GENERAL

JUNO (Jiangmen Underground Neutrino Observatory) is a 20 kton multipurpose neutrino detector under construction in China and it will be completed in 2021. JUNO will be located in an underground laboratory, ~700 m under sea level, 53 km away from 2 nuclear power plants, total power ~36.6 GW, which will provide the flux of $\nu_e$.

Two main channels to identify neutrino events, Inverse Beta Decay and elastic scattering:

- $\bar{\nu}_e + p \rightarrow e^+ + n$ (Inverse Beta Decay)
- $\nu_e + e^- \rightarrow \nu_e + e^-$ (Scattering on electron)

Target energy resolution:

$$\frac{3\%}{\sqrt{E[MeV]}}$$

MASS HIERARCHY

Main physics goal is the determination of the neutrino Mass Hierarchy. To see it JUNO can use two different methods:

- Atmospheric mass squared difference manifest itself cyclically in the energy spectrum so comparing the experimental spectrum with the theoretical one JUNO will extract the information about the hierarchy after performing a $\chi^2$ test.
- The oscillation interference effect is more visible in the frequency domain after a Fourier transformation of the spectrum. There are two possibilities:
  - Fourier sine transform (FST)
    $$FST(\omega) = \int_{t_{min}}^{t_{max}} f(t) \sin(\omega t) \, dt$$
  - Fourier cosine transform (FCT)
    $$FCT(\omega) = \int_{t_{min}}^{t_{max}} f(t) \cos(\omega t) \, dt$$

SUPERNova NEUTRINO

Another important topic for JUNO is the study of neutrinos coming from astrophysical sources, in particular Supernova neutrino burst and SN neutrino diffusive flux. JUNO can see SN’s $\nu$ through different channels:

- inverse beta decay, is the golden channel with $\sim5000^\circledast$;
- $\nu$-e elastic scattering, it can provide information about $\nu_e \sim 1000^\circledast$;
- $\nu$-e elastic scattering, it can provide information about $\nu_e \sim 300^\circledast$.

\*Events are for a core collapse SN at $\sim10$ kpc

JUNO is also sensitive to:

- Geoneutrino with 300 events/year$^{\circledast}$;
- Solar neutrino, low threshold and high energy sensitivity make studies on the solar metallicity possible with high statistic;
- Atmospheric neutrino, test on Lorentz invariance, search for sterile neutrinos and DM annihilation, search for nucleon decay.

GEONEUTRINO

Measuring the $\nu_e$ emitted in the $^{238}$U and $^{232}$Th radioactive decay chains (called geoneutrinos), helps in testing the Th/KU rate. This is important to understand the abundance of radioactive elements (to know exactly the composition of Earth) and the radiogenic heat contribution.

DARK MATTER

Resonant interactions between neutrinos from a Galactic supernova and dark matter particles can lead to a sharp dip in the neutrino energy spectrum. Due to its excellent energy resolution, measurement of this effect can provide evidence for such couplings.

SOLAR NEUTRINO

The JUNO detector has many advantages in performing solar neutrinos measurements. It has the benefit of high light yield, very high energy resolution and low energy threshold. Thanks to this features JUNO will remeasure the flux of $^7$Be and $^8$B
