# Searches for Dark Matter mediators with the ATLAS detector

Sabine Crépé-Renaudin

Laboratoire de Physique Subatomique et de Cosmologie, Grenoble France

on behalf the ATLAS collaboration

# Dark matter: observations

## Evidence of dark matter

- From astrophysics and cosmology observations at **different scales, all consistent**

Galaxy rotation

Galaxy clusters via Xrays and gravitational lensing, collisions

Nucleosynthesis

(Schramm & Turner 1998).

Cosmic microwave background

© ESA, Planck Collaboration

Large scale structure formation

© simulations were performed at the [National Center for Supercomputer Applications](#) by [Andrey Kravtsov](#) (The University of Chicago) and [Anatoly Klypin](#) (New Mexico State University).  
Visualizations by [Andrey Kravtsov](#).

# Dark matter: how to detect it ?

## Indirect detection

- Search for charged cosmic rays, gamma rays or neutrinos

© NASA / Sonoma State University, Aurore Simonnet

## Direct detection

- Use scattering of DM on a nucleus

## Collider search

- Produce DM particles from SM particles collisions

→ hyp: the dark matter is made up Weakly Interacting Massive Particles (WIMPS)

# Dark matter search at LHC

## Search for particles from (UV) complete theories

- simulate particles decays, dark matter reconstructed as missing transverse energy
  - Supersymmetry, Extra dimensions , Little Higgs, ...

## Use of effective field theory (EFT)

- many theories show common low energy behaviour, EFT allows more general searches

→ If  $M \gg q$

- describes new interactions with few operators
- focus of LHC run 1 analyses

### → Advantages:

- model independent
- Allows to translate LHC results into direct search frames (with some care on the hypothesis)

### → Limitations:

- EFT valid only if  $M \gg q \Rightarrow$  Run 1 limits  $M \sim 1 \text{ TeV} \Rightarrow$  should not use  $E > 1 \text{ TeV}$
- Loose correlations that can be used in a complete theory

# Dark matter search at LHC: simplified models

## Simplified models

- In between EFT and complete theory: add a single DM candidate (Dirac fermion) and a mediator
- Allow to relax the  $q^2$  limit but more model dependent
- Allow to use other signatures to probe mediator and thus constrain the model

## Common model and scenarios

- ATLAS/CMS + theory Dark Matter forum defined the DMSimp model ([arXiv:1507.00966](https://arxiv.org/abs/1507.00966))
- Recommendations for benchmark scenarios ([arXiv:1703.05703](https://arxiv.org/abs/1703.05703))
- Madgraph implementation (LO/NLO)

# Dark matter search at LHC: simplified models

## Simplified models

- In between EFT and complete theory: add a single DM candidate (Dirac fermion) and a mediator
- Allow to relax the  $q^2$  limit but more model dependent
- Allow to use other signatures to probe mediator and thus constrains the model

- MET + X signatures were the focus of Michaela Queitsch-Maitland's talk

- di-fermion signatures are the focus of this talk

- Mediator could have spin 0 or 1, charged or neutral
  - ▶ recent results about spin 1, neutral mediator will be shown here

# Simplified model: neutral (axial-)vector mediator

## Model:

- Free parameters:  $m(\chi)$ ,  $m(\text{med})$ ,  $g_{\text{DM}}$  and  $g_q, g_l$
- Minimal width computed according to couplings and considered particles mass
  - mediator decays considered = ones strictly necessary to maintain model self-consistency

$$\mathcal{L}_{\text{vector}} = g_q \sum_{q=u,d,s,c,b,t} Z'_\mu \bar{q} \gamma^\mu q + g_\chi Z'_\mu \bar{\chi} \gamma^\mu \chi$$

$$\mathcal{L}_{\text{axial-vector}} = g_q \sum_{q=u,d,s,c,b,t} Z'_\mu \bar{q} \gamma^\mu \gamma^5 q + g_\chi Z'_\mu \bar{\chi} \gamma^\mu \gamma^5 \chi$$

## Scenarios:

- Chosen to show the complementarity of the DM production analyses (mono X) and the mediator-to-visible analyses (di X)

Scenarios	$g_q$	$g_{\text{DM}}$	$g_l$
V1: vector model with only couplings to quarks	0.25	1.0	0.
V2: vector model with small couplings to leptons	0.1	1.0	0.01
A1: axial-vector model with only couplings to quarks	0.25	1.0	0.
A2: axial-vector model with equal coupling to quarks & leptons	0.1	1.0	0.1

# Di-jet: high mass

## Analysis

- 2 small R-jets  $j$  selected with  $p_T > 440$  GeV and  $60$  GeV
  - $|y^*| < 0.6$  to reduce background from QCD process  $\rightarrow m(jj) > 1.1$  TeV
- Background obtained fitting the  $m(jj)$  distribution
- BumpHunter [Arxiv: 804.03496] algorithm used to quantify statistical significance of any local excess/deficit
- No deviation from SM observed, limit set on cross-section and coupling to quarks

$\sqrt{s} = 13$  TeV,  $L = 36.1$  fb $^{-1}$

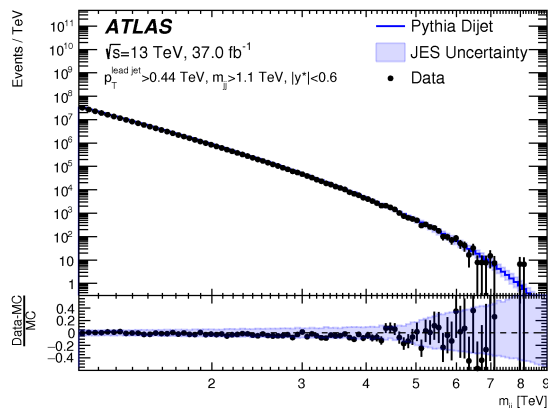

♦ [EXOT-2016-21](#)

♦ [Phys. Rev. D 96 \(2017\) 052004](#)

$y^*$  is the jet rapidity difference:

$$y = \frac{1}{2} \ln \left[ \frac{(E + p_z)}{(E - p_z)} \right]$$

$$|y^*| = 0.5 \cdot |y_1 - y_2|$$

# Di-jet: how to get sensitive to lower masses

Di-jet analysis uses single jet trigger: lowest unprescaled ATLAS trigger has  $p_T$  threshold at 380 GeV

→ restrain sensitivity of analysis on  $m_{jj}$  above 1.1 TeV

To recover sensitivity at lower mass, 2 strategies:

- Trigger level analysis (TLA)

40 MHz

Level 1 trigger

100 kHz

High Level trigger  
HLT

Main stream = 1 kHz, ~1Mb/evt

Trigger Level ana = 2-3 kHz, < 5 kb/evt

- Trigger on an other object: use di-jet + ISR topology

- ISR = jet or photon, boost the di-jet resonance

→ gives access to lower mass range at the price of lower cross-section

# Di-jet: trigger level analysis

$\sqrt{s} = 13 \text{ TeV}$ ,  $L = 29.3 \text{ fb}^{-1}$   
 ♦ [EXOT-2016-20](#)  
 ♦ [arXiv:1804.03496](#)

## → Analysis done at HLT trigger level

- 2 (calibrated) jets selected with  $p_T > 185 \text{ GeV}$  and 85 GeV (minimal info stored: 0.5% of an event)
- 2 rapidity regions defined:
  - $|y^*| < 0.6$  for  $700 \text{ GeV} < m_{jj} < 1800 \text{ GeV}$  for L1 trigger with  $E_T > 100 \text{ GeV}$  threshold
  - $|y^*| < 0.3$  for  $m_{jj} > 450 \text{ GeV}$  for L1 trigger with  $E_T > 75 \text{ GeV}$  threshold
- sliding window fit, no deviation wrt SM observed, limits set

# Di-jet (large R-jet) + ISR

$\sqrt{s} = 13$  TeV,  $L = 29.3$  fb $^{-1}$

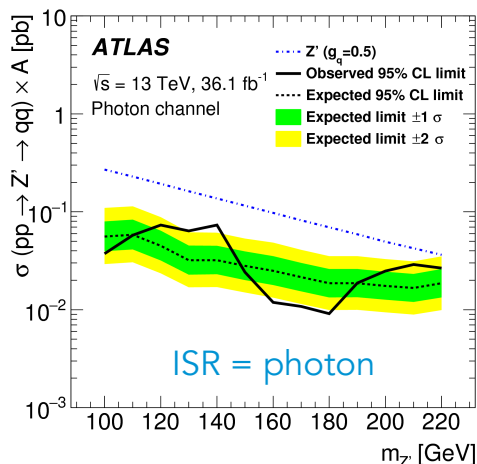

- ♦ EXOT-2017-01
- ♦ arXiv:1801.08769

## Di-jet + ISR

- Previous analysis done at  $\sqrt{s} = 13$  TeV with  $L = 15.5$  fb $^{-1}$  [ATLAS-CONF-2016-070](#)

## Boosted di-jet +ISR

- use high  $p_T$  ISR to lower trigger threshold for the event, ISR = jet or photon
  - at the price however of smaller cross-section
- use boosted topology: select a single large-radius jet (consistent with di-jet substructure) recoiling against a hard jet or photon from ISR
- ISR jet (photon): large R-jet  $p_T > 450$  (200) GeV, ISR  $p_T > 450$  (155) GeV

# Di-bjet

## Analysis

- Low and high mass regions probed
  - high mass:  $m(jj) > 1.2$  TeV,  $p_T(j) > 430$  GeV, 80 GeV, using usual jet trigger
  - low mass:  $570 \text{ GeV} < m(jj) < 1.5$  TeV, using di-jet trigger ( $p_T$  threshold 150 and 50 GeV with online b-tagging;  $p_T(j) > 200$  GeV)
- To reduce background and enhance s-channel process, cut on rapidity difference  $y^* = (y_1 - y_2)/2$  between jets:  $|y^*| < 0.8$  (0.6) for high (low) mass

$\sqrt{s} = 13 \text{ TeV}$ ,  $L = 36.1\text{-}24.3 \text{ fb}^{-1}$   
 ♦ EXOT-2016-33  
 ♦ arXiv:1805.09299

# Di-jet analysis complementarity

$\sqrt{s} = 8-13 \text{ TeV}$ ,  $L = 3.6-37 \text{ fb}^{-1}$   
 \* [ATLAS EXOTIC SUMMARY PLOTS](#)

→ Limits on the DM mediator coupling to quarks

# Top quark pair

## Analysis

- lepton+jets final state, resolved and boosted regimes

low top  $p_T$

high top  $p_T$

→ will be interesting to look at (pseudo-)scalar mediators

► Interference !

► done at 8 TeV:

- EXOT-2016-04/
- Phys. Rev. Lett. 119 (2017) 191803

# Di-lepton analysis

$\sqrt{s} = 13 \text{ TeV}$ ,  $L = 36 \text{ fb}^{-1}$

♦ [EXOT-2016-05](#)

♦ [JHEP 10 \(2017\) 182](#)

## Analysis

- Select 2 same flavour leptons (opposite sign for muon channel)
  - $E_T(e) > 30 \text{ GeV}$ ,  $p_T(\mu) > 30 \text{ GeV}$
- Clean final state and much lower trigger threshold than for di-jet analyses

Combined ee and  $\mu\mu$  limit

# Complementarity with mono X + MET analyses

$\sqrt{s} = 8-13$  TeV,  $L = 3.6-37$  fb $^{-1}$   
 • [ATLAS EXOTIC SUMMARY PLOTS](#)

→ Exclusions from mono-jet, mono-photon and di-jets for axial-vector coupling

- Note: coupling dependence is important !
- Resonance search independent of mediator mass for  $m_{\text{med}} < 2 \cdot m_{\text{DM}}$

A1:  $g_{\text{DM}}=1$ ,  $g_q=0.25$ ,  $g_l=0$

A2:  $g_{\text{DM}}=1$ ,  $g_q=0.1$ ,  $g_l=0.1$

# Complementarity with mono X +MET analyses

$\sqrt{s} = 8-13 \text{ TeV}$ ,  $L = 3.6-37 \text{ fb}^{-1}$   
 • ATLAS EXOTIC SUMMARY PLOTS

→ Exclusions from mono-jet, mono-photon and di-jets for vector coupling

- Note: couplings dependence is important !

V1:  $g_{DM}=1$ ,  $g_q=0.25$ ,  $g_l=0$

V2:  $g_{DM}=1$ ,  $g_q=0.1$ ,  $g_l=0.01$

# Complementarity with direct detection

$\sqrt{s} = 8-13 \text{ TeV}$ ,  $L = 3.6-37 \text{ fb}^{-1}$   
 \* ATLAS EXOTIC SUMMARY PLOTS

Beware!  
 validity only for this  
 choice of model...

Note: limits at  
 95% CL for ATLAS,  
 90% CL for direct  
 detection...

## Axial-Vector mediator / Spin dependent

## Vector mediator / Spin independent

# Summary and perspectives

## Extensive program of dark matter search with the ATLAS experiment

- In the context of simplified model, analyses looking for DM mediator decaying into SM particles are powerful and show nice complementarity with DM MET signatures
- No sign of dark matter though, in the  $36 \text{ fb}^{-1}$  run 2 data scrutinised ... but much more to come (x4 data on tape)!
- These results are also complementary to dark matter direct searches

## Much more to explore...

- Spin 1 charged mediator, FCNC, spin 0 mediator in simplified model with 1 mediator and 1 DM particle
- Extension of 2 HDM with a pseudo-scalar: very rich phenomenology

TO GO FURTHER...

# Dark matter: what do we know about ?

## Properties

- It makes up 85% of the matter in the Universe
  - It is massive
- It interacts weakly with ordinary matter (at least through gravitation)
  - It is neutral
- It interacts weakly with itself
- It is stable (a minima very long-lived, order of the age of the universe)
  - ➡ Ruled out SM Z and Higgs
  - Need a symmetry to prevent it to decay ex T-parity
- It is “cold” ie non relativistic
  - ➡ ruled out SM neutrinos (also not enough massive)

© Cold, Warm, and Hot dark matter simulations, credit ITP, University of Zurich.

# Dark matter: which candidates ? Associated theories ?

## Candidates

- WIMPs = Weakly Interacting Massive Particles
  - WIMP “miracle” : weak cross-section + particle mass  $\sim 1$  TeV  $\sim$  relic density
- Susy neutralinos
- Kaluza-Klein photon
- Very Weak Interacting Massive Particles
  - gravitinos
  - Axions: to solve the strong CP problem, unstable but long lived
  - Sterile neutrinos: to explain neutrino masses
  - Kaluza Klein gravitons
  - ...
- Could be also a more complex sector with several particles and interactions

© Tim Tait

## Theories

- Supersymmetry
  - Symmetry: R-parity
- Extra dimensions
  - Symmetry : KK parity
- Little Higgs
  - Symmetry: T-parity
- QCD axions
- ...

# Comparison with direct detection

DM-proton

DM-neutron

Axial-Vector mediator  
 $g_q=0.1, g_l=0.1, g_{DM}=1$

Axial-Vector mediator  
 $g_q=0.25, g_l=0, g_{DM}=1$

# Jet Energy Scale

$\sqrt{s} = 13 \text{ TeV}$ ,  $L = 36 \text{ fb}^{-1}$   
 ♦ [PERF-2016-04](#)  
 ♦ [Phys. Rev. D 96 \(2017\) 072002](#)

- ▶ Jet energy scale uncertainty is 1% for central jets with  $p_T$  of 500 GeV and grows to 3% for jets with  $p_T$  of 2 TeV
- ▶ Di-jet mass resolution is 2.4% and 2.0% for dijet masses of 2 TeV and 5 TeV, respectively

# Dijet analyses

## Di-jet invariant mass fit

- ▶ Used for previous analyses:

$$f(z) = p_1(1 - z)^{p_2} z^{p_3} z^{p_4 \log z}$$

- where  $z = m_{jj}/\sqrt{s}$  and the  $p_i$  are parameters

- ▶ New: sliding-window fitting technique fitting only restricted regions of the spectrum

- windows  $\sim 1/2$  total number of bins  $\Rightarrow$  whole signal contained

$\Rightarrow$  more flexibility, 3 parameters sufficient

$\Rightarrow$  new method validated

## TLA di-jet analysis

- Sliding window fit

- $f(x) = p_1(1 - x)^{p_2} x^{p_3+p_4 \ln x + p_5 \ln x^2}$  or  $f(x) = p_1 x^{-p_2} e^{-p_3 x - p_4 x^2}$
