

## JUAS 2016 exam

The following constant will be used in the exercises

elementary electric charge	$e = 1.6 \cdot 10^{-19} \text{ C}$
velocity of light	$c = 2.998 \cdot 10^8 \text{ m/s}$
reduced Planck constant	$\eta = h/2\pi = 1.05 \cdot 10^{-34} \text{ Kg m}^2/\text{s}$
vacuum dielectric constant	$\epsilon_0 = 8.854 \cdot 10^{-12} \text{ F/m}$
electron rest energy	$0.511 \text{ MeV}$
proton rest energy	$938 \text{ MeV}$
classical electron radius	$r_e = 1/(4\pi\epsilon_0) e^2/(mc^2) = 2.81 \cdot 10^{-15} \text{ m}$

$$C_q = \frac{55}{32\sqrt{3}} \frac{\eta}{mc} = 3.84 \cdot 10^{-13} \text{ m}$$

Solve 3 of the following 4 problems.

### Ex. 1:

The formula for the energy loss per turn for an electron with energy  $E$  in a storage ring with dipoles having bending radius  $\rho$  is given, in handy units, by

$$U_0(\text{keV}) = 88.46 \frac{E(\text{GeV})^4}{\rho(\text{m})} \quad (1)$$

- Compute the energy loss per turn by an electron beam with energy 5 GeV travelling in a ring with equal dipoles having bending radius  $\rho = 10\text{m}$ .
- Assuming constant energy loss per turn (1), how many turns it would take for the electrons to radiate all their energy. How does this value compare to the transverse damping time?
- If all the energy losses are due to photons emitted at the critical energy  $\epsilon_c$ , how many photons per turn would be emitted?
- write down the analogous of formula (1) for a proton.

### Ex. 2:

We want to build an electron storage ring with the design energy of 2 GeV, using  $N$  identical bending magnets with identical beam optics in the TME lattice. The target for the horizontal emittance is 2 nm-rad.

- How many bending magnets are required?
- How long are the bending (i.e. the length of the trajectory in the magnet), if the field strength is  $B = 1.4 \text{ T}$ ?
- How do things change for a DBA lattice?

### Ex. 3:

Assume we have a 3 GeV storage ring with a horizontal emittance of  $\epsilon_x = 3 \text{ nm}$ . We want to increase the brightness by building a new lattice reducing the horizontal emittance by a factor 10, to 300 pm. Assume the optics functions at the centre of the undulators are the same in both lattices and they are  $\beta_x = \beta_y = 2\text{m}$  and  $D_x = D_y = D_x' = D_y' = 0$ .

$D_y' = \alpha_x = \alpha_y = 0$ . Assume that the vertical emittance is always 1% of the horizontal emittance.

- a) Compute the photon beam size and divergence for an undulator with  $L = 2$  m emitting in the fundamental wavelength at  $\lambda = 1$  Å and for  $\lambda = 10$  nm;
- b) What is the percentage increase in brightness at  $\lambda = 10$  nm after reducing the emittance as indicated above;
- c) At what wavelengths the increase in brightness becomes negligible;

**Ex. 4:**

A storage ring operates at 3 GeV and has a horizontal emittance  $\epsilon_x = 3$  nm. We want to reduce the emittance to 300 pm by reducing the energy of the ring

- a) What should be the new electron beam energy?
- b) Would this be a good strategy to increase the brightness in a light source? Explain why. [Hint: What happens to the spectrum of the bending radiation? And the undulator radiation? ]
- c) What are the strategies currently proposed to achieve ultra low emittance lattices? Explain why.
