Detector response to long term irradiation and high rate capability are key elements for new muons detectors especially in view of High-Luminosity LHC

- GIF++ at CERN combines a high intensity photon source (14 TBq Cesium source) with a muon beam
- The source produces 662 keV photons (50% of the flux, the other 50% are about equally distributed between ≈100 keV and 662 keV)
- The particle flux can be modified, with absorbers filters shielding the source

A current of about $5 \times 10^7$ photons/cm$^2$ is expected at the reference position closest to the source

D:Pfeiffer et al., "The radiation field in the Gamma Irradiation Facility GIF++ at CERN", arXiv:1611.00299v1
Two *bulk* resistive Micromegas prototypes (T5, T8) have been installed in GIF++ in 2015:
- Active area of 10x10 cm$^2$
- 5 mm drift, $\sim$100 $\mu$m amplification gaps
- The copper readout strips (pitch 0.4 mm) are covered by a 50 $\mu$m thick Kapton foil carrying resistive strips (0.5-1 M$\Omega$/cm$^2$)
- Mesh consisting of 18 $\mu$m wires, with opening of 45 $\mu$m

The aim was to accumulate at least 0.2 C/cm$^2$ (equivalent to $\sim$10 years for inner muon detectors at HL-LHC) to evaluate the impact of long term irradiation on the detector

The setup has been mounted as close as possible to the source to maximise the photon rate
- Estimation of the particle rate has been performed by counting single photon conversions in the gas
- Geant4 simulation of the expected particle rate seen by the detectors has been performed
- A sensitivity of \(\sim 1.7 \times 10^{-3}\) has been measured, in good agreement with the simulation accounting for the GIF++ source and detector structure

The detector performance has been studied in a high rate photon background in combination with a muon beam:

- The Hough transform has been used to identify muons in the photon background.
- The resolution and the most-probable-value of the muon cluster charge have been studied.
- No sign of performance degradation is observed up to 70 kHz/cm².
Long term irradiation

Accumulated charge has been estimated monitoring the current on the detectors

More than 0.3 C/cm² have been collected since May 2015
Performance tests have been performed in May 2017 (after 0.2 C/cm²) and January 2018 (after 0.3 C/cm²)

T8 = 333.25 mC/cm²
T5 = 317.78 mC/cm²
The efficiency of the detectors has been measured by means of cosmic muons in the lab and in test-beams.

The efficiency is defined by the presence of a cluster of strips with a signal around the expected muon position as obtained from the tracking chambers.

Results show:
- No reduction of the detector efficiency
- No reduction of the working point
Detector gain before, during and after irradiation

Gain measurements carried with $^{55}$Fe sources in 2015, 2017, 2018:
- HV supplied to drift electrode and mesh
- Current read from readout strips
- Trigger rate obtained from mesh signals (~300k/cm$^2$)

Results show:
- No reduction of the gain throughout the irradiation period
The current has been monitored:
• Detector position has been changed several times because of test-beams, tests in the lab, facility needs
• Irradiation time intervals where conditions are unchanged (same position/distance) are considered
• Current of about 2 μA with source fully open and at detector working point

Results show:
• Current is stable during the whole period
Conclusions

Two bulk resistive strips Micromegas prototypes have been exposed to intense photon source since 2015 at GIF++ facility at CERN:

- A sensitivity of $1.7 \times 10^{-3}$ to the GIF++ photon spectrum has been obtained by comparing the converted photons with the simulated flux reaching the detectors
- Spatial resolution and cluster charge distributions have been measured under different background rates ranging from 0 to 70 kHz/cm$^2$
- 0.3 C/cm$^2$ has been collected in total
- Detector efficiency to muons and gain have been measured three times, once before irradiation, once after accumulation 0.2 C/cm$^2$ and finally after 0.3 C/cm$^2$: no detectable degradation of the performance has been observed
- Current behaviour over time does not show variations throughout the whole irradiation period
- Similar study on Micromegas prototype has been performed* with similar outcome
