

Measurement of θ_{13} in the reactor neutrino events with neutron captures on Hydrogen at RENO

Friday, July 6, 2018 8:15 PM (15 minutes)

RENO has been taking data since August, 2011 and successfully measured the smallest neutrino mixing angle, θ_{13} . The measurement values are obtained from the observed reactor antineutrino events with neutron captures on gadolinium (n-Gd) in the target detector region. In addition, RENO has successfully measured the mixing angle as well, using an independent sample with neutron captures on hydrogen (n-H). Because of a large accidental background in the n-H sample, the analysis requires additional reduction of backgrounds. This independent measurement provides a valuable systematic cross-check of the θ_{13} measurement using the n-Gd sample. In this talk, we will present the results from the 1500 days of n-H data sample.
