NM data vs. GCR modulation

Oulu Neutron Monitor

1964/04/01 00:00 - 2016/01/01 00:00 UT. Resolution: 1 month(s). Average CR: 6145.49

1965 1967 1969 1971 1973 1975 1977 1979 1981 1983 1985 1987 1989 1991 1993 1995 1997 1999 2001 2003 2005 2007 2009 2011 2013 2015

Force-field approximation

Under some (over)simplifying assumptions,

$$\frac{\partial f}{\partial r} + \frac{VP}{3\kappa} \cdot \frac{\partial f}{\partial P} = 0$$

$$j = P^2 f \rightarrow j/P^2(T, 1AU) = j/P^2(T + \Phi, LIS)$$

Analytical solution in the form of characteristic curves can be obtained

$$j_{1AU}(T) = j_{LIM}(T + \Phi) \frac{T(T + 2T_0)}{(T + \Phi)(T + \Phi + 2T_0)}$$

$$\Phi = \frac{V(R-1)}{3\kappa_0}$$

is the modulation strength (in MV)

variable parameter

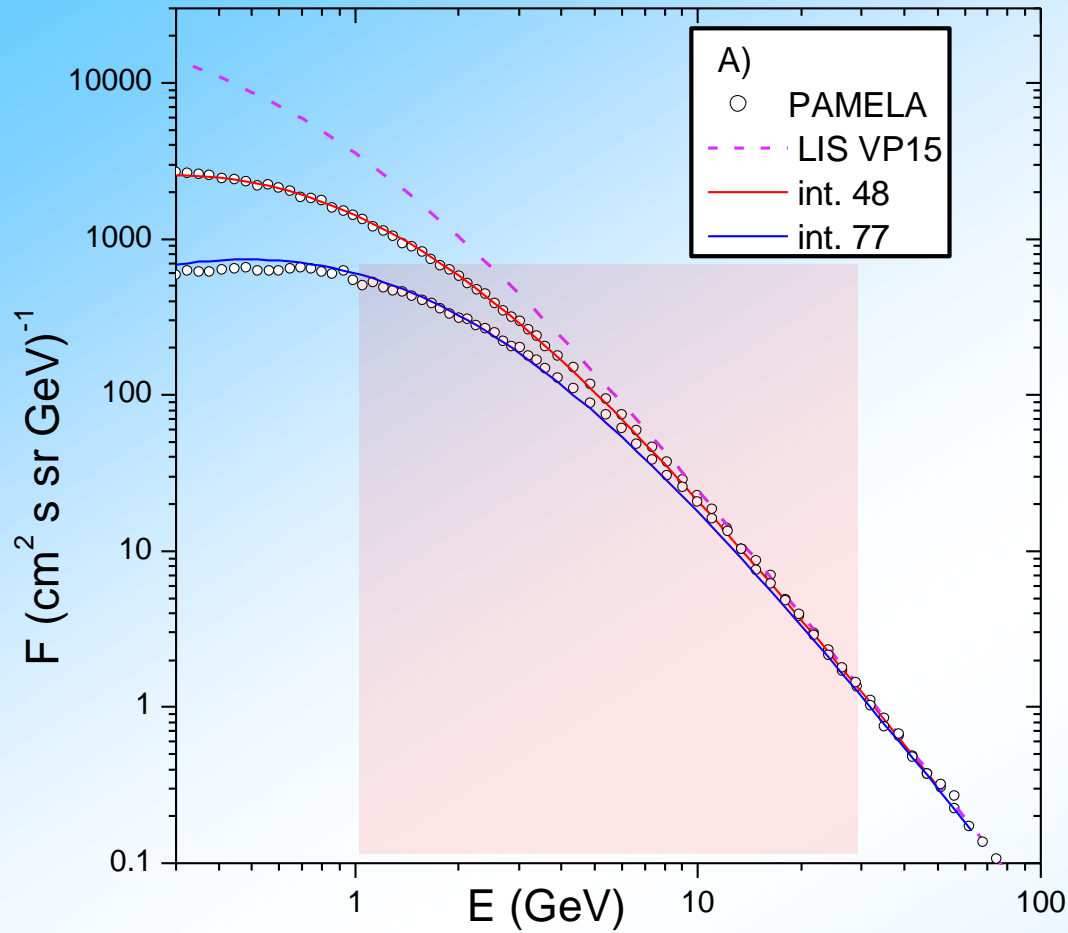

and

Vos & Potgieter, 2015

$$J_{LIS} = 2.7 \cdot 10^3 \frac{T^{1.12}}{\beta^2} \left(\frac{T + 0.67}{1.67} \right)^{-3.93}$$

Fit of the data

$$\chi^2 = \sum_j \left(\frac{J_{\text{mod}}(T_j) - J_{\text{meas}}(T_j)}{\sigma_j} \right)^2$$

Fit by χ^2 in the range 1–30 GeV (n=42), which is the effective range of NM response.

Distribution of χ^2_{min}

$\sim 0.3/\text{DoF} \rightarrow$ too conservative errors?

New PAMELA data: 2006 - 2014

NM yield functions

$$N(T, h) = \frac{1}{\kappa} \sum_i \int_{T_{c,i}}^{\infty} J_i(T, t) \cdot Y_i(T, h) \cdot dT,$$

$$J_{\text{LIS},\alpha} = 0.3 J_{\text{LIS},p}$$

PAMELA 2006-2009: Good agreement?

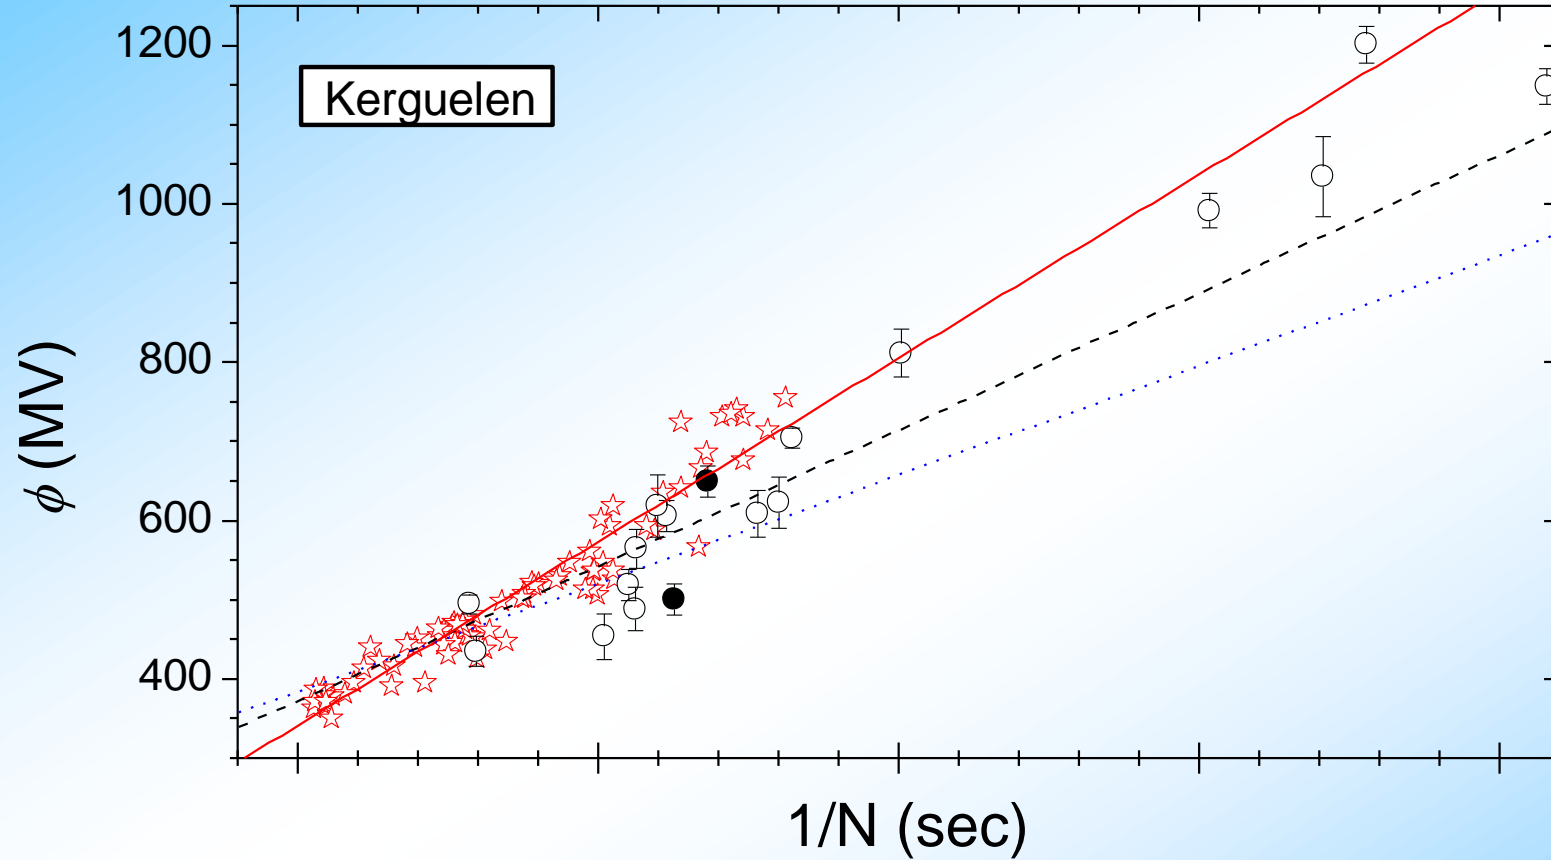

Comparison with NM

PAMELA vs. Oulu NM

PAMELA vs. Kerguelen NM

PAMELA vs. Inuvik NM

Discrepancy

- There is a **discrepancy** (small, <100 MV, but systematic) between the energy spectra of GCR protons measured in space and those reconstructed from ground-based NM data.
- Both used yield-function models disagree with the data, but the results based on Mi13 lie closer to the experimental data than those based on Ma16.

REASON?

- 1) Possible degradation of the PAMELA sensitivity with time, thus overestimated modulation potential during the late years: BUT the spectral shape is not distorted, and the discrepancy is consistent with independent balloon-borne data → **unlikely**
- 2) Incorrect yield function of NM: overestimate of the low-energy part or underestimate of the high-energy tail
- 3) Alphas do not behave as we expect.

We cannot distinguish now → more data needed (AMS?)

Summary

- GCR **proton spectra** measured by PAMELA **are well parameterized by the force-field model** in the range 350–750 MV for the LIS by Vos & Potgeiter (2015).
- The obtained ϕ -values are **in agreement with** those calculated from **NM data** (Usoskin et al., 2017) for **low solar activity** 2006–2012, but **diverge during the maximum** of solar cycle 24 around 2013–2014.
- The empirical relation between the modulation potential and the (inverted) NM count rate is steeper than the modelled one. The discrepancy is small ($< \sim 10\%$) but systematic. Results based on the **NM yield function by Mishev et al. (2013)** **lie closer** to the data points than those based on the results by Mangeard et al. (2016).
- **The reason for the discrepancy is unclear.** We speculate that a likely reason is a possible underestimate of the NM yield function in the high energy range. More investigation is needed with the use of an independent dataset \rightarrow GCR spectra measured by the AMS experiment.

THANK YOU !
