# Table of Contents

## 1 Introduction

Description of optics measurement methods  
Limitations of the existing methods

## 2 Optics-based-calibration

## 3 Approaches for optics-based-BPM calibration

Disconnecting key quadrupoles from the lattice  
Analysis of normalized dispersion.

## 4 Conclusions

## $\beta$ function from Turn by Turn data.

- BPM records the position every time the particle pass through it. The pick up is recording a sinusoidal signal as a function of the turn number.
- The BPM readout is affected by the calibration factor ( $C_i$ ).
- The oscillations recorded by the BPMs are a superposition of beam betatron oscillations and induced betatron excitations.

$$x_{i,N} = C_i \sqrt{2J\beta_d} \sin(Q_d \cdot N + \Phi_i) \Rightarrow \beta_{x,y} = \frac{A_i^2}{2J_{x,y} C_i^2} \quad (1)$$

## From Fourier Transformation to $\beta$ from amplitude (II): Action calculation

- Action can be computed either using the amplitude of the main line of the spectrum recorded by all the BPMs or by a subset of BPMs (assuming that for a set of BPMs  $\sum_i^{N_{\text{set}}} \approx N_{\text{set}} C_i^2$ )

$$2J_{x,y} = \frac{1}{N} \sum_i^N \frac{(C_i A_i)^2}{\beta_{\text{model}}} \xrightarrow[\text{set of BPMs}]{\text{reducing}} 2J_{x,y} = \frac{1}{N_{\text{set}}} \sum_{i=1}^{N_{\text{set}}} \frac{A_i^2}{\beta_{\text{model}}} \quad (2)$$

- $\beta$  can be therefore reconstructed

$$\beta_{\text{amp},i} = \frac{A_i^2}{C_i^2 2J_{x,y}} \quad (3)$$

# Limitations of the existing methods (I): $\beta$ from phase

$\beta$  from phase reconstruction diverges for given values of phase advance between two given BPMs

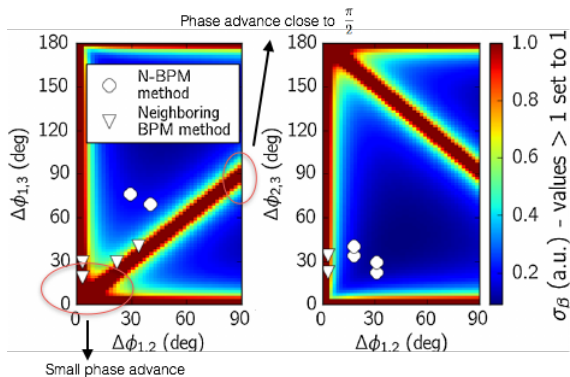

Figure: Langner, A. & Tomas, R.. (2015). "Optics measurement algorithms and error analysis for the proton energy frontier." Physical Review Special Topics – Accelerators and Beams. 18. 031002. 10.1103/PhysRevSTAB.18.031002.

# Limitations of the existing methods (II): $\beta$ from amplitude (LHC)

# Limitations of the existing methods (II): $\beta$ from amplitude (IP 5)

# Disconnecting key quadrupoles from the lattice

- Creating a drift in the area of interest by switching off the quadrupoles surrounding the BPM that wants to be calibrated.

## Disconnecting key quadrupoles from the lattice (II)

- Propagation of the  $\beta$  function in a drift space (no quadrupoles)

$$\beta(s) = \frac{(s - \omega)^2}{\beta^*} + \beta^* \quad (4)$$

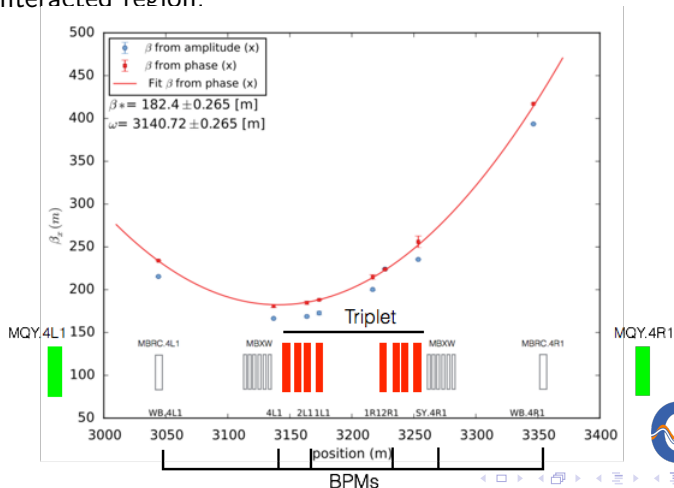

- The  $\beta_{\text{phase}}$  is not affected by strongly localized errors and it can be used as a reference value.
- Calibration factor is the calculated using the equation:

$$C_i^2 = \frac{\beta_{\text{amplitude}}}{\beta_{\text{phase}}} \xrightarrow[\text{to other optics}]{\text{applying}} x_{\text{corrected}} = C_i \cdot x_{\text{measured}} \quad (5)$$

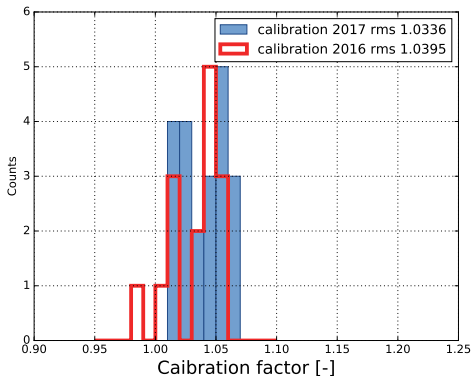

# Disconnecting quadrupoles from the lattice (II): LHC experience

- The experiment in LHC studies are focused on the BPMs placed in the interacted region.

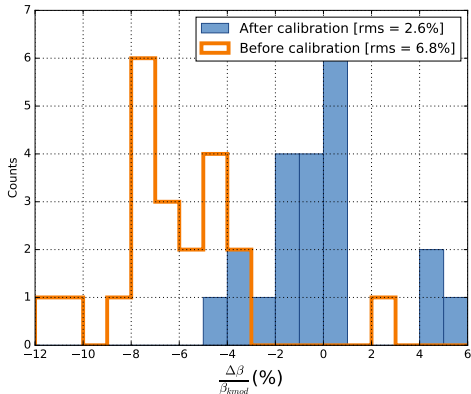

## Disconnecting quadrupoles from the lattice (III)

Summary of the calibration factors measured in 2016 and 2017 in horizontal plane. ( $C_i$ )

Example of application of the calibration factors in 40 cm optics in LHC. (2017)

## Normalized dispersion (I): Introduction

Dispersion function also depends on the calibration factors of the BPMs. Looking for new observables for the dispersion correction, the quantity

$$\frac{D_x}{\sqrt{\beta_{x,\text{amp}}}} \quad (6)$$

appears very interesting since it can be measured independently of the BPM calibration.

Comparison between  $D_x$  and  $ND_x \rightarrow \frac{D_x}{\sqrt{\beta_{x,\text{amp}}}} \sqrt{\beta_{x,\text{phase}}}$ .

$$C_{i,D} = \frac{D_x}{ND_x \cdot \sqrt{\beta_{x,\text{phase}}}} \quad (7)$$

# Normalized dispersion (II): LHC measurements

# Normalized dispersion (III): Dispersion vs Ballistic

- Calibration factor using drift vs using dispersion.

## Moving the working point

- Alternative approach for the scenarios where the phase advance between the neighbor BPM is  $\sim \frac{\pi}{2}$

### Possible solution

- Change the working point in order to have a better resolution of  $\beta$  from phase.

# Conclusions

- Drift method and normalized dispersion method allow to obtain calibration factors of a set of BPMs.
- Calibration factors can be applied into operational optics in order to decrease the  $\beta$ -beating ( $\beta$  from amplitude with respect  $\beta$  from phase).
- Globally, the  $\beta$  from phase resolution can be improved when phase advance is problematic. This can be done by changing the working point of the machine.
