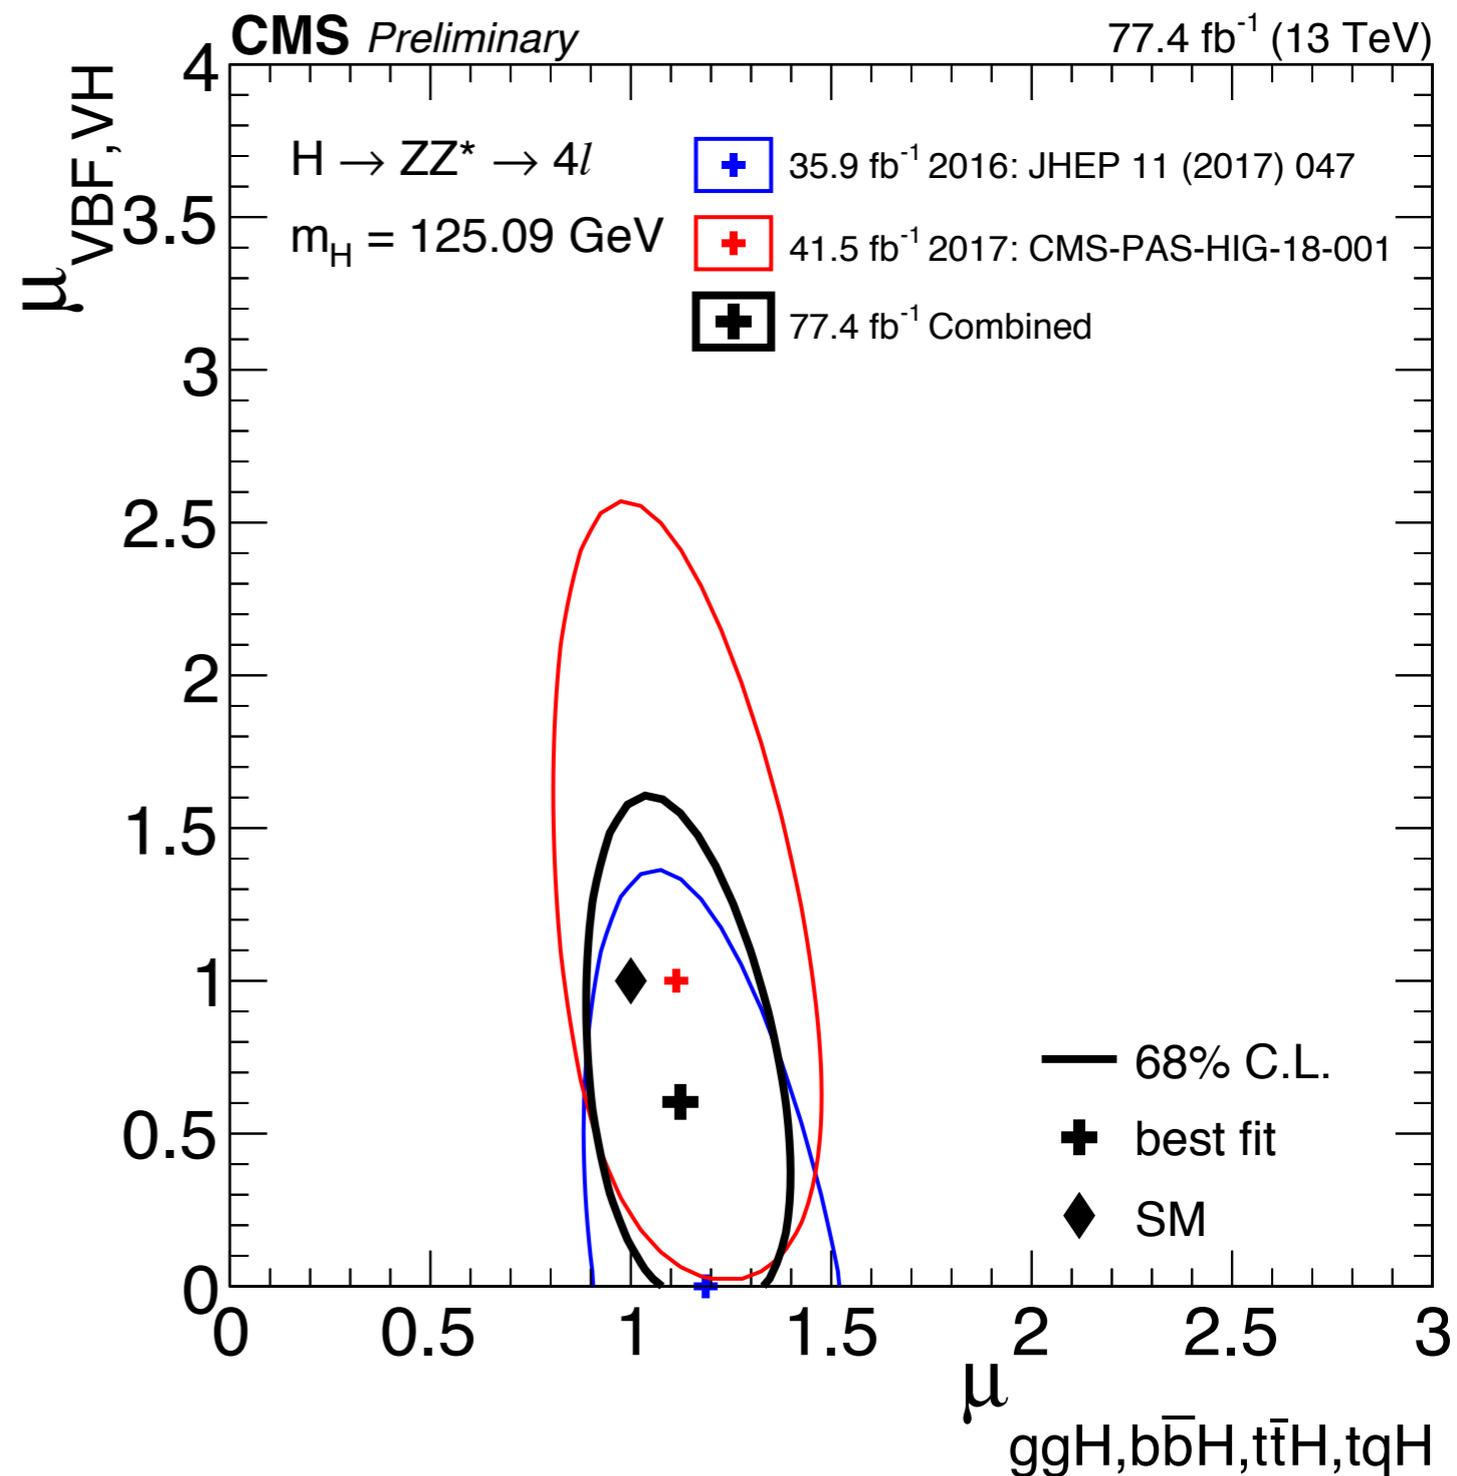

► The measured signal strength modifier is

$$\mu = 1.10^{+0.19}_{-0.17}$$

► Signal strength modifier combining 2016+2017 is:

$$\mu = 1.06^{+0.15}_{-0.13}$$

- ▶ Measurements of signal strength modifiers associated with fermions and vector bosons are performed
- ▶ Better coverage in the 2017 analysis
- ▶ Improvement performing the combination

# Conclusions

- ▶ From the **Run 1 data**, all **Higgs boson properties** are **consistent** with the expectations from the **standard model**
- ▶ A **combination** of all the results in the various Higgs boson channels can be **used to determine the Higgs boson couplings** to other particles.
- ▶ The **Run 2 data significantly improve** the **precision** of the Higgs measurement performed during Run 1 and the **sensitivity** on the most rare processes.
  - ▶ ttH production is the channel that gains the most from the increased collision energy (Observation)
- ▶ With the **Run 2 full dataset** (around  $150 \text{ fb}^{-1}$ ) the sensitivity of the **analyses dominated by statistical errors** will significantly **improve**.

Thank you for your attention

- Summary of how all production and decay processes scale as a function of the  $k$  parameters:

Production	Loops	Interference	Effective scaling factor	Resolved scaling factor
$\sigma(\text{ggH})$	✓	b – t	$\kappa_g^2$	$1.04 \cdot \kappa_t^2 + 0.002 \cdot \kappa_b^2 - 0.038 \cdot \kappa_t \kappa_b$
$\sigma(\text{VBF})$	–	–		$0.73 \cdot \kappa_W^2 + 0.27 \cdot \kappa_Z^2$
$\sigma(\text{WH})$	–	–		$\kappa_W^2$
$\sigma(\text{qq/qg} \rightarrow \text{ZH})$	–	–		$\kappa_Z^2$
$\sigma(\text{gg} \rightarrow \text{ZH})$	✓	Z – t		$2.46 \cdot \kappa_Z^2 + 0.47 \cdot \kappa_t^2 - 1.94 \cdot \kappa_Z \kappa_t$
$\sigma(\text{ttH})$	–	–		$\kappa_t^2$
$\sigma(\text{gb} \rightarrow \text{WtH})$	–	W – t		$2.91 \cdot \kappa_t^2 + 2.40 \cdot \kappa_W^2 - 4.22 \cdot \kappa_t \kappa_W$
$\sigma(\text{qb} \rightarrow \text{tHq})$	–	W – t		$2.63 \cdot \kappa_t^2 + 3.58 \cdot \kappa_W^2 - 5.21 \cdot \kappa_t \kappa_W$
$\sigma(\text{bbH})$	–	–		$\kappa_b^2$
Partial decay width				
$\Gamma^{ZZ}$	–	–		$\kappa_Z^2$
$\Gamma^{WW}$	–	–		$\kappa_W^2$
$\Gamma^{\gamma\gamma}$	✓	W – t	$\kappa_\gamma^2$	$1.59 \cdot \kappa_W^2 + 0.07 \cdot \kappa_t^2 - 0.67 \cdot \kappa_W \kappa_t$
$\Gamma^{\tau\tau}$	–	–		$\kappa_\tau^2$
$\Gamma^{bb}$	–	–		$\kappa_b^2$
$\Gamma^{\mu\mu}$	–	–		$\kappa_\mu^2$
Total width for $\text{BR}_{\text{BSM}} = 0$				
$\Gamma_H$	✓	–	$\kappa_H^2$	$0.58 \cdot \kappa_b^2 + 0.22 \cdot \kappa_W^2 + 0.08 \cdot \kappa_g^2 +$ $+ 0.06 \cdot \kappa_\tau^2 + 0.026 \cdot \kappa_Z^2 + 0.029 \cdot \kappa_c^2 +$ $+ 0.0023 \cdot \kappa_\gamma^2 + 0.0015 \cdot \kappa_{Z\gamma}^2 +$ $+ 0.00025 \cdot \kappa_s^2 + 0.00022 \cdot \kappa_\mu^2$

- ▶ The measured signal strength modifier is  $\mu = 1.10^{+0.19}_{-0.17}$
- ▶ Measurements of signal strength modifiers associated with fermions and vector bosons are performed

- ▶ significance of 2.3 standard deviations (1.0 expected)
- ▶ Combining this analysis with the analysis  $ggH(\tau\tau)$  and VBF- $H(\tau\tau)$  observed significance is 5.5 standard deviations (4.8 expected)
