

Black hole (and other) dark matter

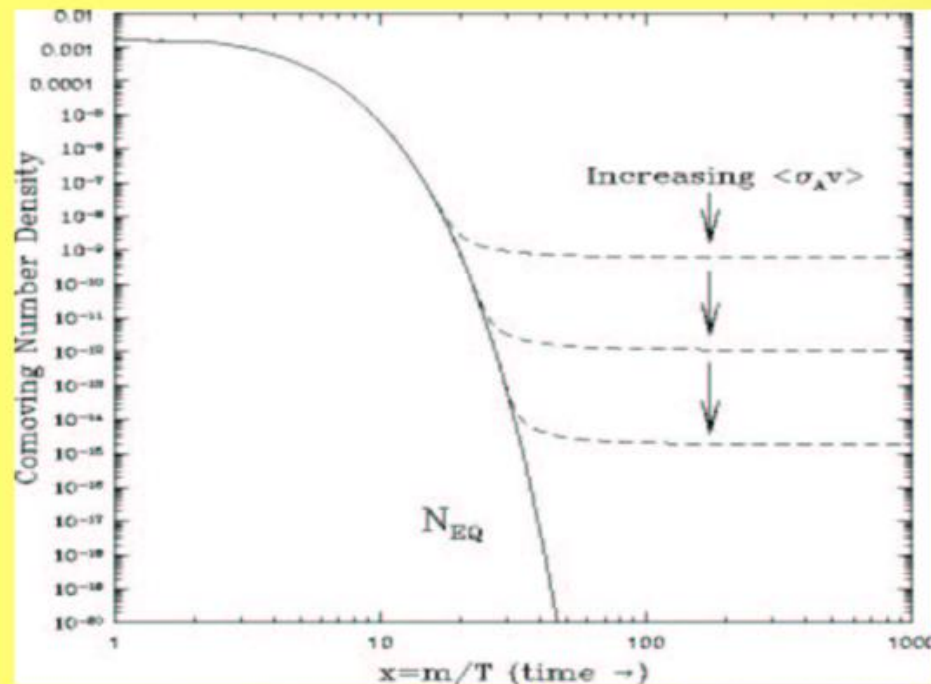

IDM 2018

Dark matter!!

What is it?

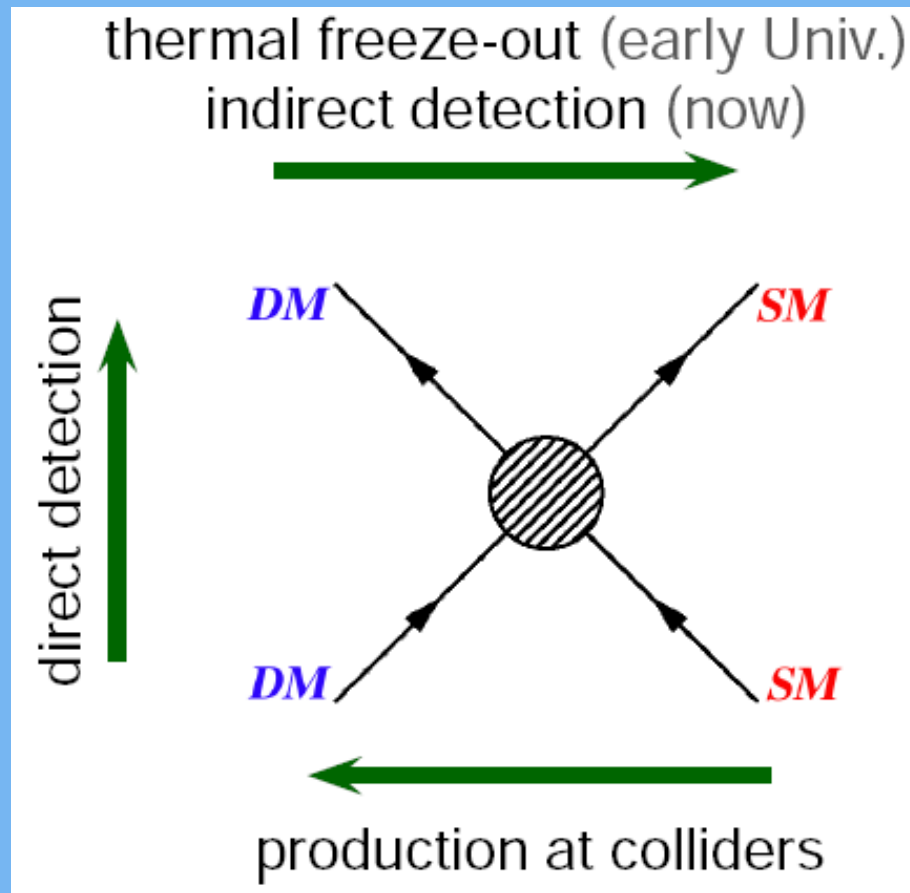

The Party line (~1985—2015)

- Weakly Interacting Massive Particles (WIMPS).
e.g., neutralinos

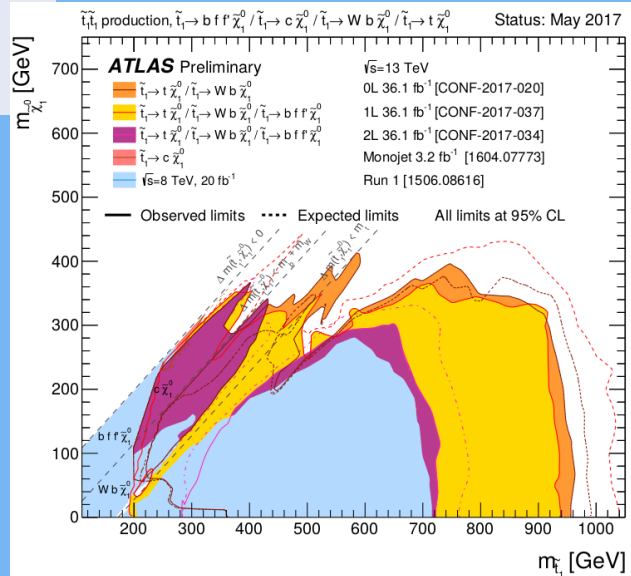

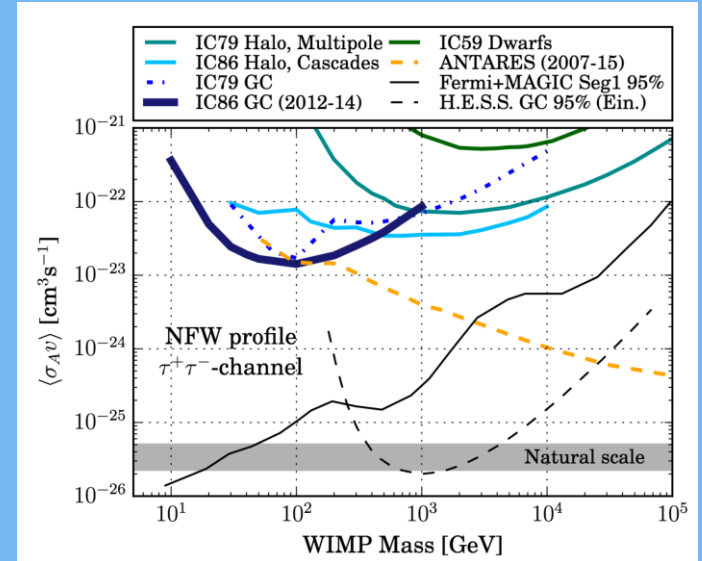

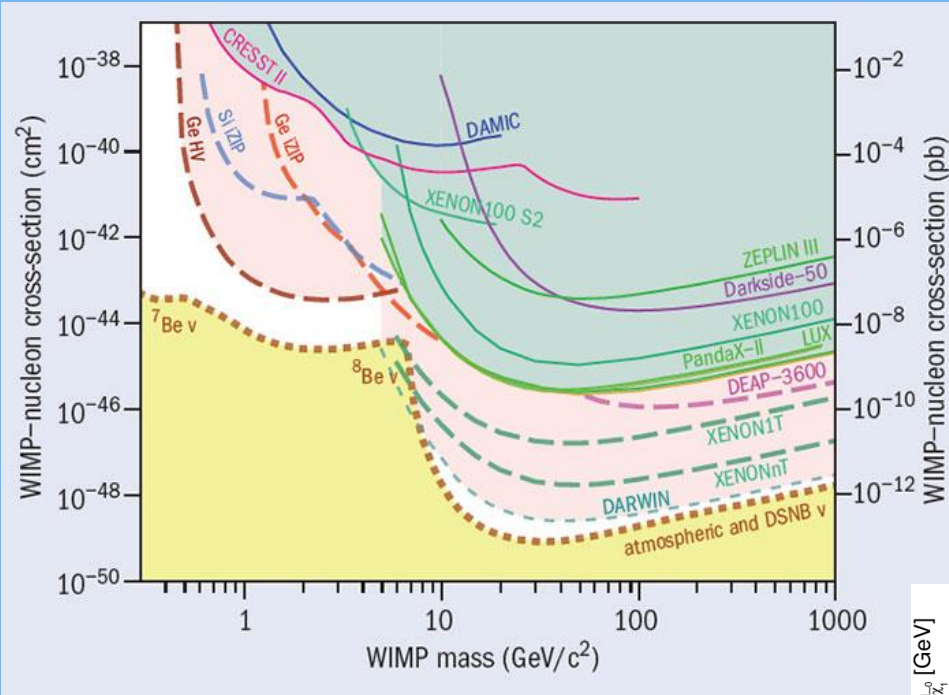

$$\Omega_{\chi} h^2 \approx \frac{3 \times 10^{-27} \text{ cm}^3 / \text{sec}}{\langle \sigma v \rangle}$$

Binary black hole

$$m_1 = 36^{+5}_{-4} M_{\odot} \quad m_2 = 29^{+4}_{-4} M_{\odot}$$

Where do these black holes come from?

Probably stellar remnants (binaries?
globular clusters?)

Still....

- The two black holes in first system each had masses roughly 30 times that of the Sun!!

Did LIGO detect dark matter?

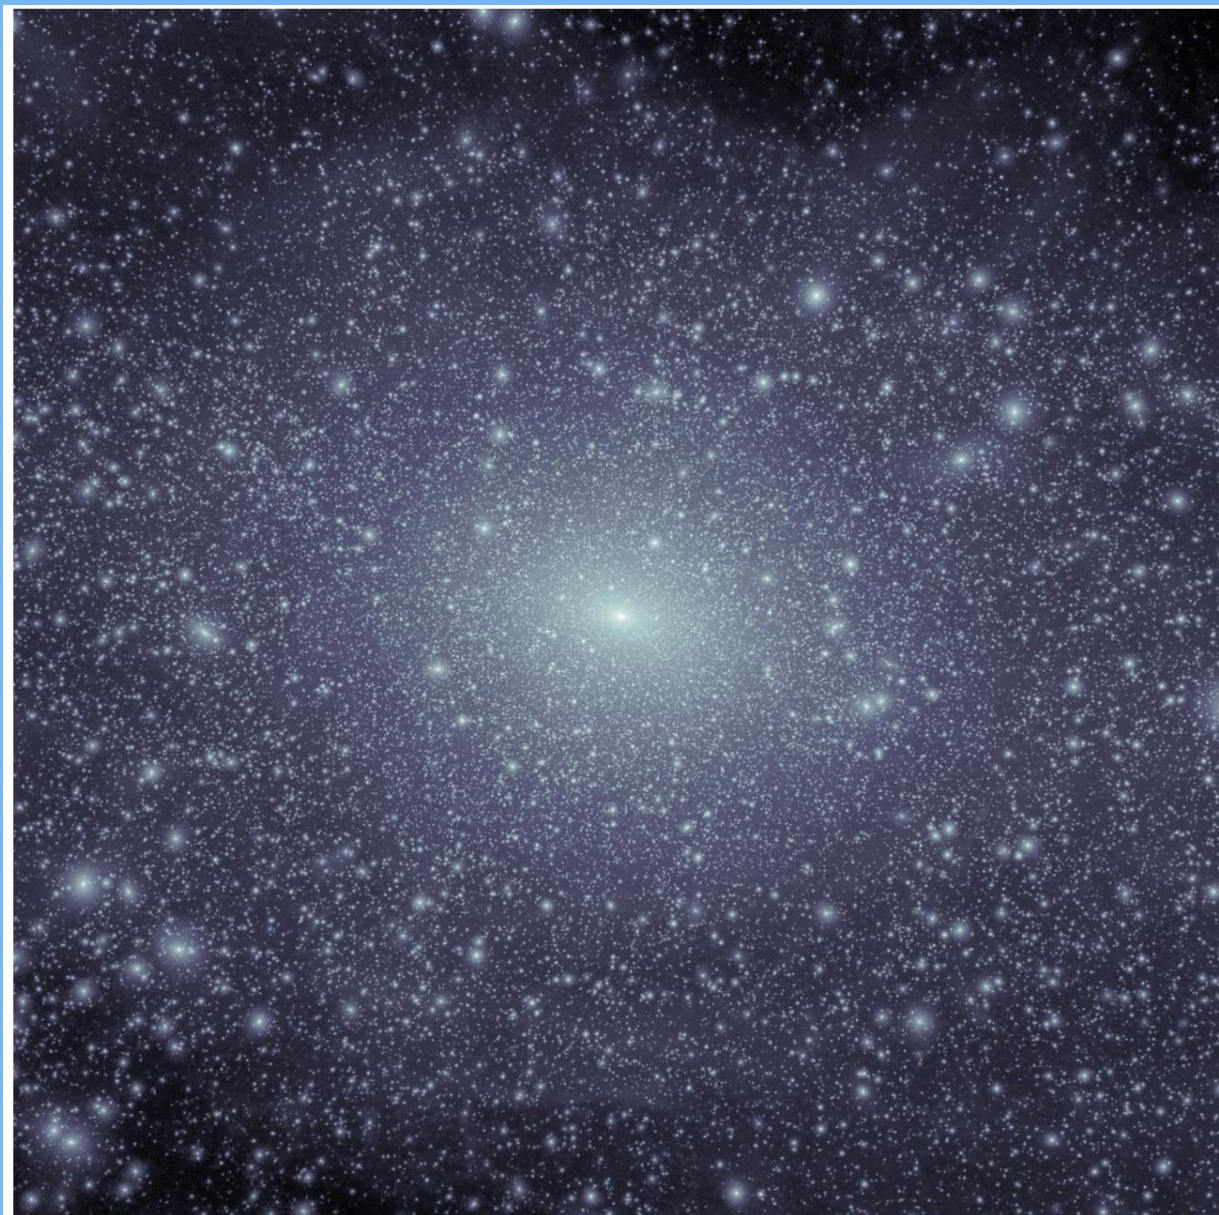

(Bird, Cholis, Munoz, Ali-Haimoud, Kamionkowski, Kovetz, Raccanelli, Riess, 2016)

- highly speculative; not crazy
- Surprising coincidence: If black holes of 30 solar masses make up the dark matter, they merge with rate comparable to that inferred from the initial LIGO event! (Bird et al. 2016)

Suppose DM = 30-Msun BHs

Gravitational radiative recombination

$$\begin{aligned}\sigma &= 2^{3/7} \pi \left(\frac{85 \pi}{6 \sqrt{2}} \right)^{2/7} R_s^2 \left(\frac{v_{\text{pbh}}}{c} \right)^{-18/7} \\ &= 1.37 \times 10^{-14} M_{30}^2 v_{\text{pbh}-200}^{-18/7} \text{ pc}^2,\end{aligned}$$

$$\mathcal{V} = 5 f(M_c/500 M_\odot)^{-11/21} \text{ Gpc}^{-3} \text{ yr}^{-1}$$

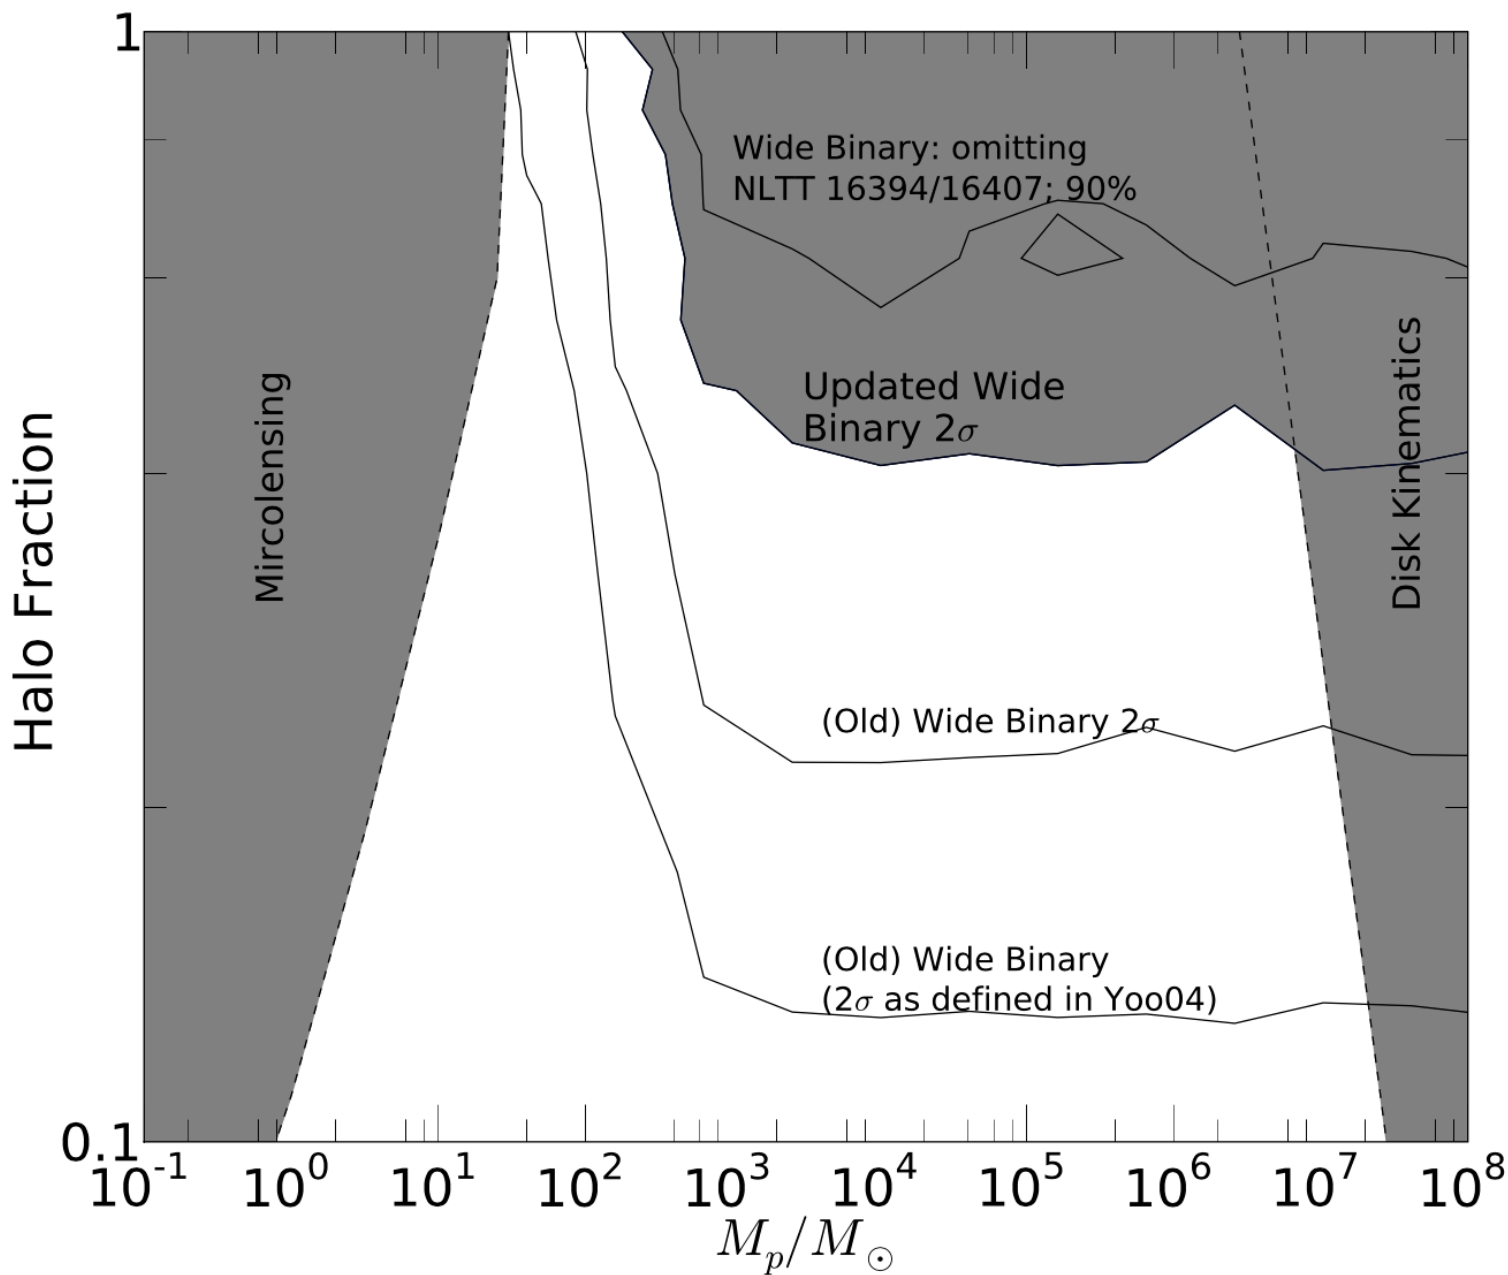

$$\mathcal{V} = 5 f(M_c/500 M_\odot)^{-11/21} \text{ Gpc}^{-3} \text{ yr}^{-1}$$

assuming that the BBH merger rate is constant in the comoving frame, we infer a 90% credible range of $2\text{--}53 \text{ Gpc}^{-3} \text{ yr}^{-1}$ (comoving frame). Incorporating all triggers that pass the search threshold while

$$\mathcal{V} = 5 f(M_c/500 M_\odot)^{-11/21} \text{ Gpc}^{-3} \text{ yr}^{-1}$$

assuming that the BBH merger rate is constant in the comoving frame, we infer a 90% credible range of $2\text{--}53 \text{ Gpc}^{-3} \text{ yr}^{-1}$ (comoving frame). Incorporating all triggers that pass the search threshold while

!!!!!!!

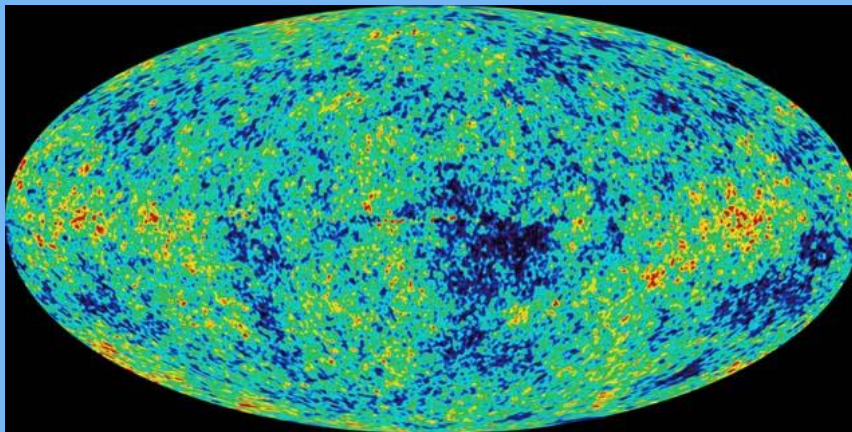

Since then....

Scenario ruled out (??) by:

- CMB (Ricotti, Ostriker, Mack 2007)
- Dwarf-galaxy dynamics (Brandt, 2016; Koushiappas et al. 2016)
- Quasar lensing (Mediavilla 2017)
- X rays from accretion of ISM (Gaggero et al. 2017; Inoue & Kusenko 2017)
- SN dispersions (Zumalcarregui & Seljak 2017)
- Pulsar timing (Schutz & Liu 2017)
- Good taste [[Supergravity inflation (1606.07361,1612.02529); axion inflation (1610.03763; 1704.03464); broken scale invariance (1611.06130,1702.03901);non-thermal histories (1703.04825); trapped inflation (1606.00206); double inflation (1705.06225); axion stars (0609.04724); critical Higgs inflation (0705.04861); contracting Universe (0609.02556)....]]

CMB fluctuations

Ricotti, Ostriker, and Mack (2008): heating of primordial plasma due to accretion onto PBHs leads to unacceptable fluctuations in CMB (by ~ 3 -4 OoMs!!)

How does the CMB probe PBHs?

- PBHs accrete primordial plasma
- Accreted gas gets heated
- Heated gas radiates
- Radiation heats plasma → spectral distortions
- Radiation also affects ionization balance
 - changes recombination history
 - affects CMB power spectra

Our work

(Ali-Haimoud&MK 2017)

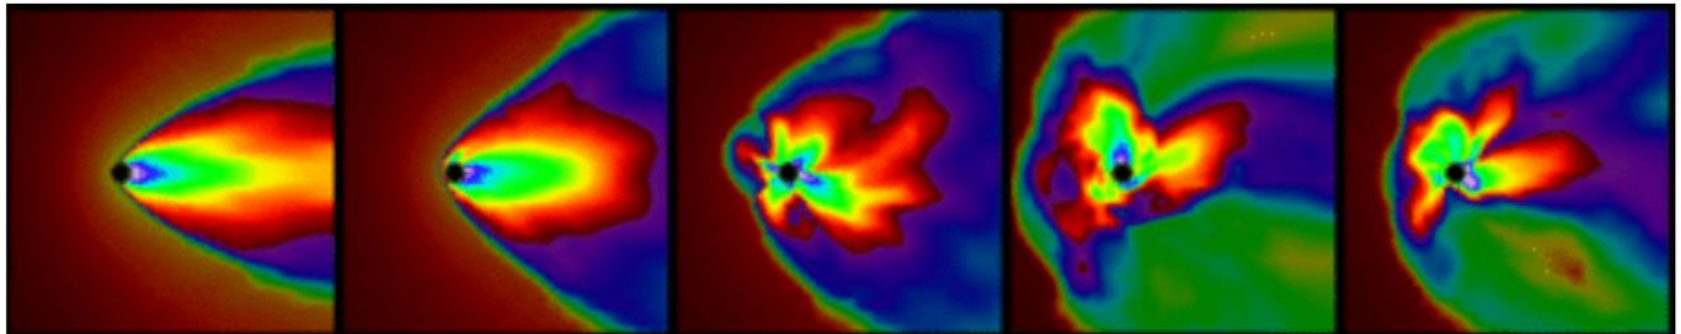

- first-principles calculation
- Given many uncertainties/complications, make simplest but most robust assumptions
- seek *bound*, not best estimate
- Self-consistently include DM-baryon relative velocities

Baryon-dark matter relative velocity

Baryons and dark matter have large-scale relative motions
(see e.g. Tseliakhovich & Hirata 2010 for effect on small-scale structure)

- before recombination $v_{\text{rel}} \approx 30 \text{ km/s} \approx 5 c_s$
- after recombination: baryons become cold like DM. $v_{\text{rel}} \propto 1/a$

Ricotti et al. 2008 assumed $v_{\text{rel}} \approx 4 \text{ km/s} \lesssim c_s$

Ruffert's website

Baryon-dark matter relative velocity

Simple fudge (à la Bondi-Hoyle): $c_s \rightarrow (c_s^2 + v_{\text{rel}}^2)^{1/2}$

in the simple Bondi case: $L \propto \dot{M}^2 \propto \frac{1}{(c_s^2 + v_{\text{rel}}^2)^3}$

$$\langle L \rangle \propto \left\langle \frac{1}{(c_s^2 + v_{\text{rel}}^2)^3} \right\rangle \approx \frac{1}{c_s^3 \langle v_{\text{rel}}^2 \rangle^{3/2}}, \quad \langle v_{\text{rel}}^2 \rangle \gg c_s^2$$

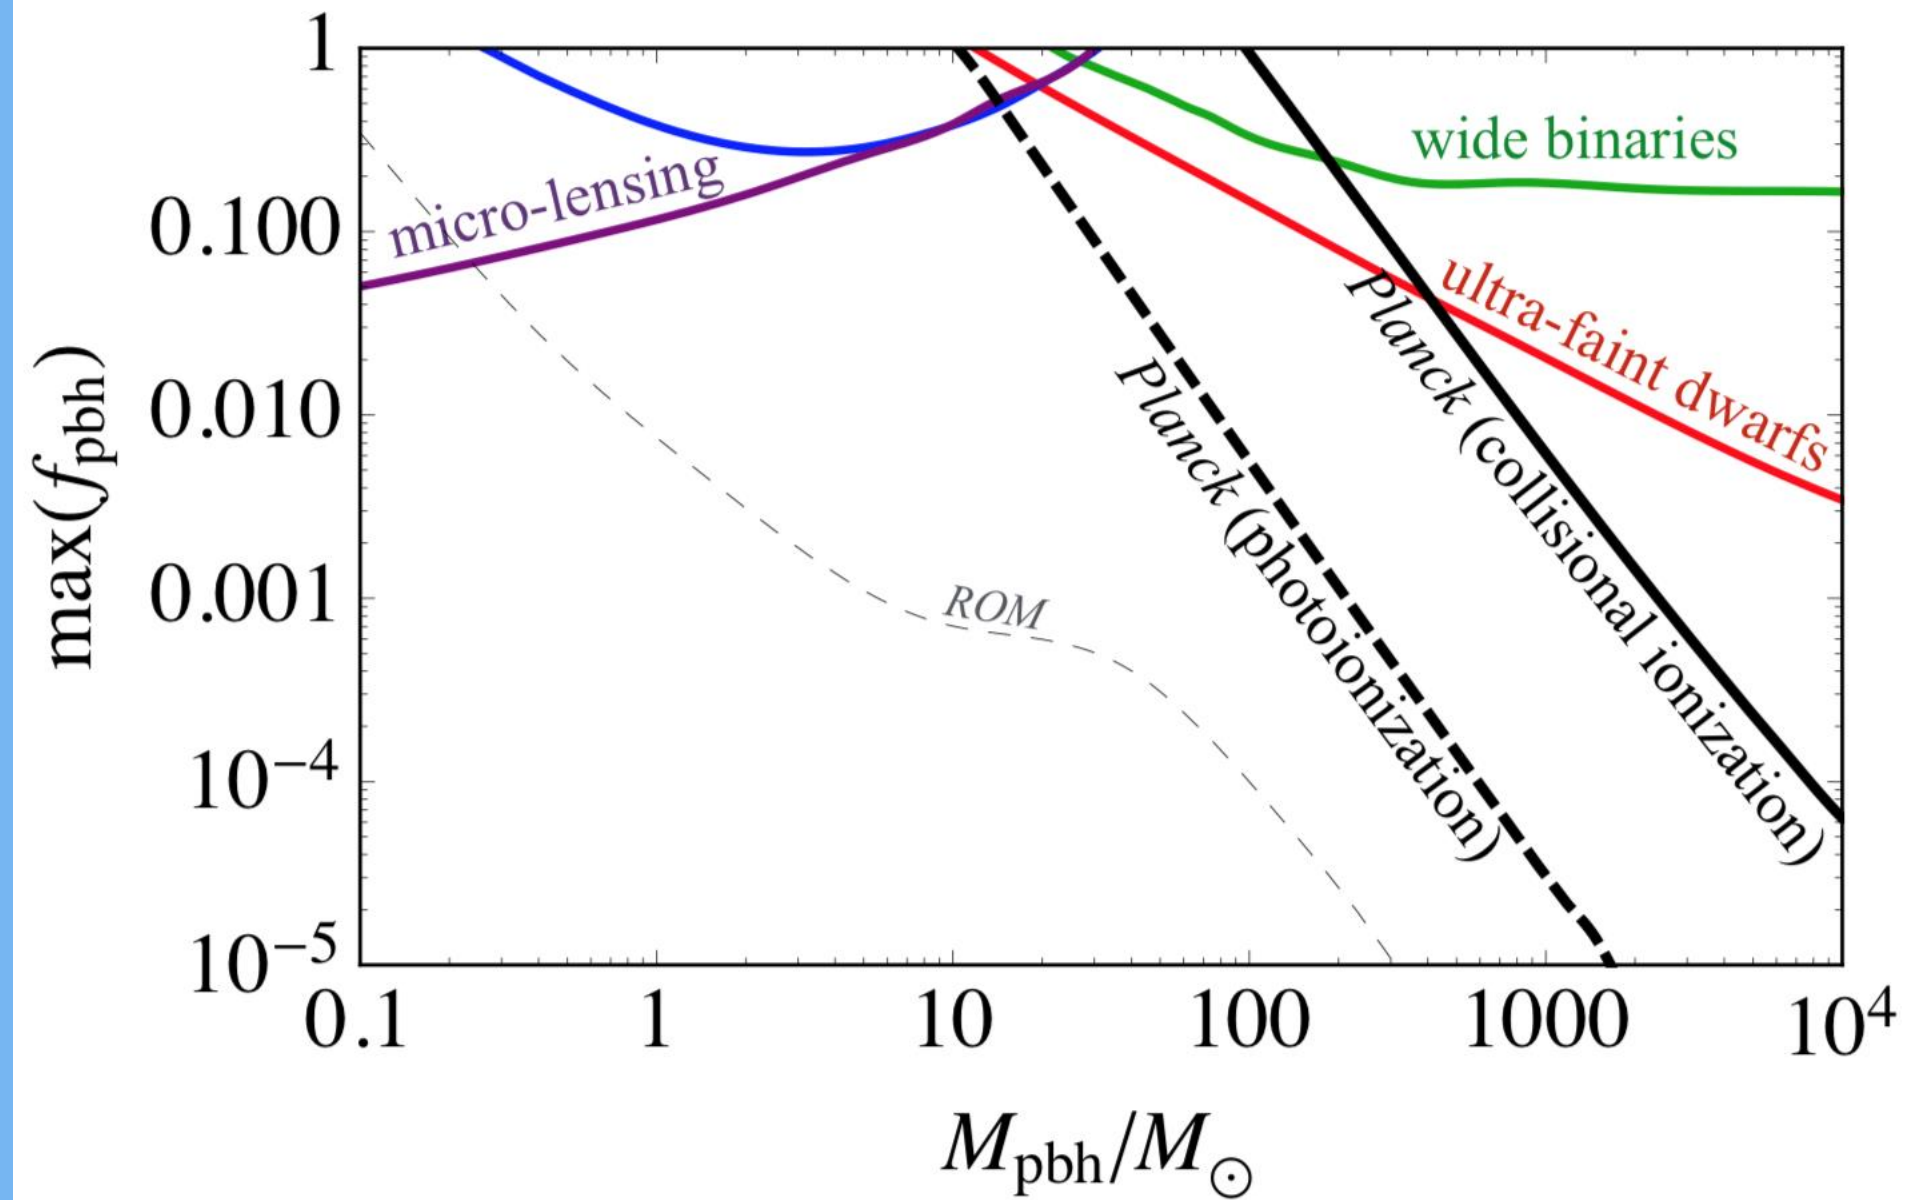

$$\frac{\langle L \rangle}{L(v_{\text{rel}} = 0)} \sim 10^{-2}$$

See also Horowitz 2016, Aloni, Blum & Flauger 2017

Notes: (1) detailed suppression is not highly relevant: average luminosity is dominated by subsonically accreting BHs.

(2) there are small-scale motions due to non-linear clustering.

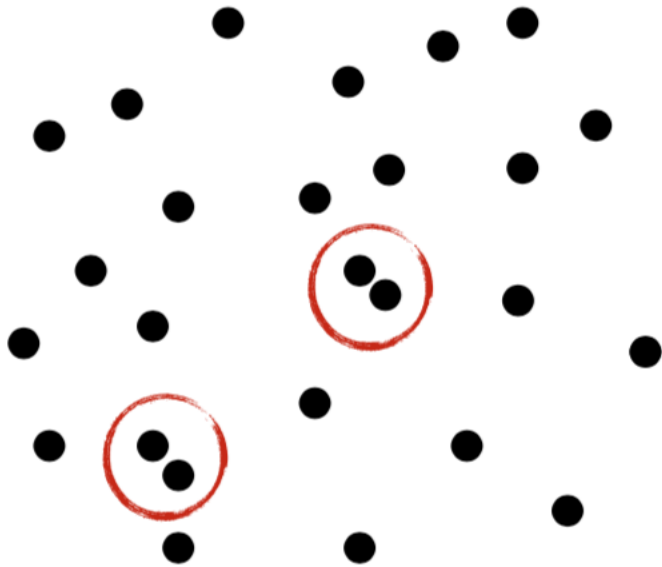

We do not account for those.

Does LIGO rule out PBH dark matter?

(Ali-Haimoud, Kovetz, MK 2017)

Basic idea: Nakamura, Sasaki, Tanaka & Thorne 1997

On small enough scales, PBHs are randomly distributed (or maybe not quite!)

Some PBH pairs happen to be close enough that they decouple from the Hubble flow deep in the radiation era.

As they fall towards one another, torqued by other PBHs result in a non-zero (but small) angular momentum

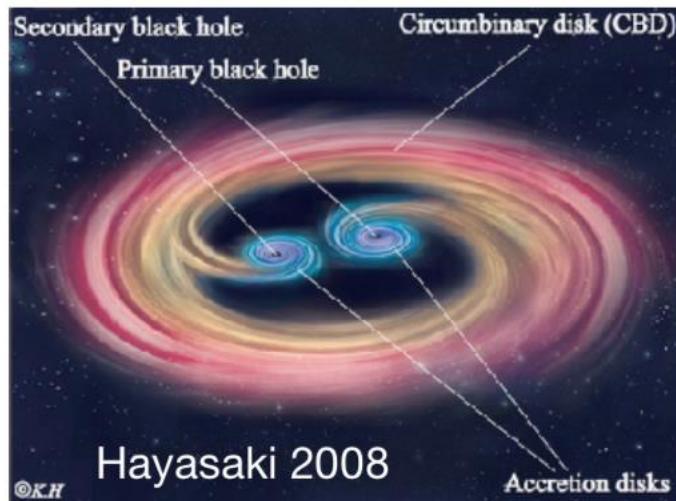

Inspiral through GW radiation, some merge at the present time.

Do binaries that form at $z \sim 10^4 - 10^5$ evolve **only** through GW radiation until the present time?

- Gravitational interactions with other PBHs and rest of dark matter

Using simple analytic estimates of the properties of the first structures, we found that torques due dark matter (PBHs or WIMPs) do not significantly affect PBH binaries.

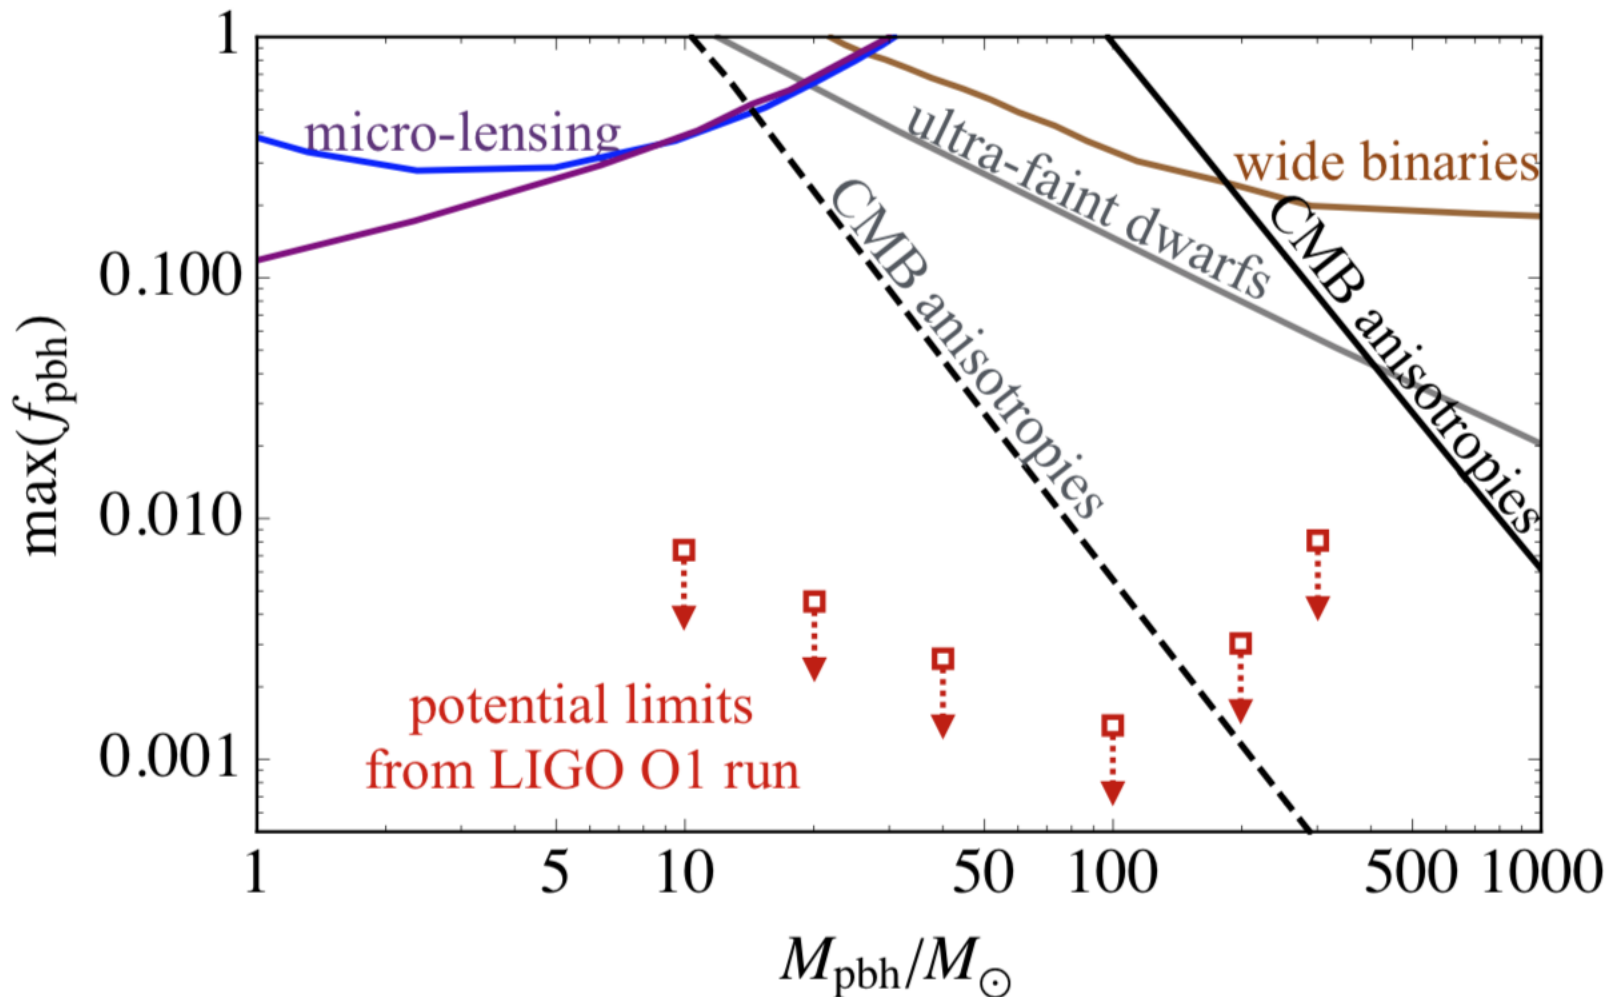

- Exchange of energy and angular momentum with accreting baryons

Most uncertain piece. Estimated that torques could be marginally relevant. Subject of active research (e.g. Tang, Haiman & MacFadyen 2018).

Does LIGO rule out PBH-dark matter?

Probably but more checks are needed

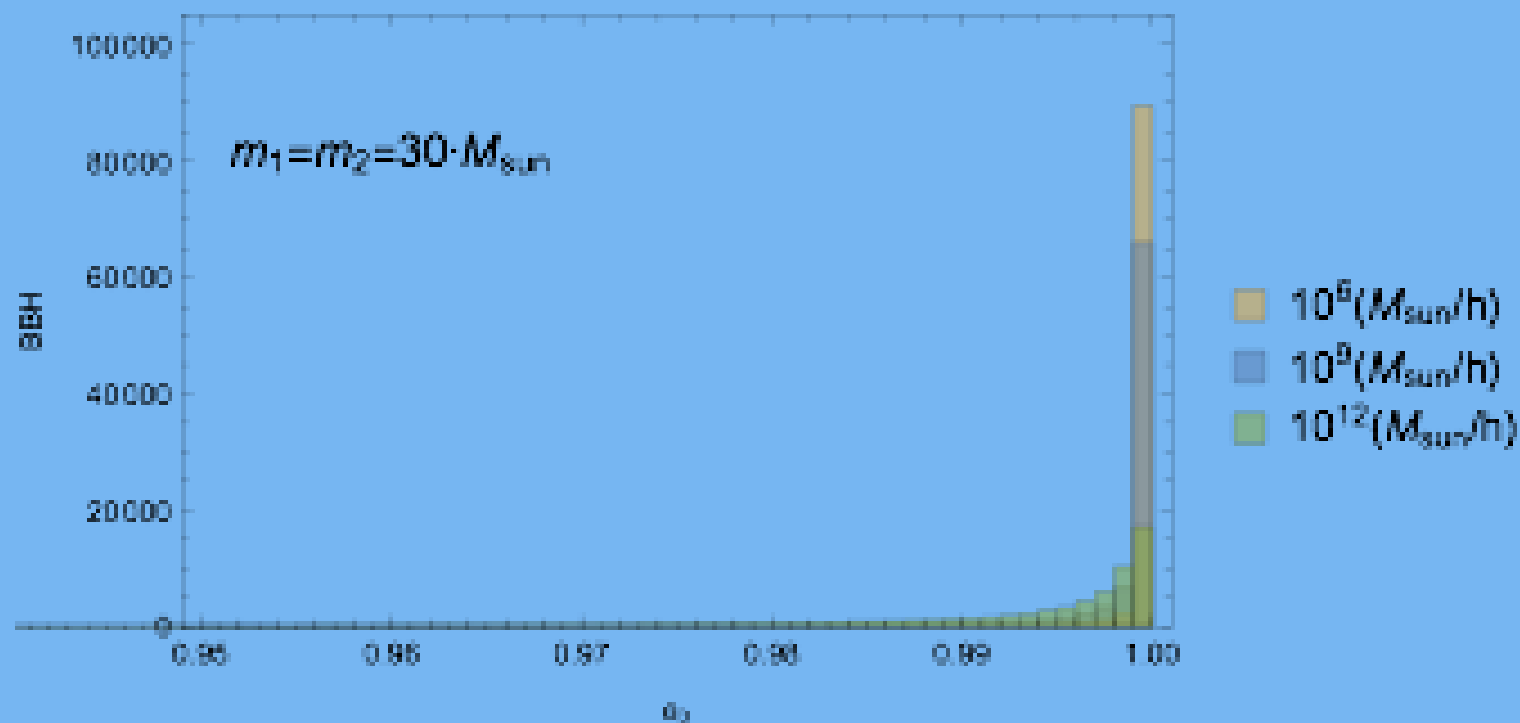

How to test PBH DM hypothesis?

- BBH mass spectrum
- BBH eccentricity No EM/neutrino counterparts!
- Clustering with DM
- Stochastic GW background
- Lensing echoes of fast radio bursts

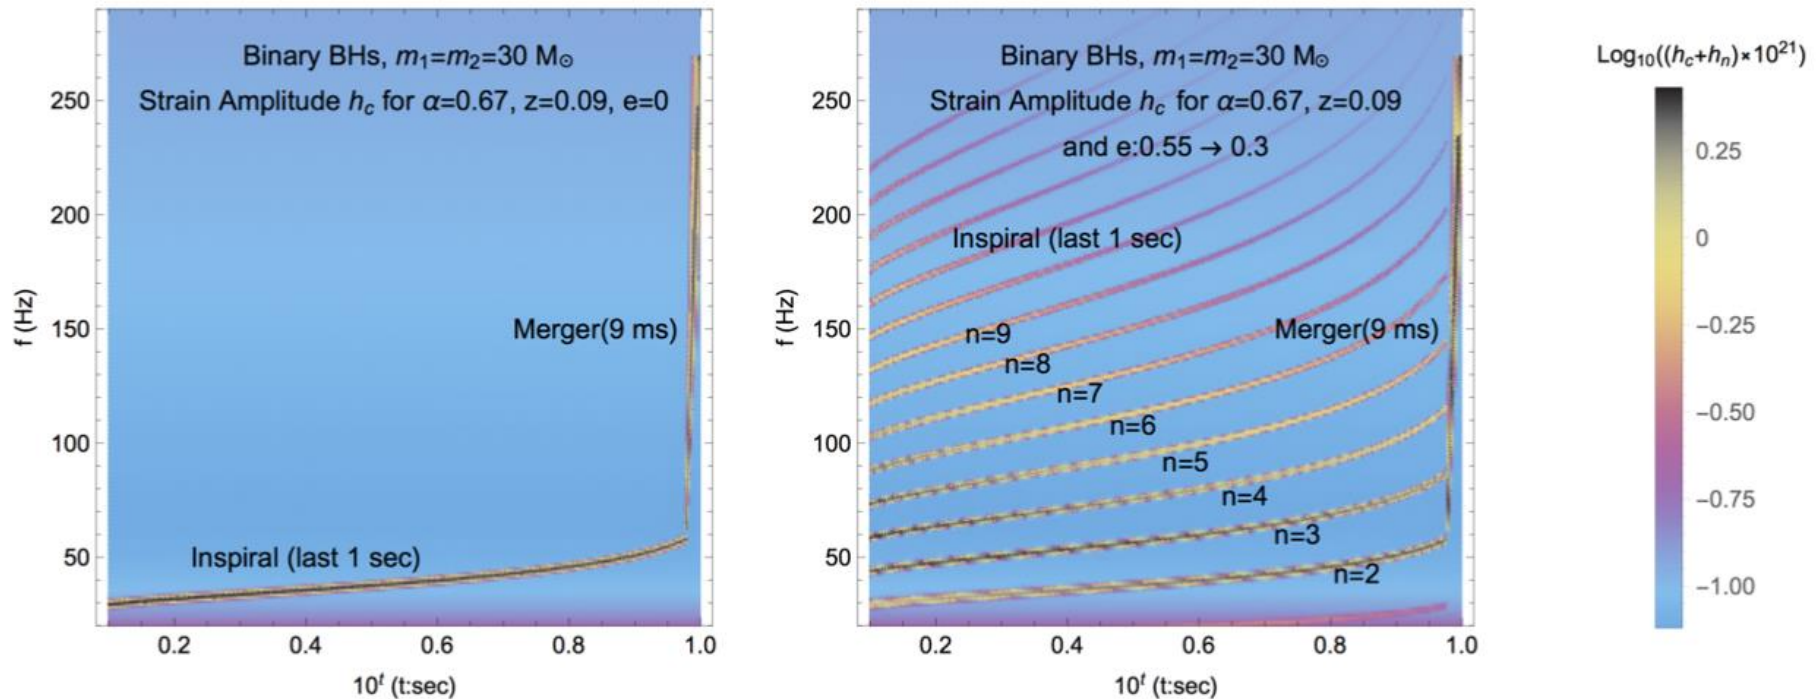

Given current LIGO rate, expect
perhaps $\sim 20,000$ more BBH
mergers in next decade!!

PBH binaries have high initial eccentricities:

see many more modes of grav. waves

~1 such event in LIGO; ~10 in Einstein Telescope

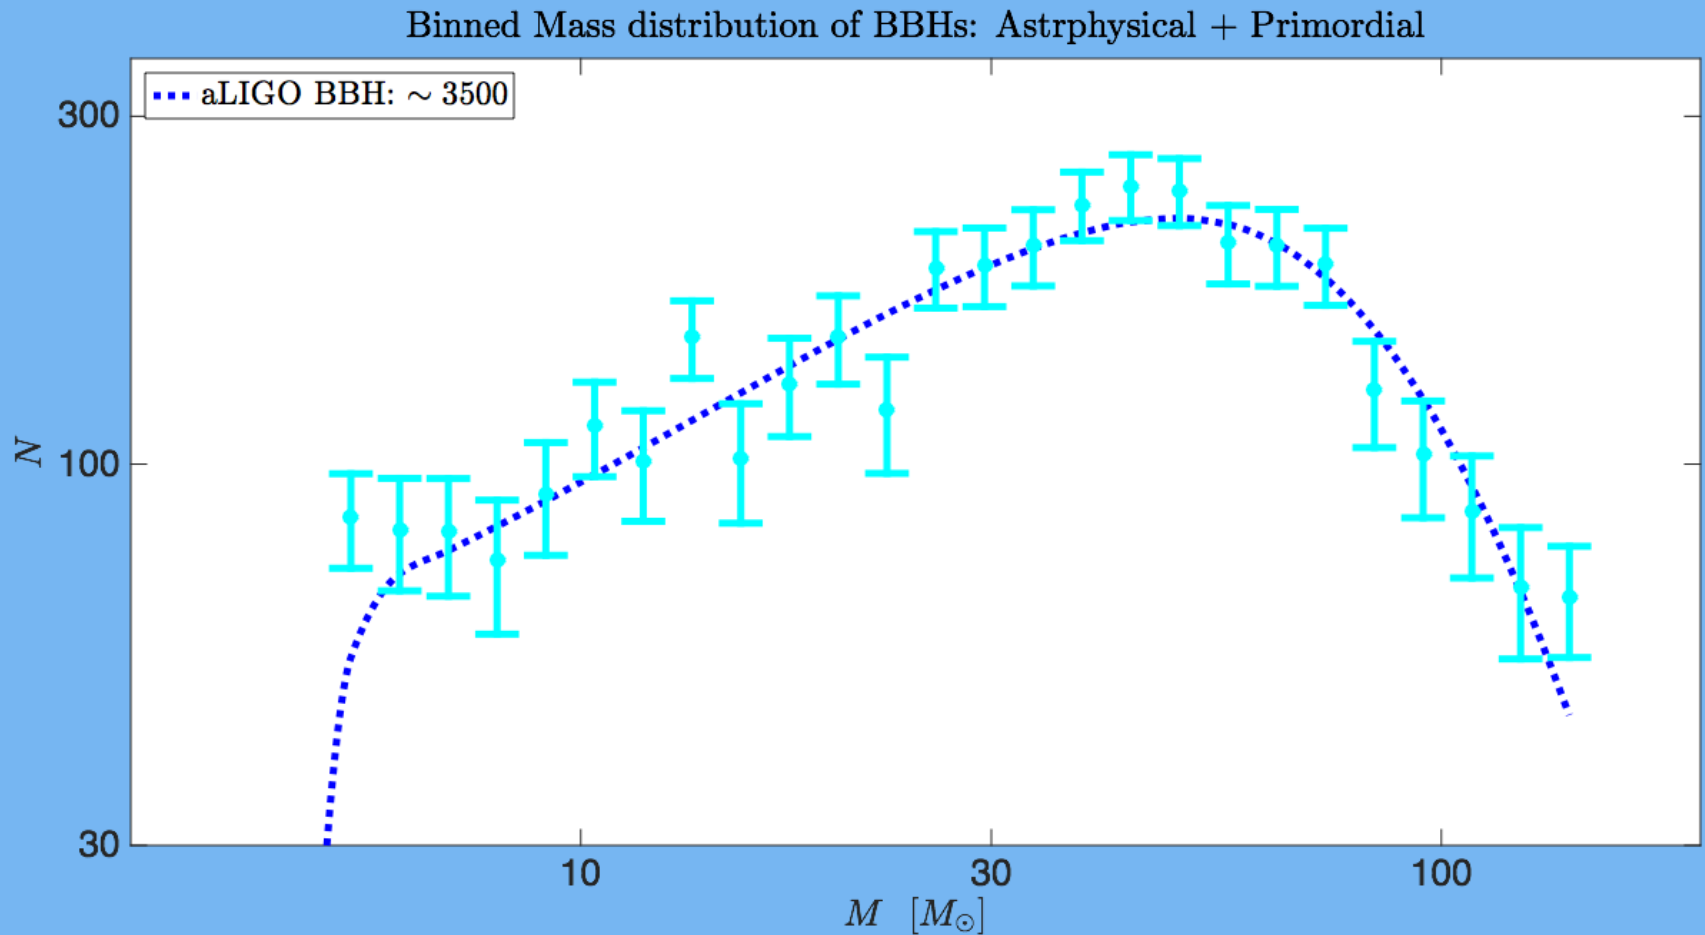

Cholis, Ali-Haimoud, Bird, Munoz, MK,

With Dark Matter PBHs:

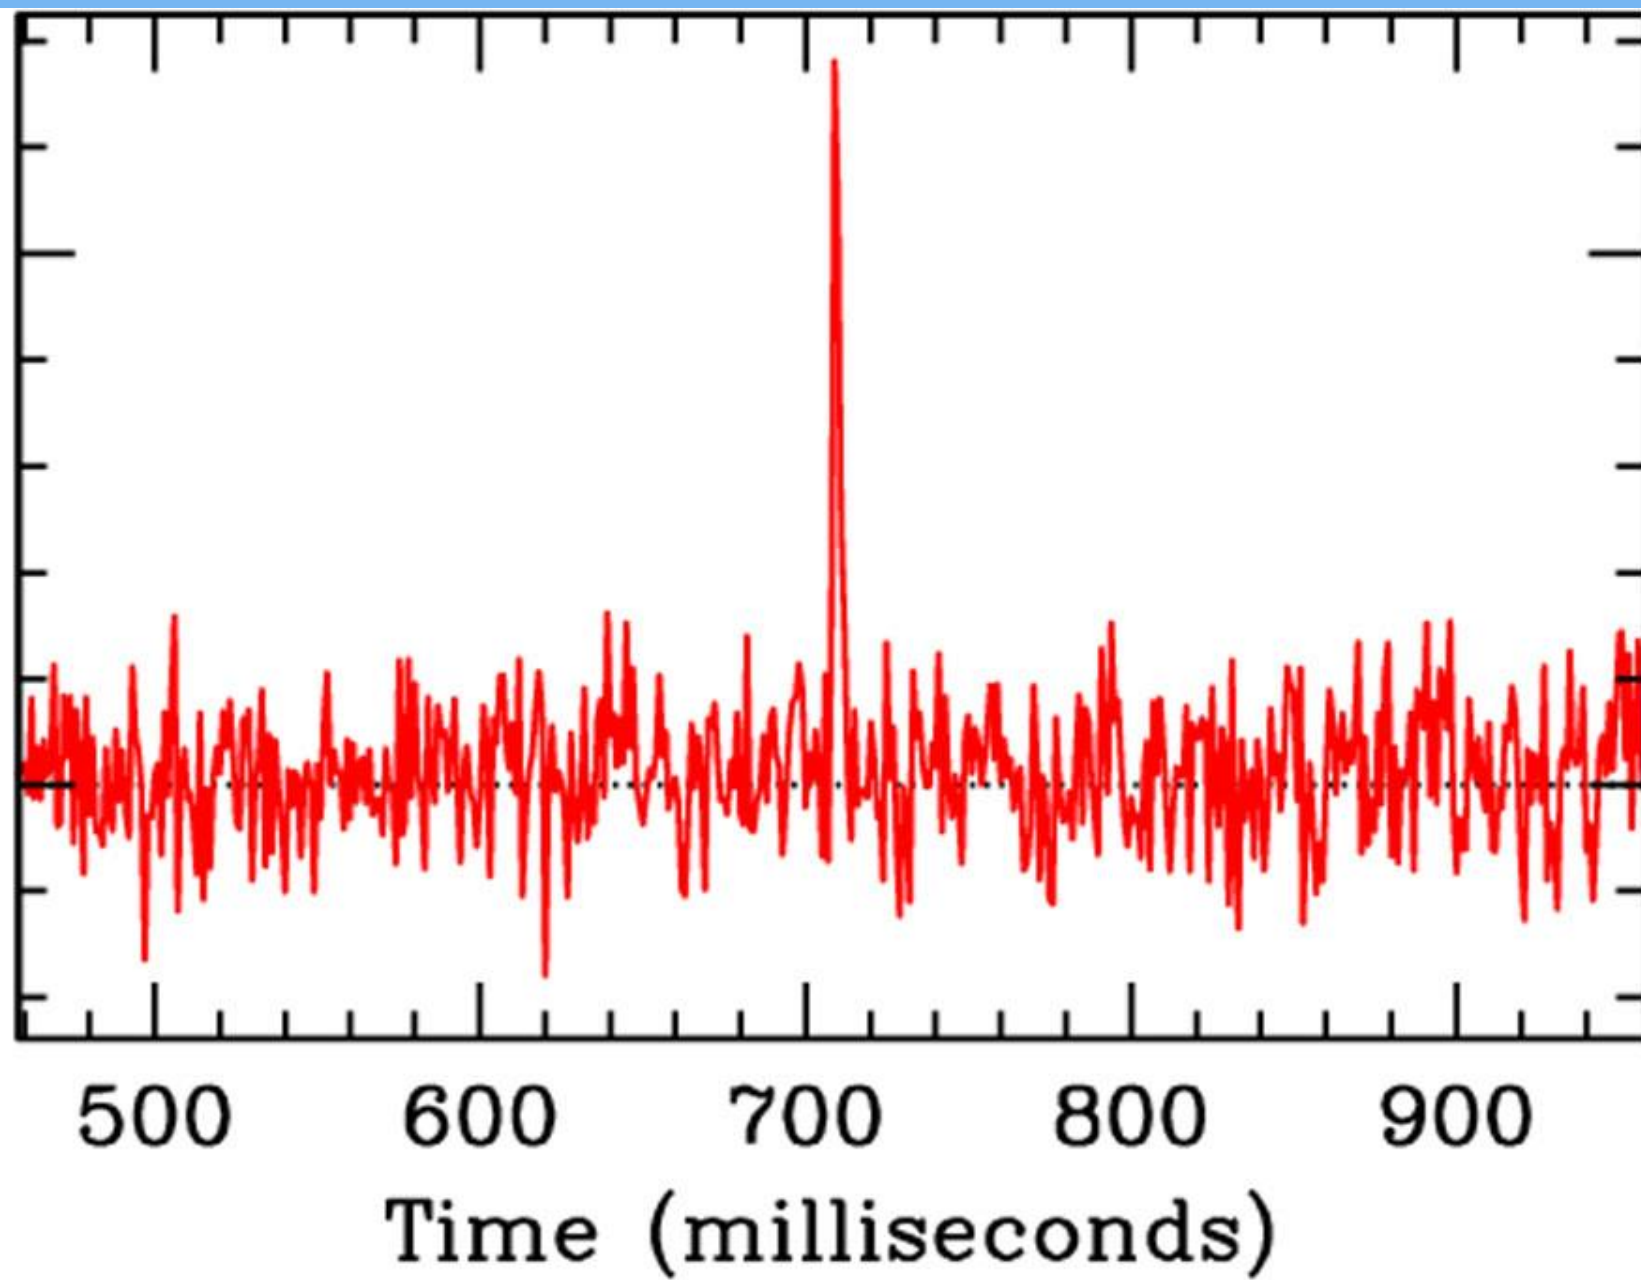

Lensing of Fast Radio Bursts by Compact Objects

Munoz, Kovetz, Dai, MK, 1605.00008

- FRBs = $<$ millisecond \sim GHz radio bursts
- $\sim 10,000$ on sky per day
- Large dispersion measures imply cosmological distances
- Forthcoming experiments (e.g., CHIME) should detect thousands

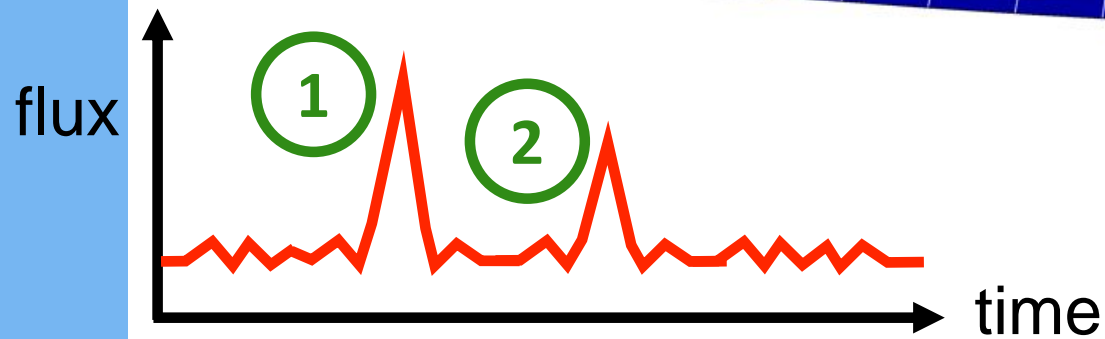

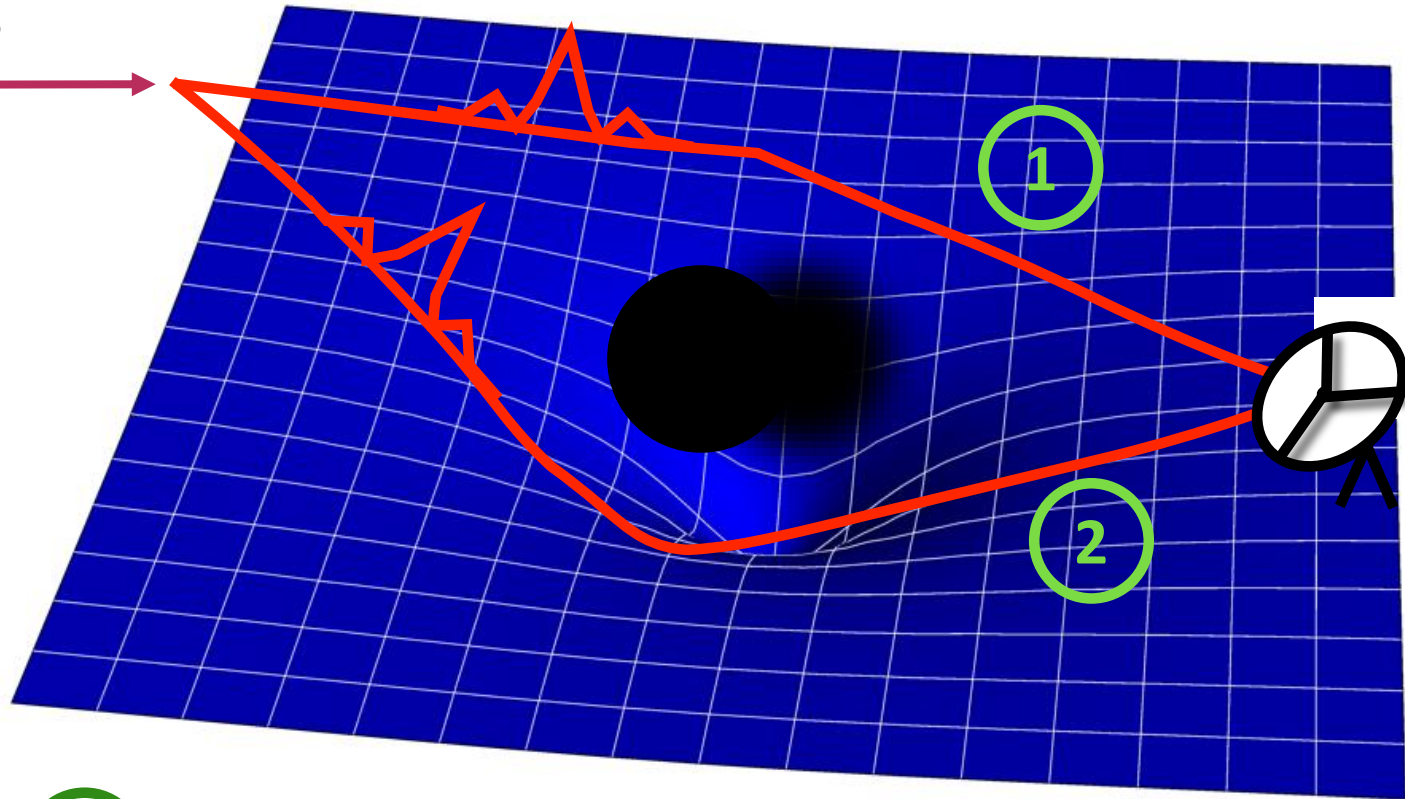

Intensity

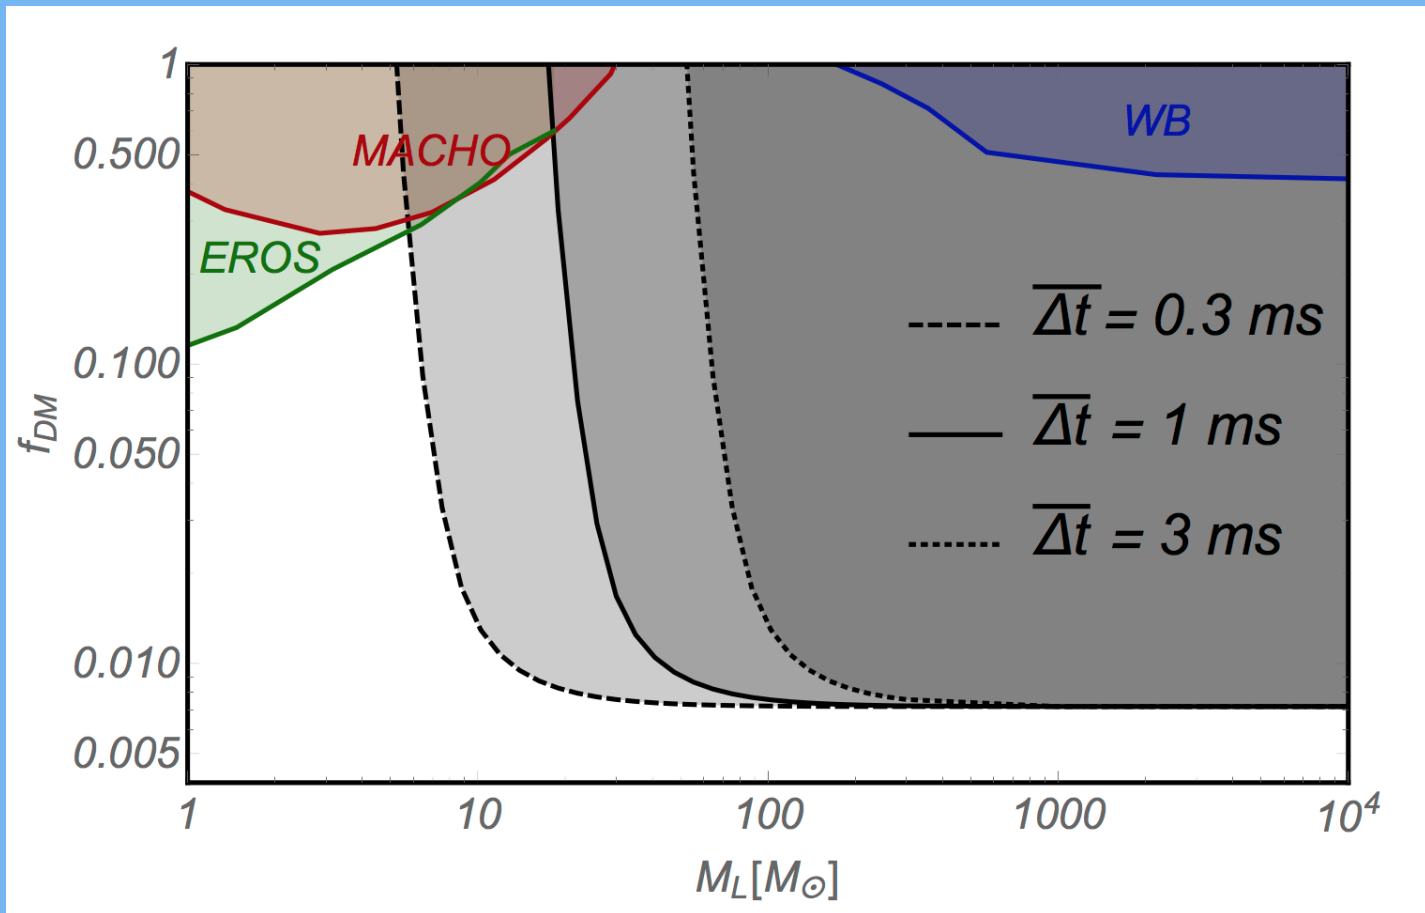

FRB Lensing

(Muñoz, Kovetz, Dai, Kamionkowski, PRL 117 (2016))

Source FRB

Images separation (\sim nano-arcsec) too small to be detected,
but there can be a $>$ ms time delay

In progress

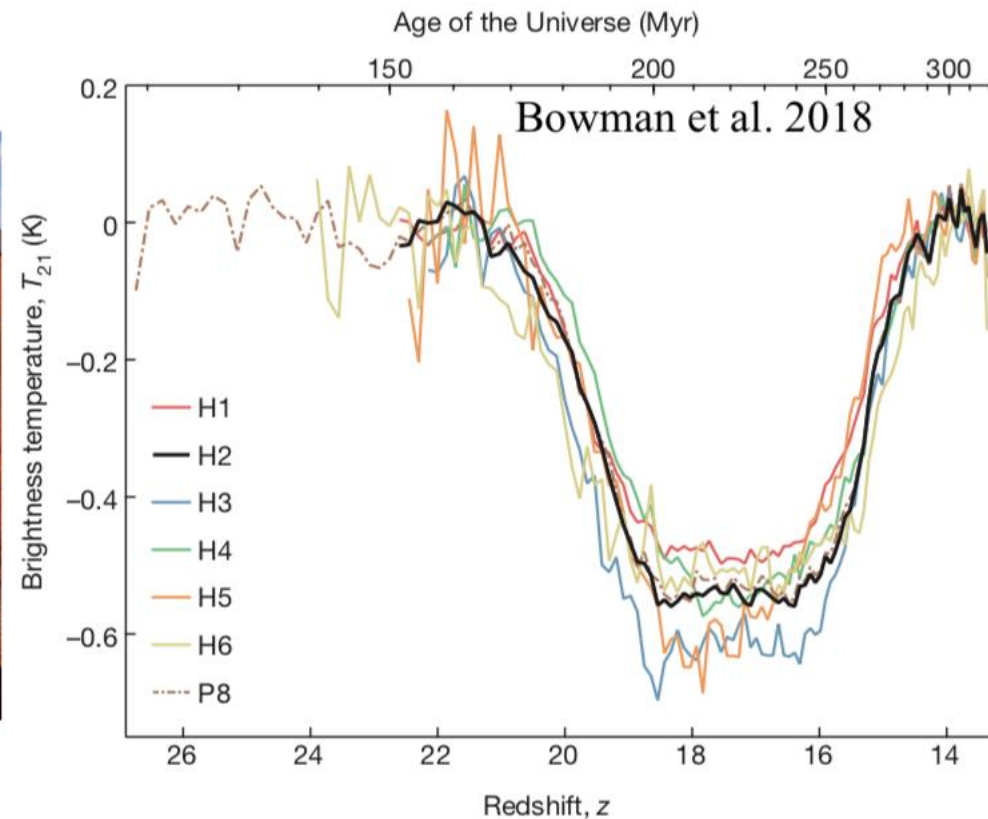

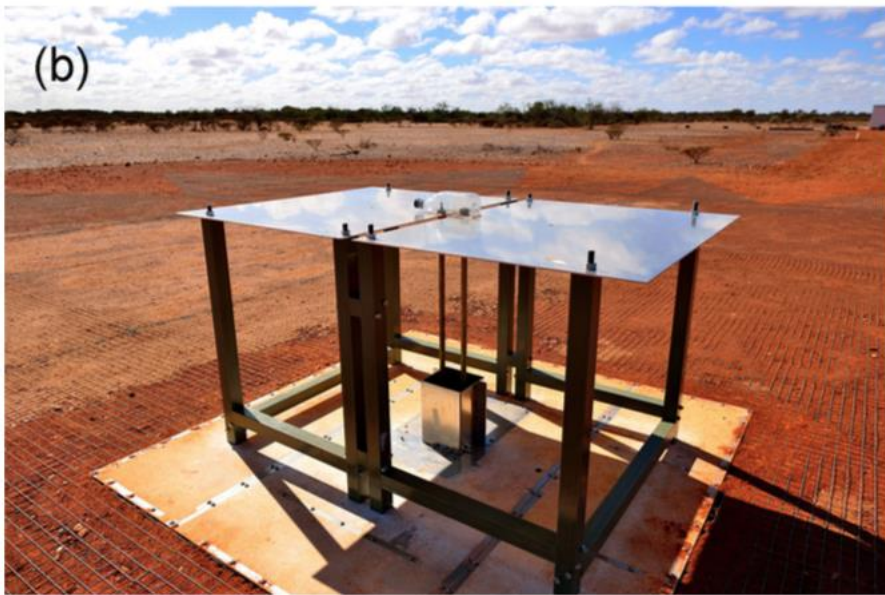

Can also seek echoes in gamma-ray-
burst light curves

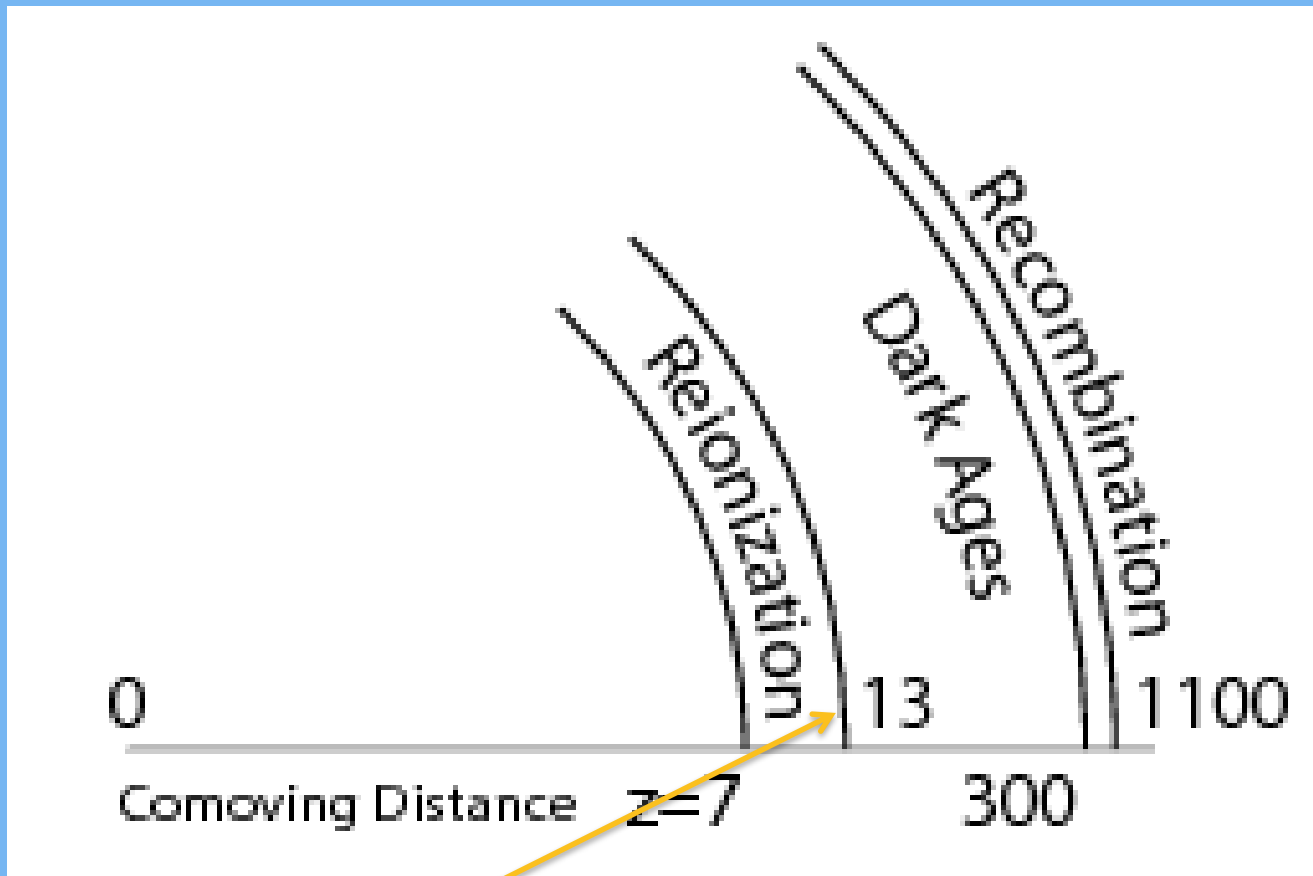

(Ji, Kovetz, MK)

Baryon—DM interactions from cosmic dawn?

(EDGES: Bowman et al. Nature 2018; Barkana, Nature 2018)

February 2018

Lots of neutral hydrogen

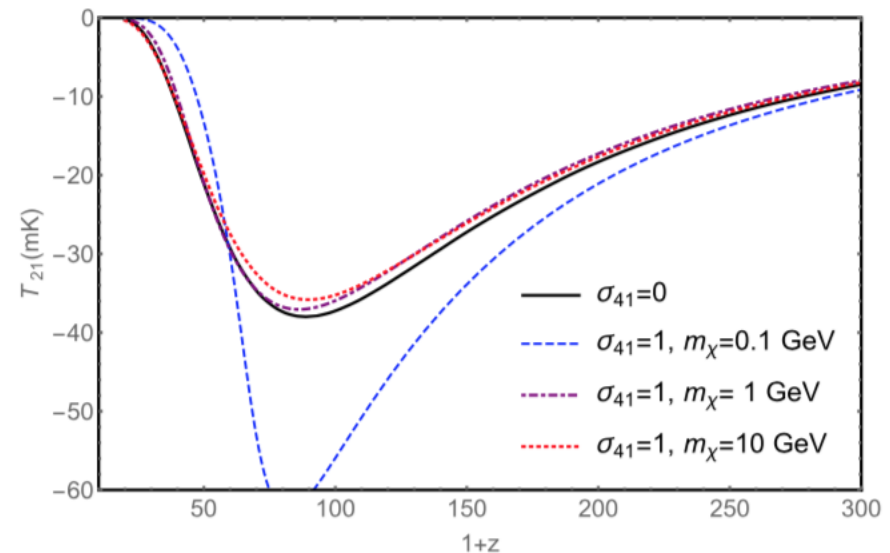

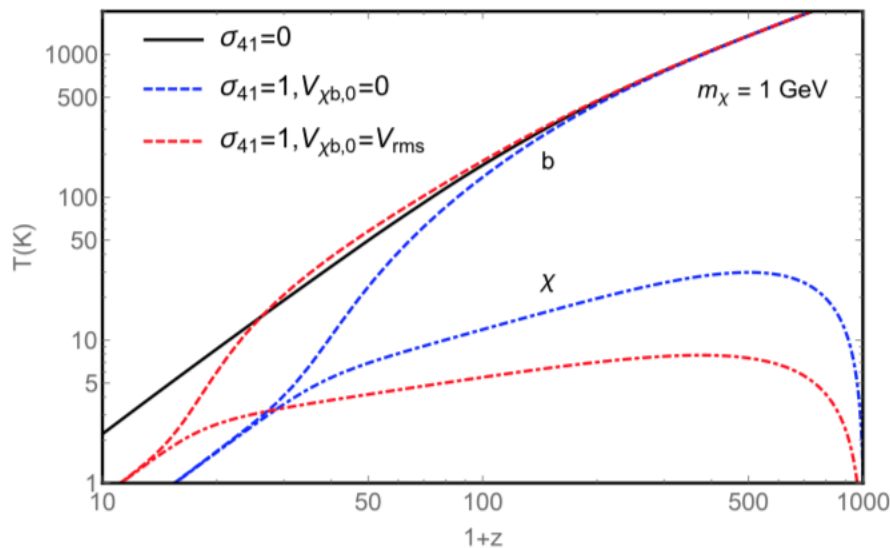

If DM-baryon interactions exist, they can mediate heat exchange between baryons and DM (Dvorkin, Blum, MK 2014)

$$\frac{dT_\chi}{da} = -2\frac{T_\chi}{a} + \frac{2\dot{Q}_\chi}{3aH}, \quad \frac{dT_b}{da} = -2\frac{T_b}{a} + \frac{\Gamma_C}{aH}(T_\gamma - T_b) + \frac{2\dot{Q}_b}{3aH}$$

Tashiro, Kadota, Silk 2014: DM can act as heat sink and cool neutral hydrogen in dark ages

Munoz, Kovetz, Ali-Haïmoud 2015: included heating due to baryon-DM relative velocities and pointed out implications for global 21-cm signal

$$\dot{Q}_b = F(\mathbf{V}_{\chi b})(T_\chi - T_b) - \frac{\rho_\chi}{\rho_m} \frac{m_\chi m_b}{m_\chi + m_b} \frac{d}{dt} \left(\frac{1}{2} V_{\chi b}^2 \right)$$

Issues/concerns/question:

Systematics (e.g., beam uncertainties)?

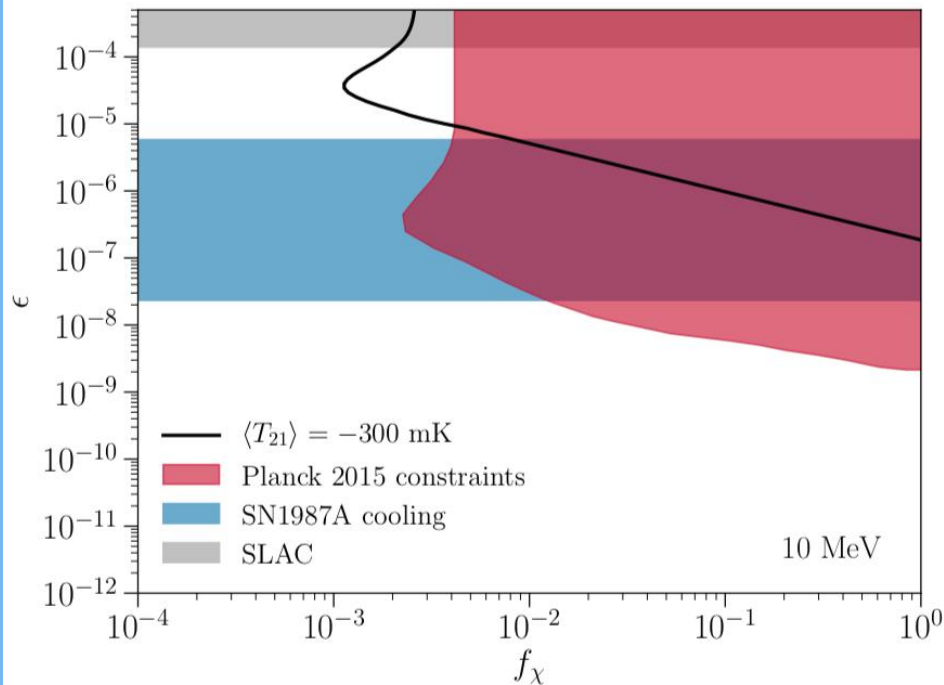

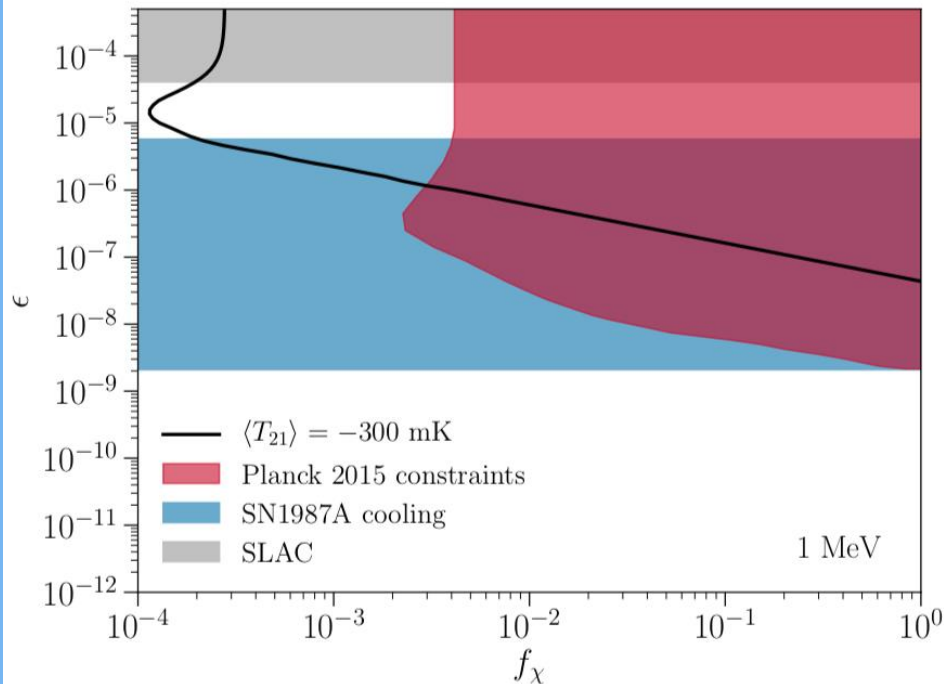

Required DM properties hard to come by
theoretically (e.g., Munoz & Loeb; Berlin et al., Barkana et al.;
Slatyer & Wu; Boddy et al. in prep; Kovetz et al., in prep)

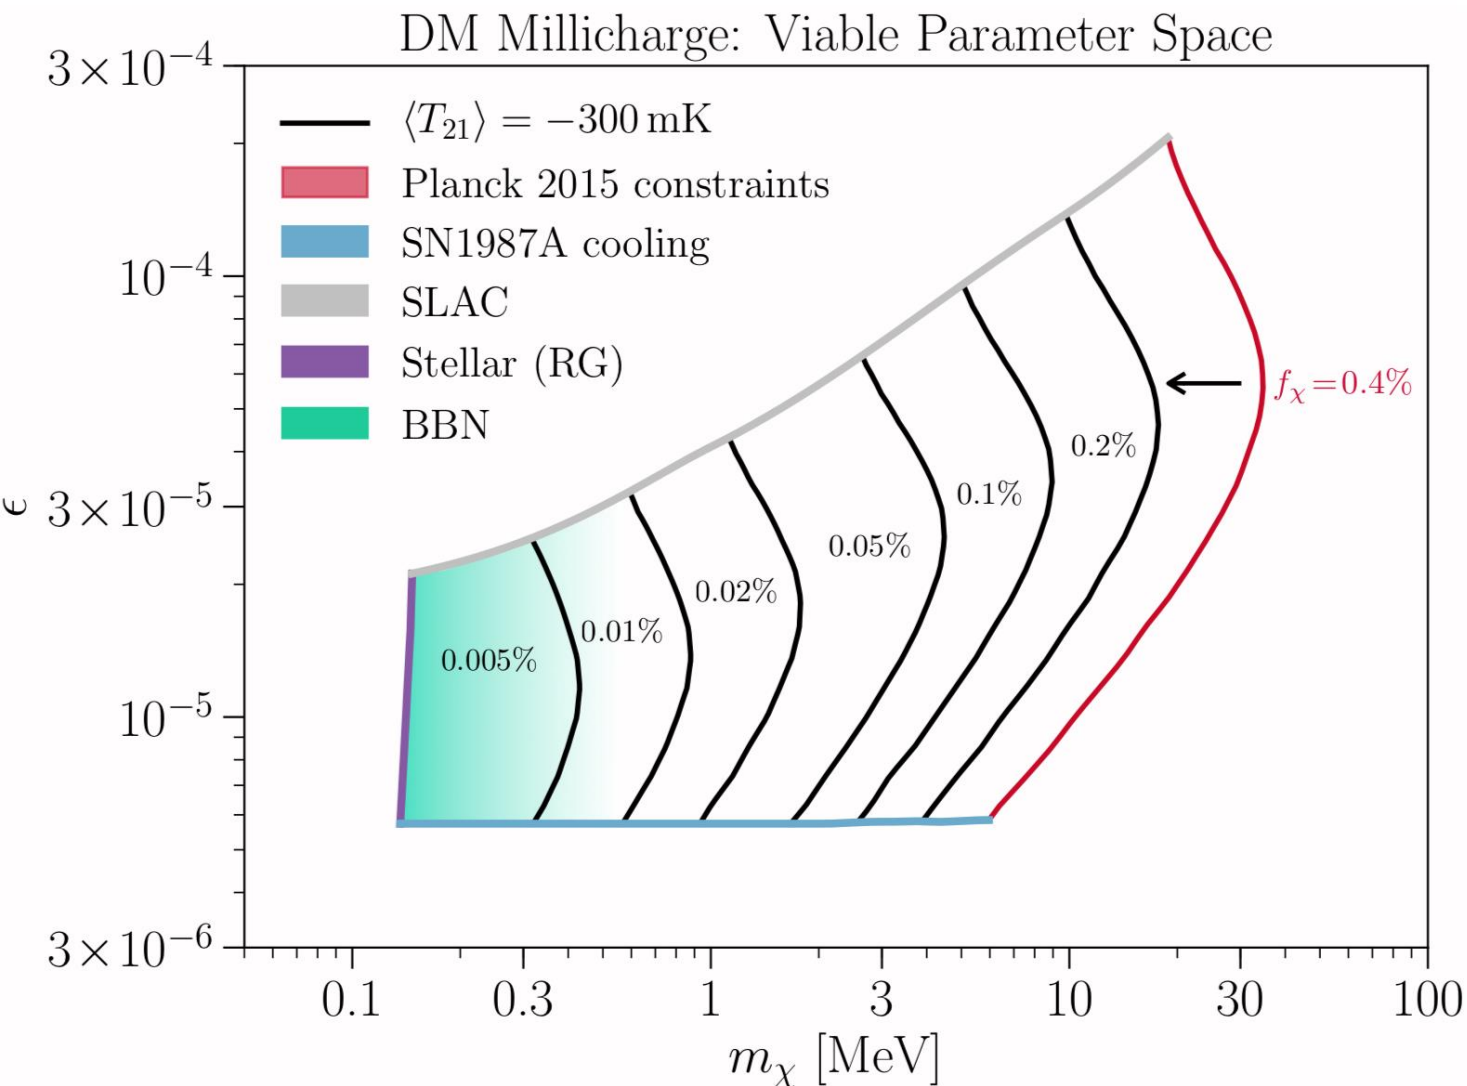

Basic issue: CMB constraints (Dvorkin, MK, Blum 2013;
Boddy&Gluscevic 2017; Slatyer-Wu 2018; Boddy et al. in prep) **require**
 $\sigma \propto \frac{1}{v^4}$ but required keV -- 100 MeV mass range
constrained by SN1987 and stellar cooling. May still
be window where only <1% of DM interacts

New constraints for millicharged DM!

(Boddy, Gluscevic, Poulin, Kovetz, MK, Barkana, any day now)

Kovetz, Poulin, Gluscevic, Boddy, Barkana, MK, any day now)

Parameter space for millicharged-DM explanation for EDGES *very* constrained, but might account for $\sim 2\sigma$ discrepancy between CMB and BBN baryon densities

Dark-matter decay and line- intensity mapping

(Creque-Sarbinowski & MK, arXiv:1806.11119)

Intensity mapping

(review: Kovetz et al. 1709.09066)

Measure sky brightness of some emission line as function of angular position and frequency (a proxy for distance)
→ 3d distribution of emitters

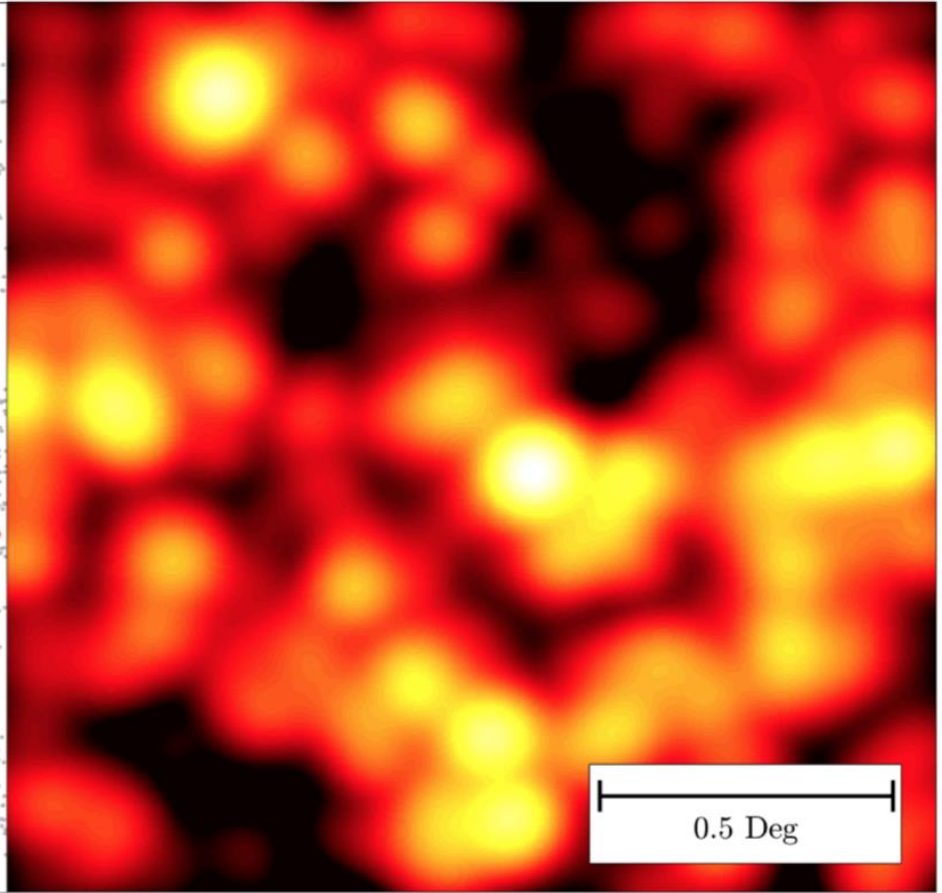

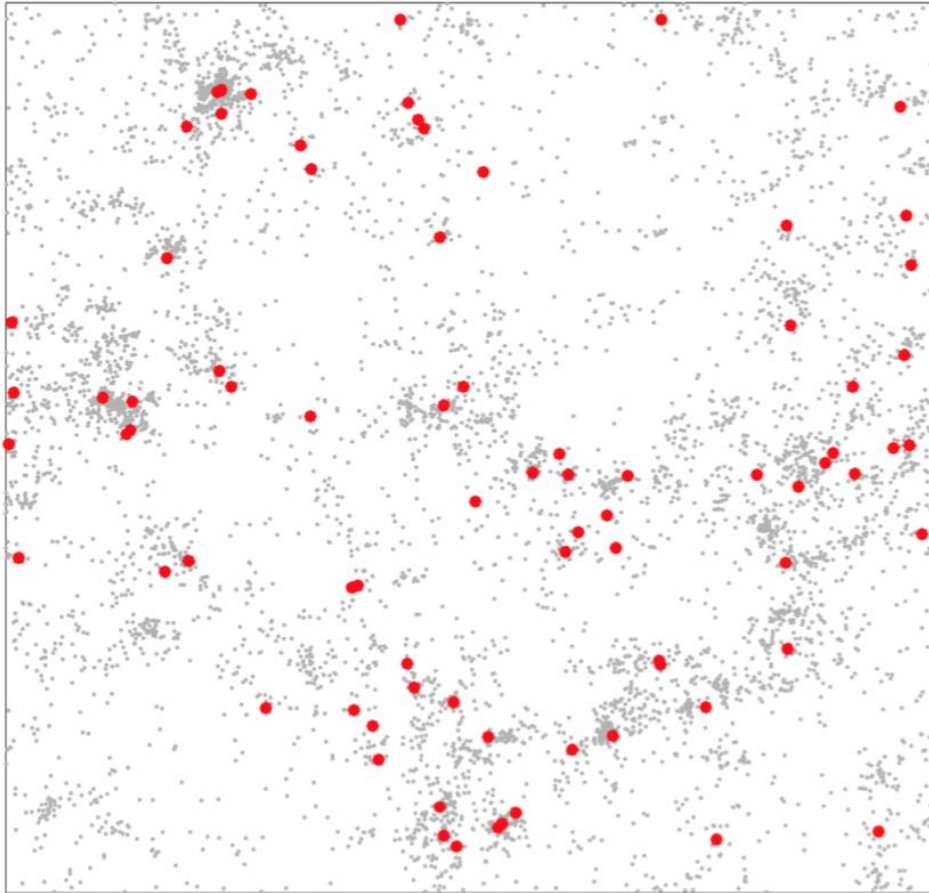

Fig credit: Patrick Breysse

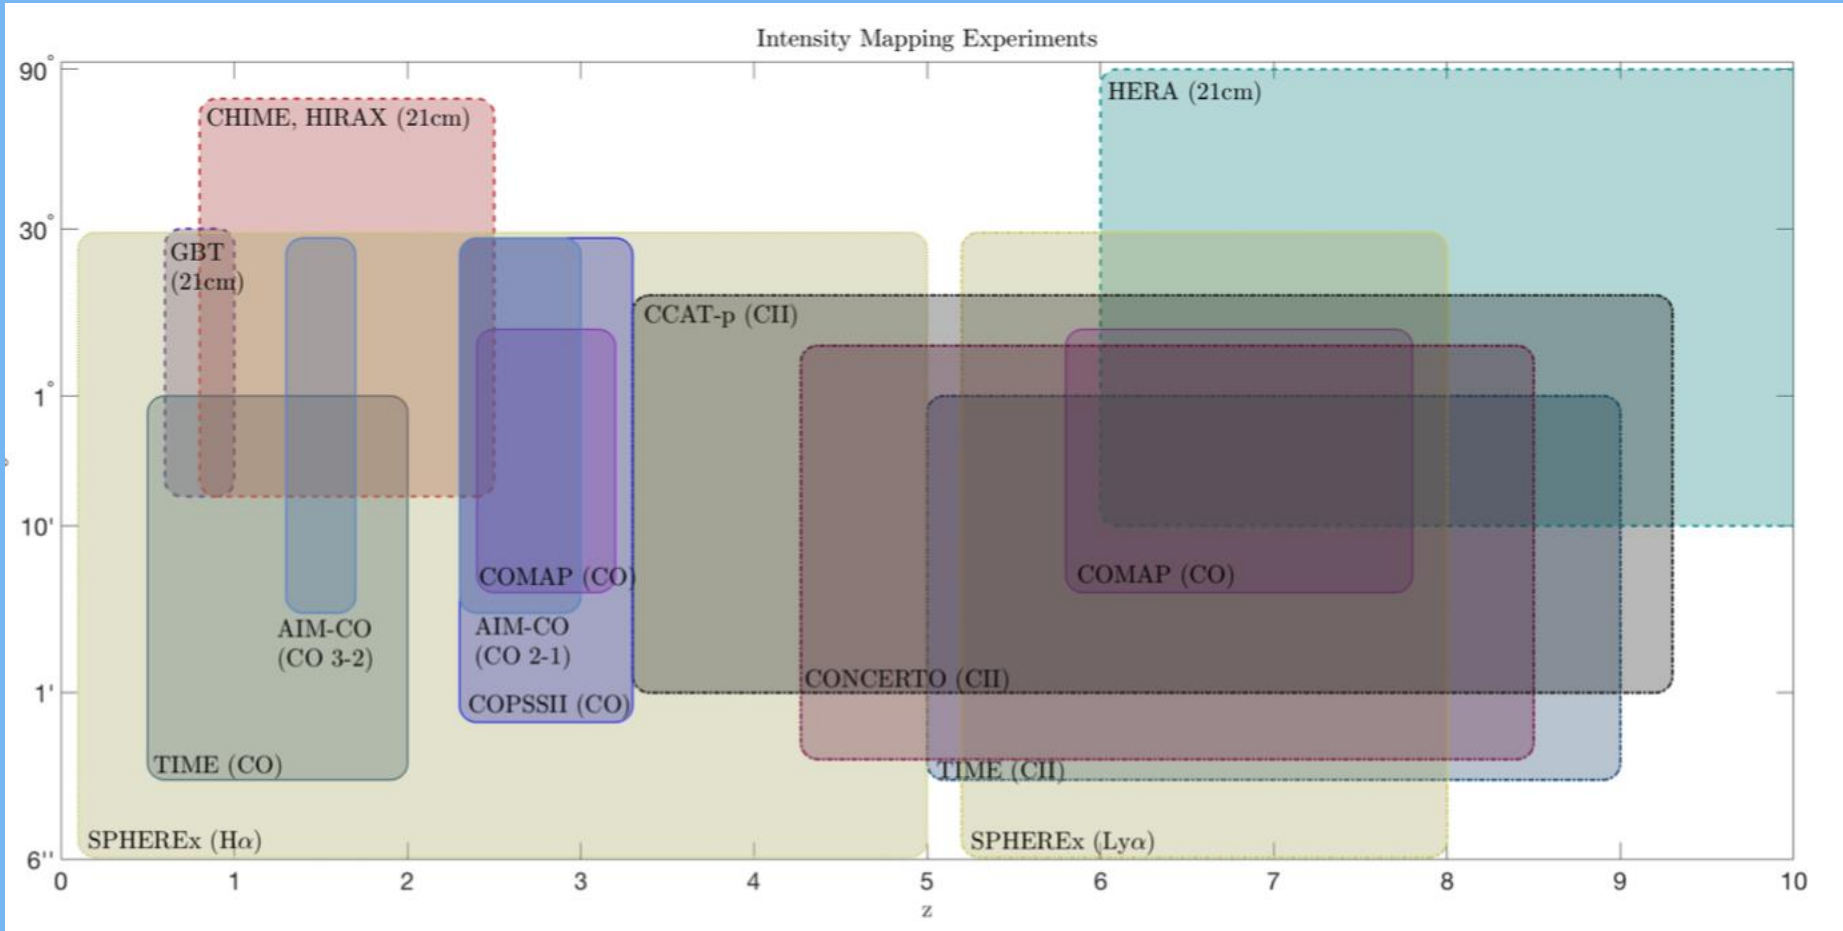

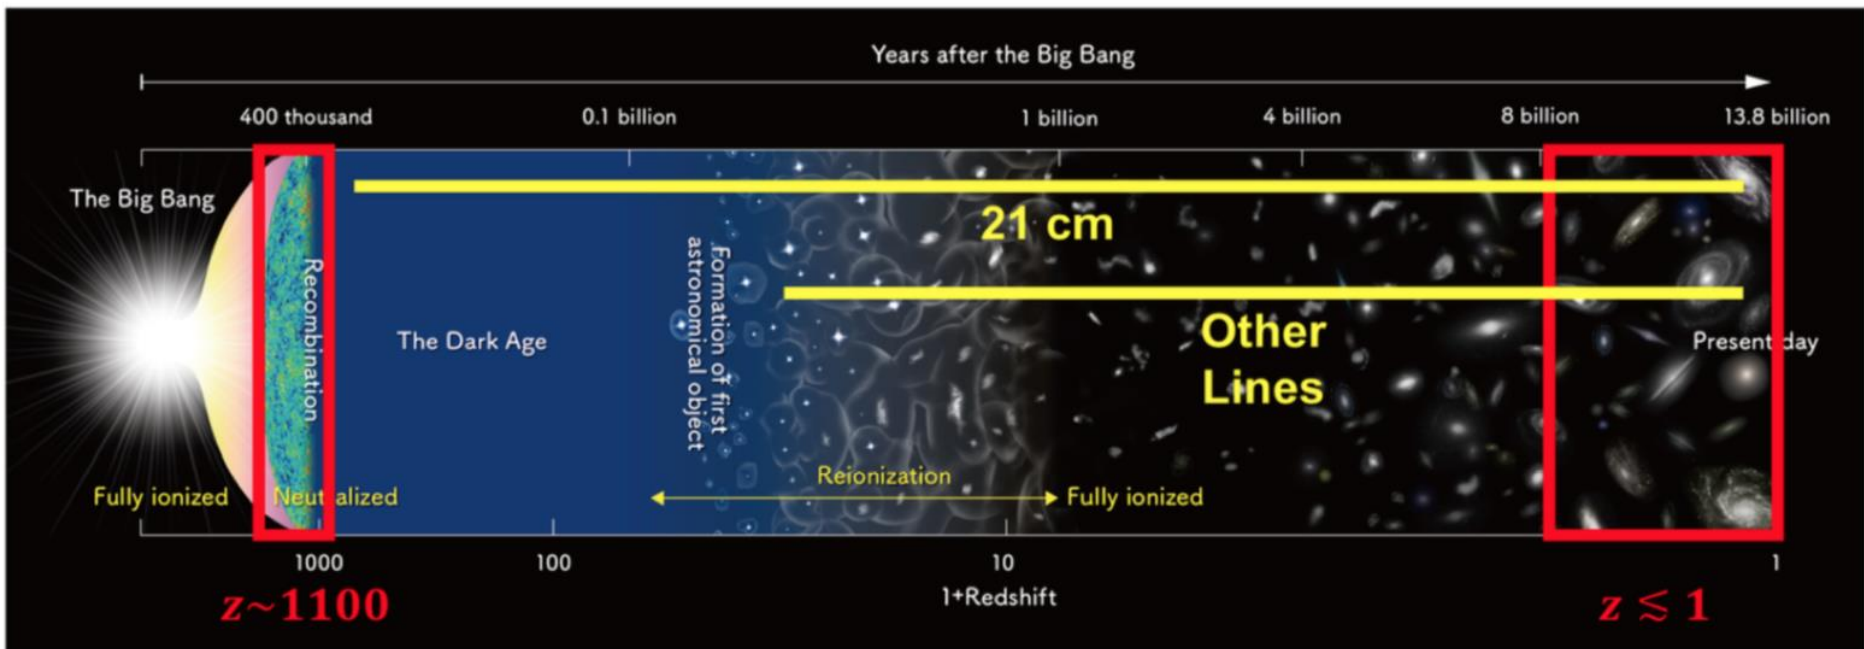

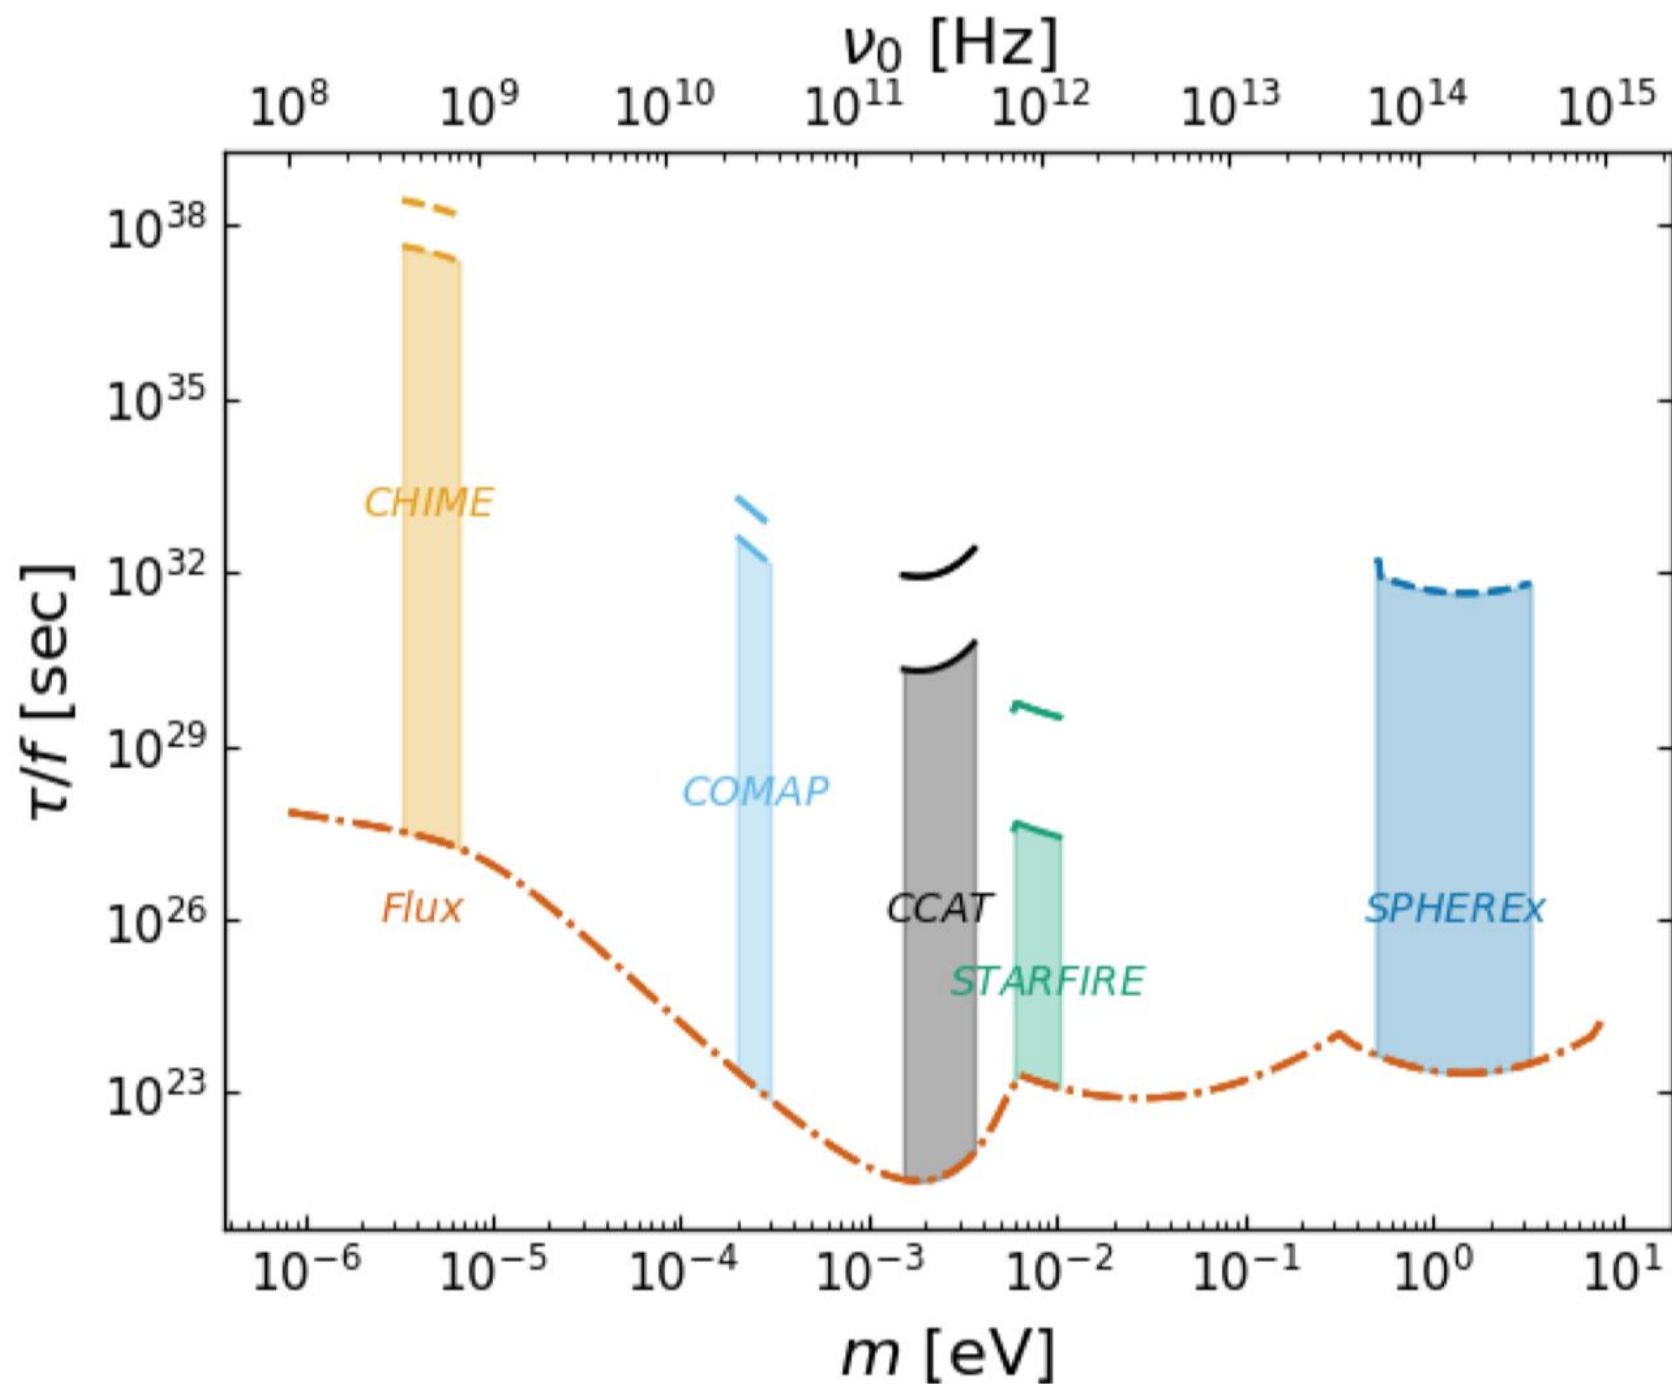

Fig. from Patrick Breysse and Ely Kovetz

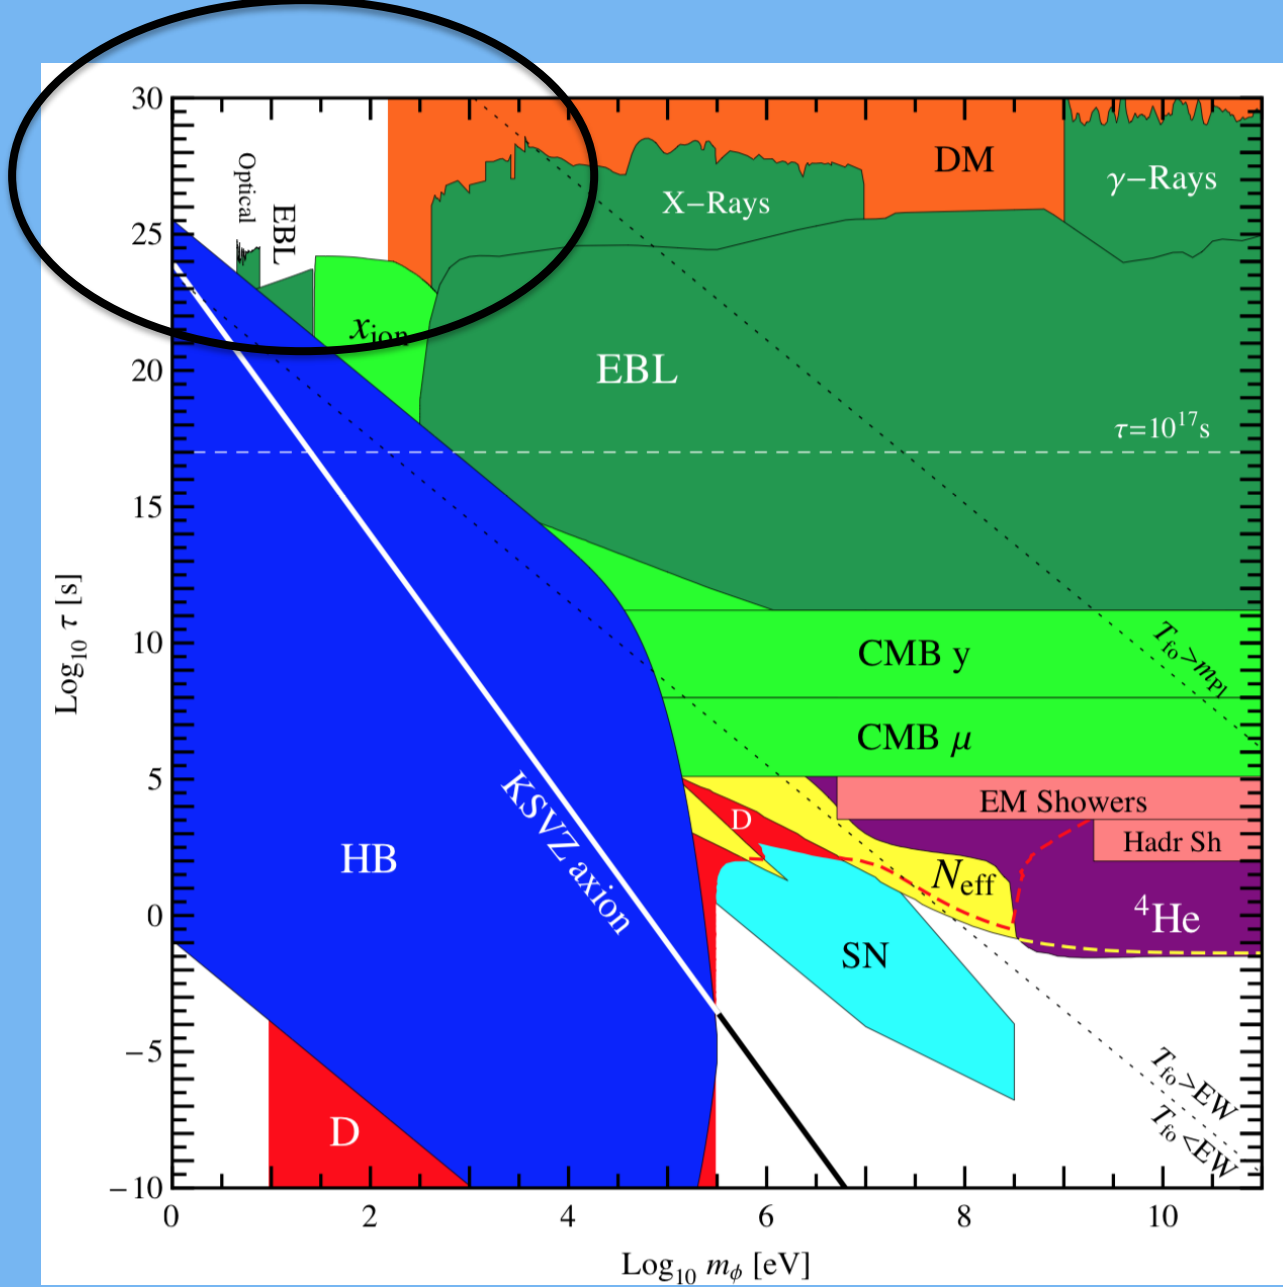

DM decay

- If DM decays to photon line, decay line will be correlated with large-scale structure

Conclusions:

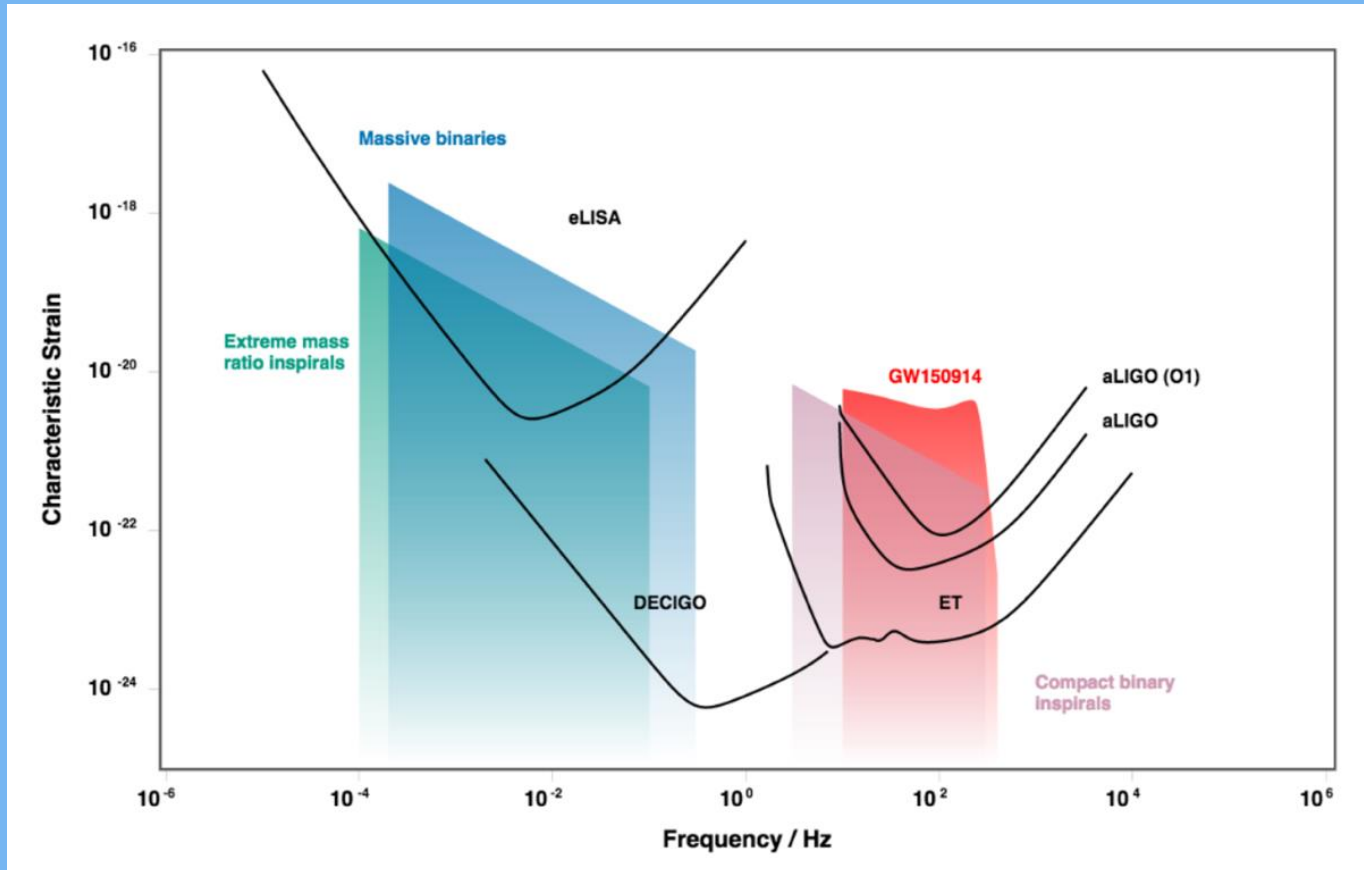

- Parameter space for canonical WIMP shrinking --- time to think anew?
- ~ 30 - M_{sun} PBHs face challenges: now guilty until proven innocent
- EDGES signal is very intriguing, but cooling of hydrogen by scattering from DM hard to come by
- Intensity mapping provides one new astrophysical tool in arsenal of DM seekers
