

Cleaning Blowup

L.R. Carver, X. Buffat

08/09/17

Introduction

- In past presentations it has been shown that the injection cleaning causes a strong kick to circulating bunches.
- Typically seen (with nominal 25ns beam, 96-144bpi) to occur around the 5th or 6th batch injection.
- Strong correlation with the cleaning. Shown below is before and after cleaning in B2H is switched on. Happens in both beams.
- Does it have an impact on emittance?

Emittance

- Does it have an impact on emittance?
- Yes but by a small amount. Difficult to see when viewing BSRT vs bunch slot as it blends in with other blown up bunches.

Causes

- Possible causes? Excitation amplitude follows an approximate ecloud shape on B2, (B1 would depend on ecloud + beambeam)
- For plot on right, fills with emittance blowup from cleaning are in red. Fills without are in blue.
- For 8b4e the emittance blowup is still present but smaller.
- How is the ADT witness region implemented? Possibly a kick on all bunches but only the ones with lower ADT gain react.
