What can we fit with ~350 TALYS parameters?

# $^{56}\text{Fe}$ differential cross sections (n, ...)

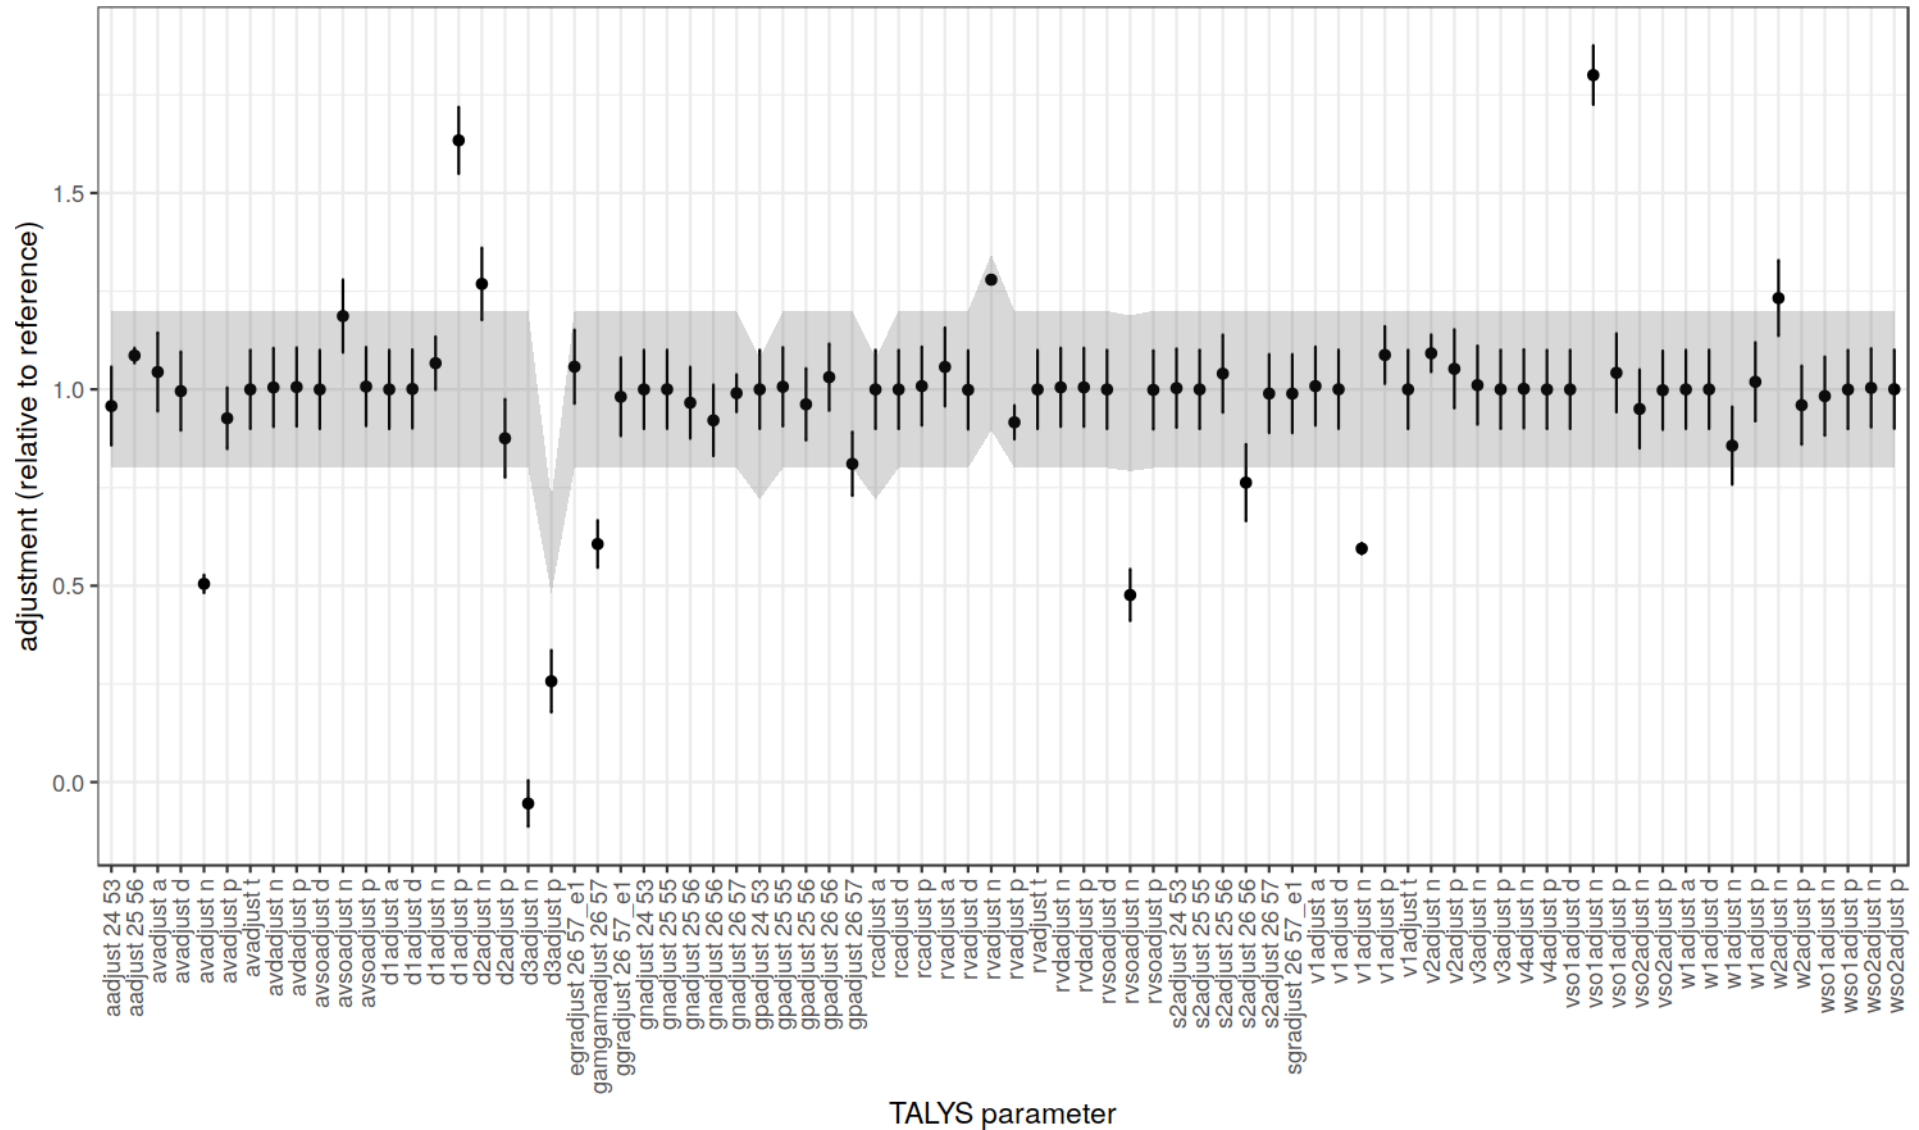

# $^{56}\text{Fe}$ --- update with (n,tot) and (n,p)

(e.g. EMPIRE-Kalman, SAMMY Bayesian update, ...)

# Parameter outlaws

# Evil correlations

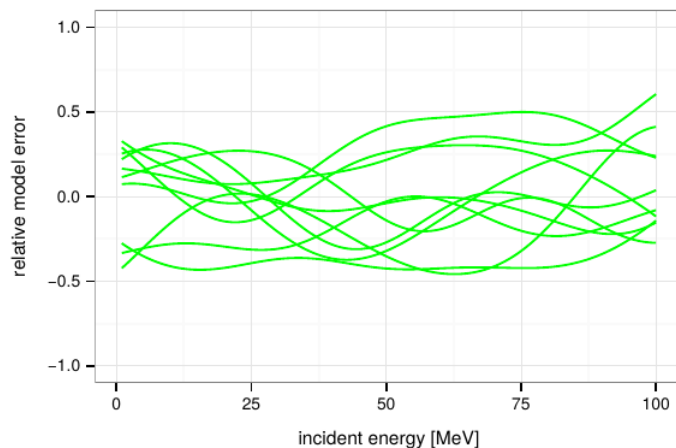

Mike Myers as Dr. Evil in Austin Powers

# Take away

- Reasonable (not too low) uncertainties and parameter estimates of physics models can in general not be obtained by a  $\chi^2$  fit (or GLS, EMPIRE-Kalman, etc. without model defects)
- Otherwise we risk running the model outside sound specifications and losing its predictive power
- We need **model defects**! (Especially if we can fit an elephant or two)

Pigni, M.T., Leeb, H., 2003. Uncertainty Estimates of Evaluated  $^{56}\text{Fe}$  Cross Sections Based on Extensive Modelling at Energies Beyond 20 MeV, in: Proc. Int. Workshop on Nuclear Data for the Transmutation of Nuclear Waste. GSI-Darmstadt, Germany.

# Don't break the law!

$$\chi^2 = (\vec{\sigma}_{\text{exp}} - \mathcal{M}(\vec{p}_{\text{ref}}))^T M^{-1} (\vec{\sigma}_{\text{exp}} - \mathcal{M}(\vec{p}_{\text{ref}}))$$

## Side note

Serves as criterion to remove experimental outliers in TSURFER module of SCALE. Option called  $\Delta\chi^2$ -filtering there

$$M = SK_{\text{par}}S^T + K_{\text{exp}}$$

$$M = SK_{\text{par}}S^T + K_{\text{def}} + K_{\text{exp}}$$

How to choose  $K_{\text{def}}$ ?

if  $K_{\text{def}} \rightarrow \infty$  then  $\chi^2 \rightarrow 0$

$$\pi(\mathcal{D}) = \int \ell(\mathcal{D} | \vec{p}) \pi(\vec{p}) d\vec{p}$$

$$M = SK_{\text{par}}S^T + K_{\text{def}} + K_{\text{exp}}$$

# Marginal likelihood maximization

$$\log \pi(\mathcal{D}) = -\frac{N}{2} \log(2\pi) - \frac{1}{2} \log |M| - \frac{1}{2} \chi^2(M)$$

Brief motivation of criterion

$$M = \begin{pmatrix} \delta^2 & 0 & \dots \\ 0 & \delta^2 & \dots \\ 0 & 0 & \ddots \end{pmatrix} \begin{matrix} \rightarrow -\frac{1}{2} \chi^2(M) = -\frac{1}{2\delta^2} \sum_{i=1}^N (\text{exp}_i - \text{mod}_i)^2 \\ \rightarrow -\frac{1}{2} \log |M| = -\frac{N}{2} \log \delta^2 \end{matrix}$$

$$\mathbb{E} \left[ -\frac{1}{2} \chi^2 M \right] = -\frac{N \delta_{\text{true}}^2}{2\delta^2}$$

$$\delta^2 = \delta_{\text{true}}^2 + \Delta$$

$$\log(\delta_{\text{true}}^2 + \Delta) = \log(\delta_{\text{true}}^2) + \frac{\Delta}{\delta_{\text{true}}^2} - \frac{1}{2} \frac{\Delta^2}{\delta_{\text{true}}^4} + \dots$$

$$\frac{\delta_{\text{true}}^2}{\delta_{\text{true}}^2 + \Delta} = 1 - \frac{\Delta}{\delta_{\text{true}}^2} + \frac{\Delta^2}{\delta_{\text{true}}^4} + \dots$$

$$\log \pi(\mathcal{D}) = \text{const} - \frac{N}{4} \frac{\Delta^2}{\delta_{\text{true}}^4} \rightarrow \text{maximal for } \Delta = 0, \text{ i.e. } \delta^2 = \delta_{\text{true}}^2$$

# New stuff

- Use the data from neighboring isotopes to learn about the apriori performance of the nuclear model on a per energy basis (\*)
- Replace the amplitude and length-scale hyperparameter in the GP by an amplitude function and a metric function

(\*) This point by itself not new, see PhD thesis of Denise Neudecker and [2]

---

Interesting to discuss commonalities and differences but ...

... mind the chairman

## One essential difference:

Here we account for model systematics (in 1<sup>st</sup> order)

$$k(E, E') = \delta^2 \exp\left(-\frac{1}{2} \frac{(E - E')^2}{\lambda^2}\right)$$

# Dynamic time warping GP

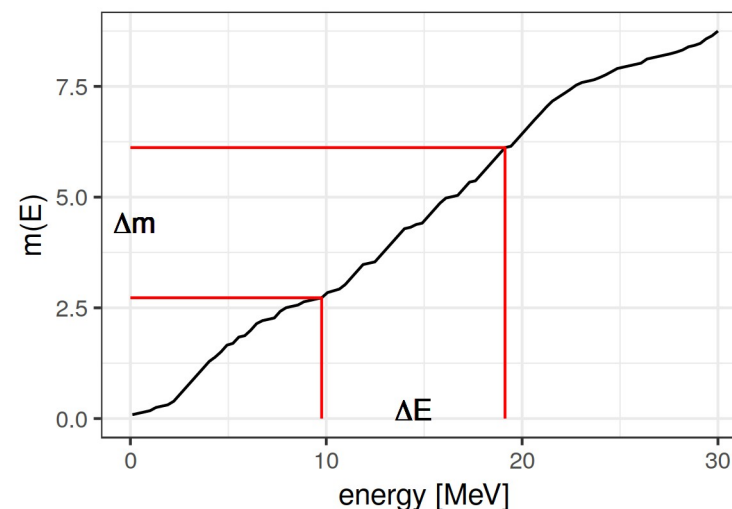

Happy! Got promoted to a function!

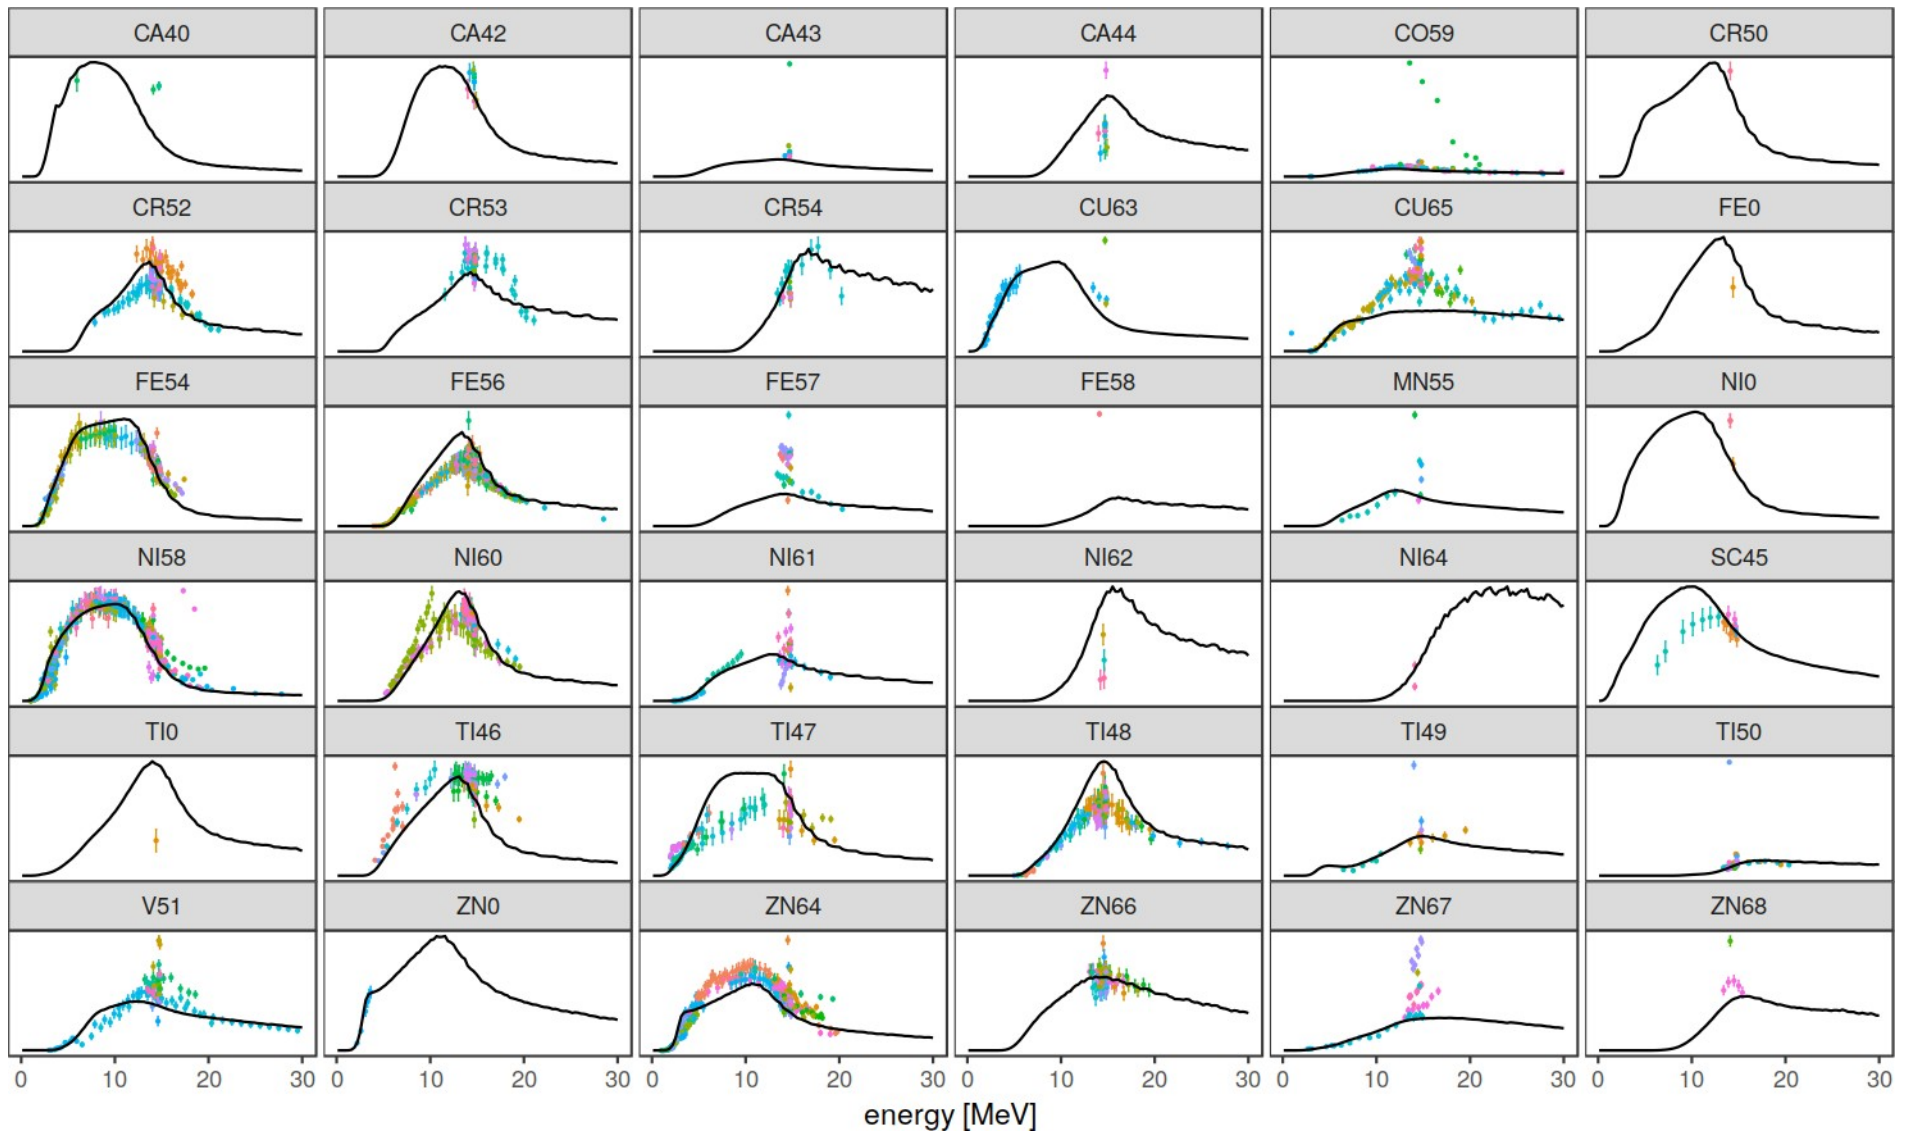

$$k(E, E') = \delta(E)\delta(E') \exp\left(-\frac{1}{2}\left(m(E) - m(E')\right)^2\right)$$

$$\delta(E) = \sum_{i=1}^{99} \left( \frac{E_{i+1} - E}{E_{i+1} - E_i} \mathbf{y}_i + \frac{E - E_i}{E_{i+1} - E_i} \mathbf{y}_{i+1} \right) \mathcal{I}_{(E_i \leq E < E_{i+1})}(E)$$

$$m(E) = \sum_{i=1}^{99} \left( \frac{E_{i+1} - E}{E_{i+1} - E_i} \mathbf{z}_i + \frac{E - E_i}{E_{i+1} - E_i} \mathbf{z}_{i+1} \right) \mathcal{I}_{(E_i \leq E < E_{i+1})}(E)$$

# (n,p) reactions as an example

# Marlike maximization with (n,p) data

[Link to animation \[MP4\]](#)

[Link to animation \[GIF\]](#)

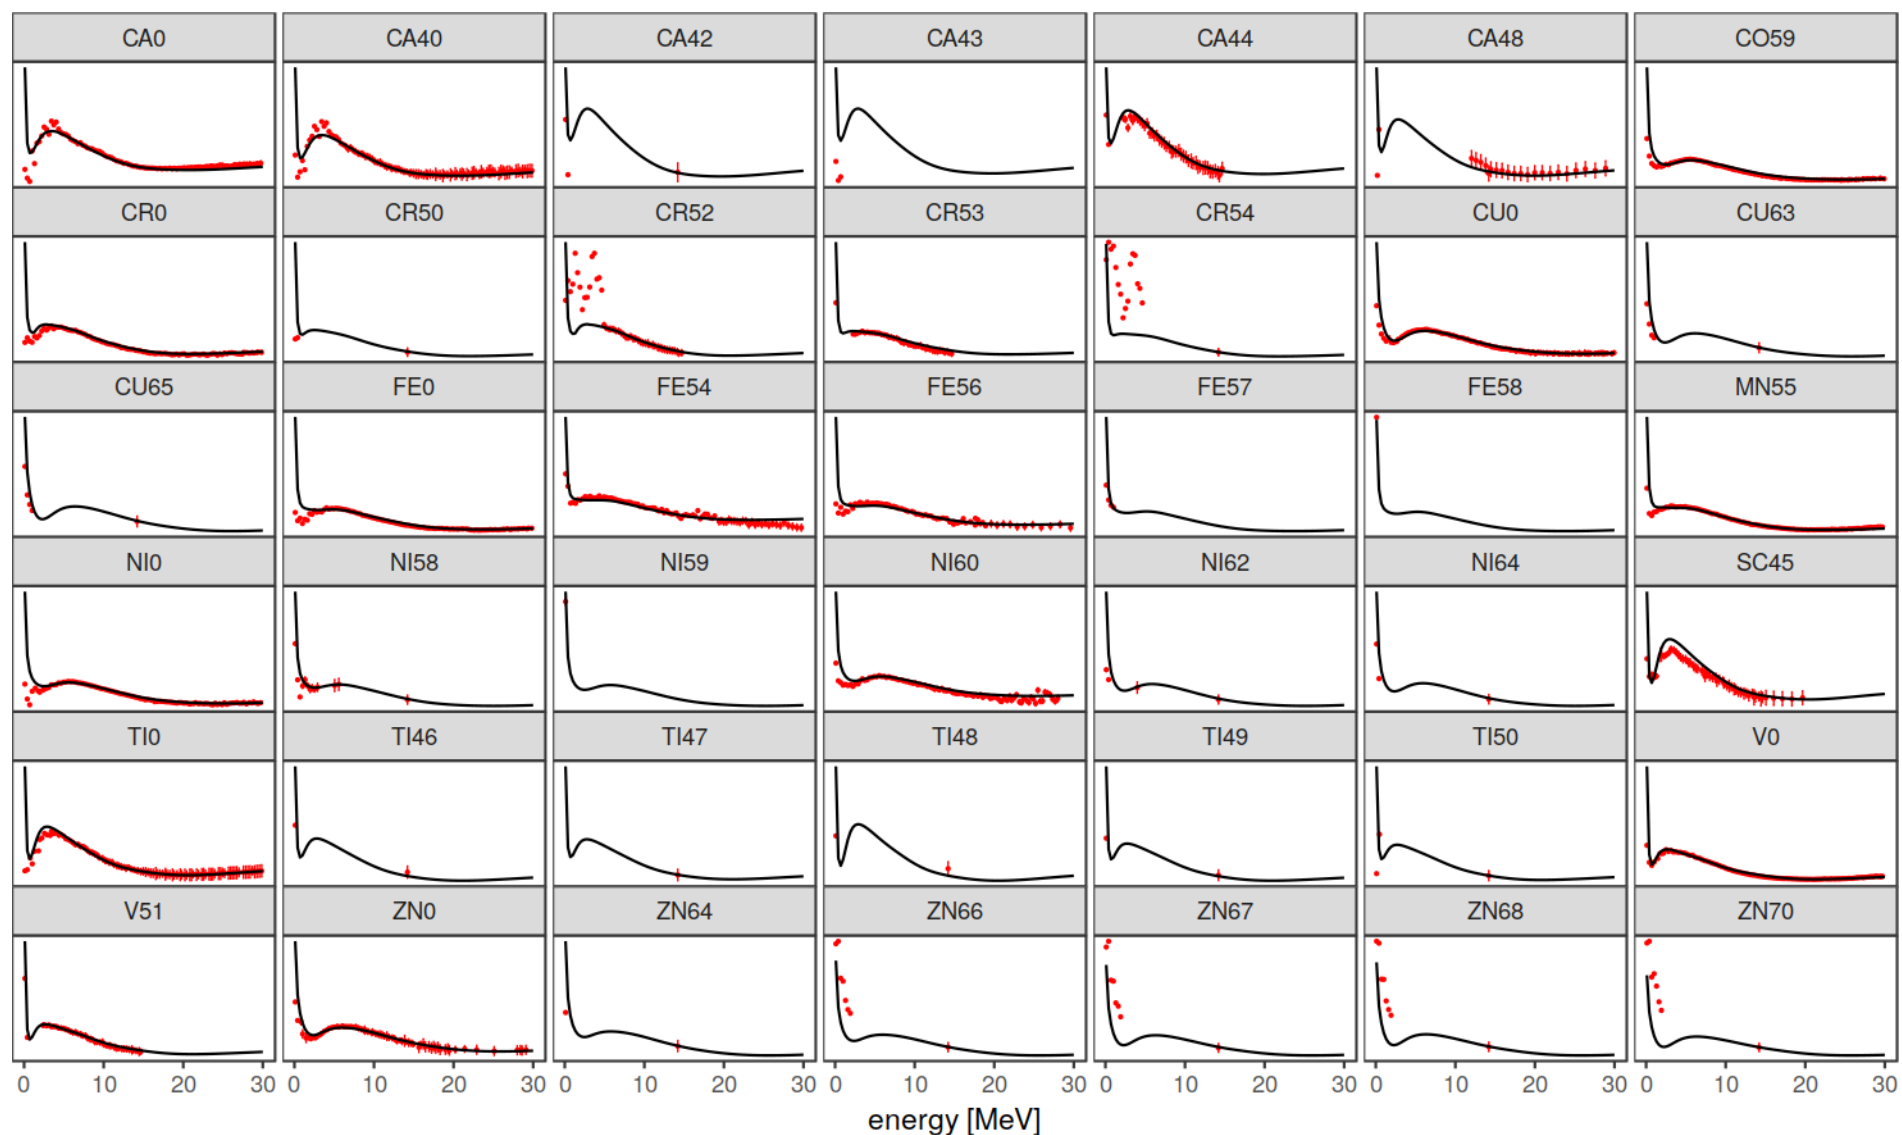

## Remark

Reasonable constraints are important for a successful optimization (e.g., lower bound for length-scale, upper bound for maximal local difference of amplitude, etc.)

# Another example (n,tot)

(0,3 MeV resolution)

# Marlike maxim with (n,tot) data

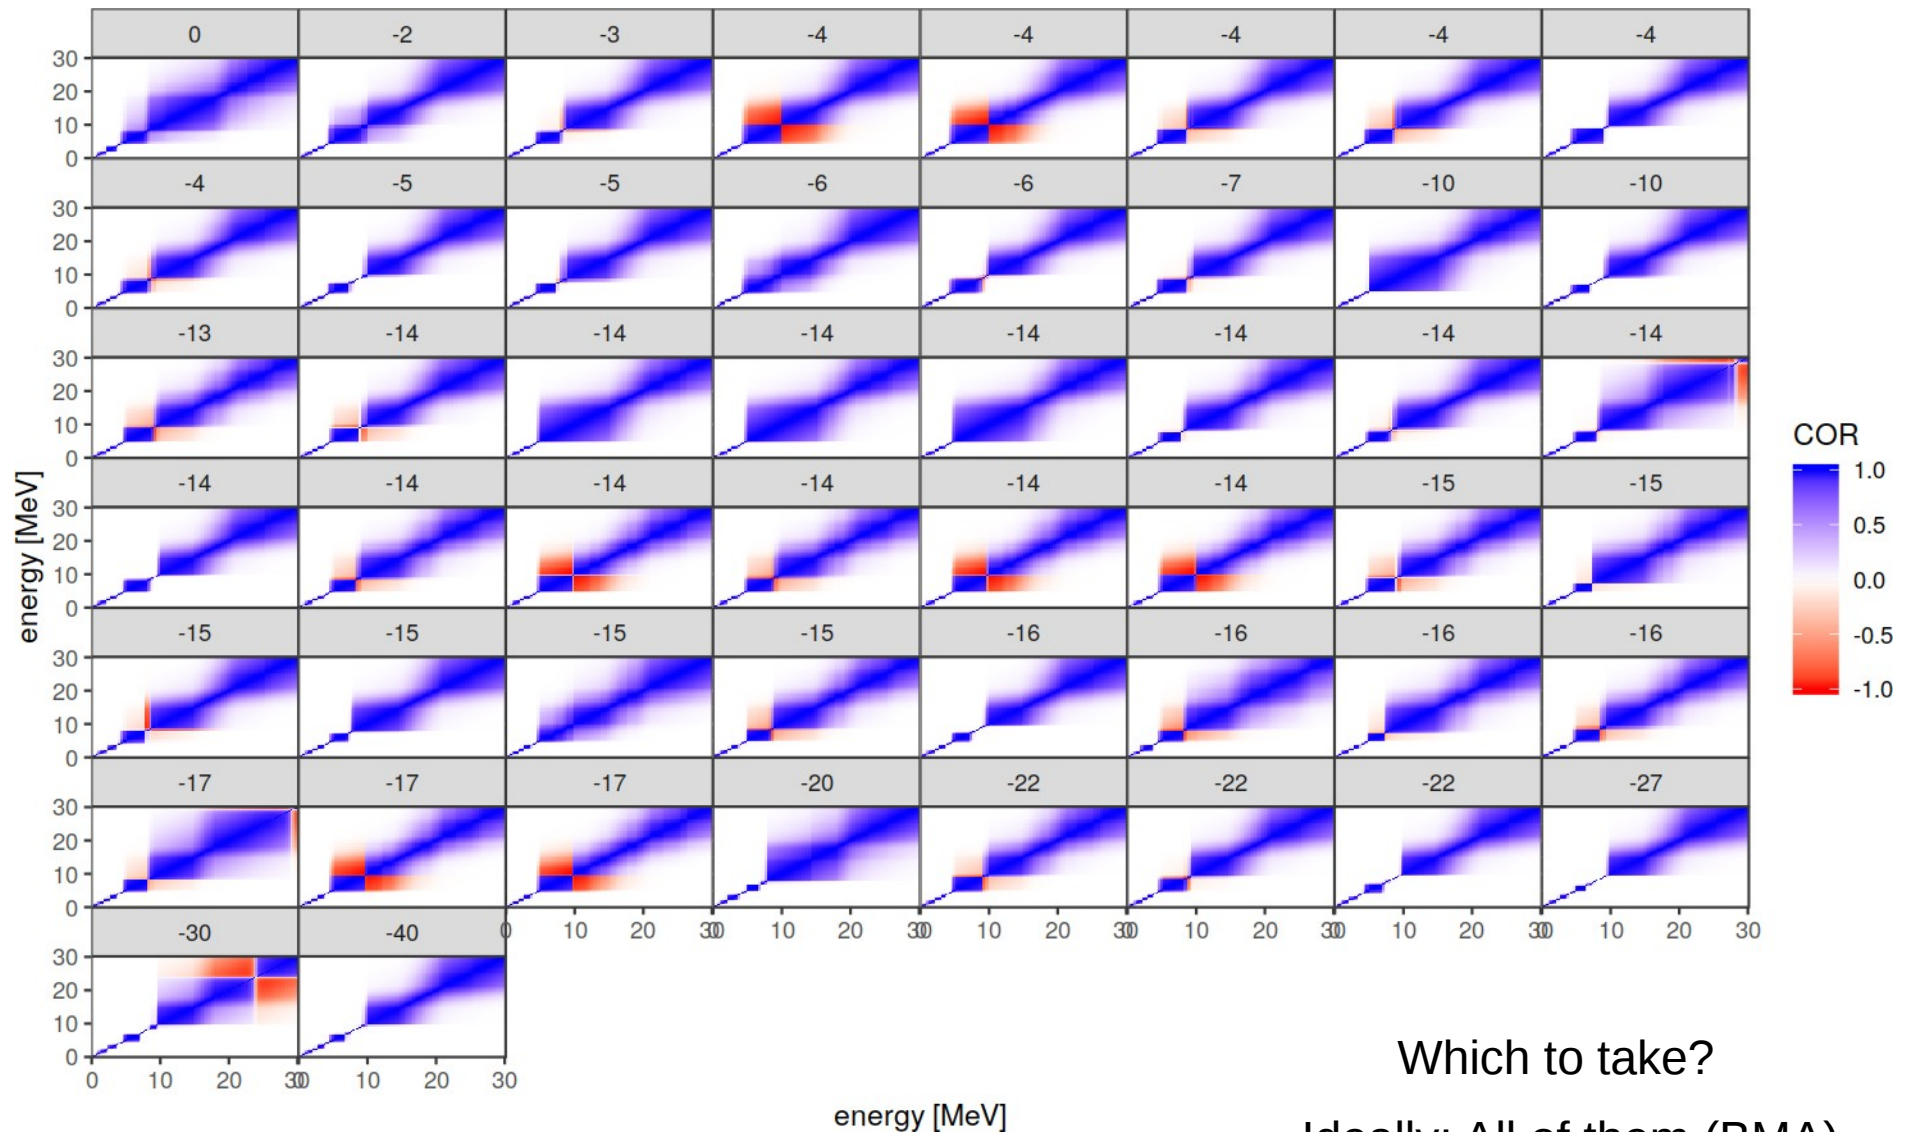

## Remark

Optimization was guided by allowing more flexibility at lower than at higher energies.

# Correlation matrices of defect (n,tot)

# Poor man's BMA

## [again $^{56}\text{Fe}$ update (n,p) and (n,tot)]

# Poor man's BMA

[again  $^{56}\text{Fe}$  update (n,p) and (n,tot)]

# Correlation structure

correlation of defect for (n,tot)

resonance region

[Link to animation \[GIF\]](#)

[Link to animation \[MP4\]](#)

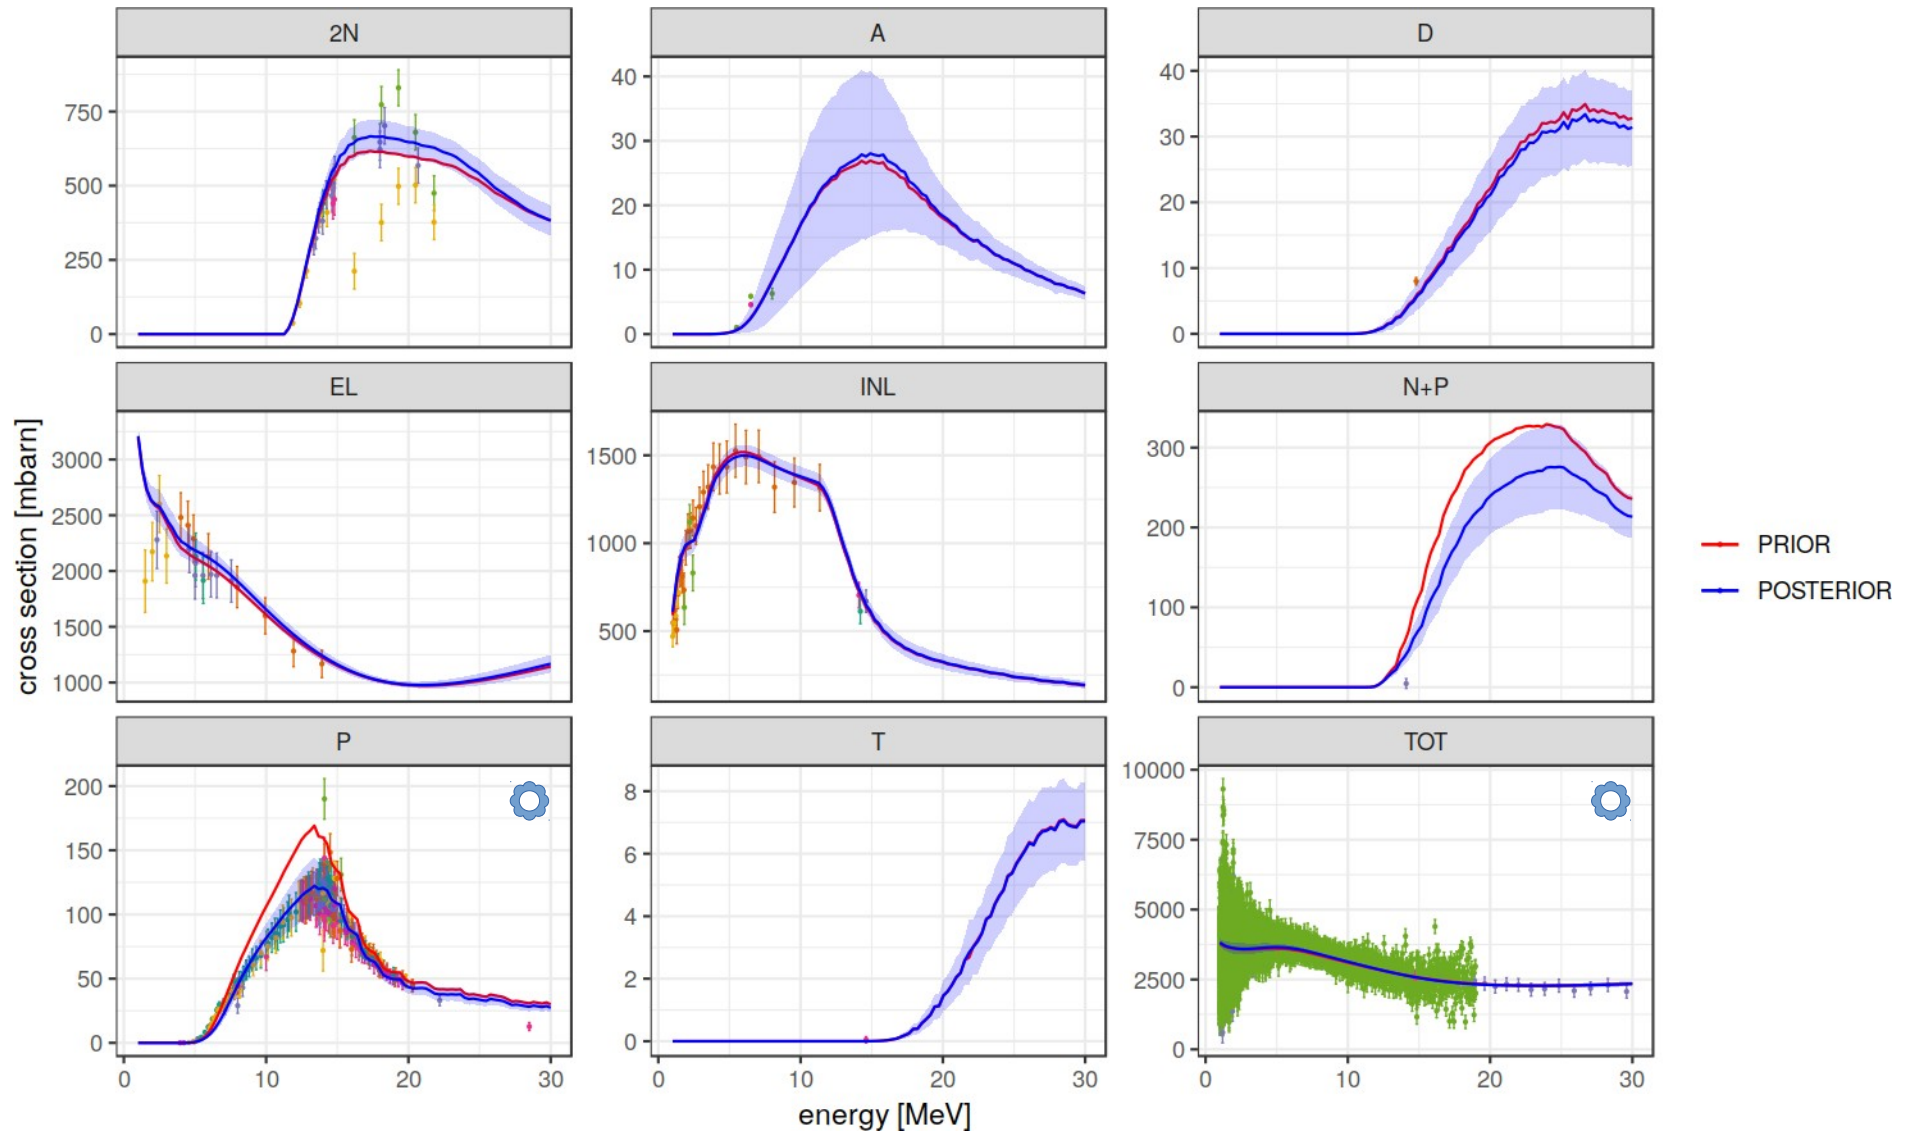

correlation of defect for (n,p)

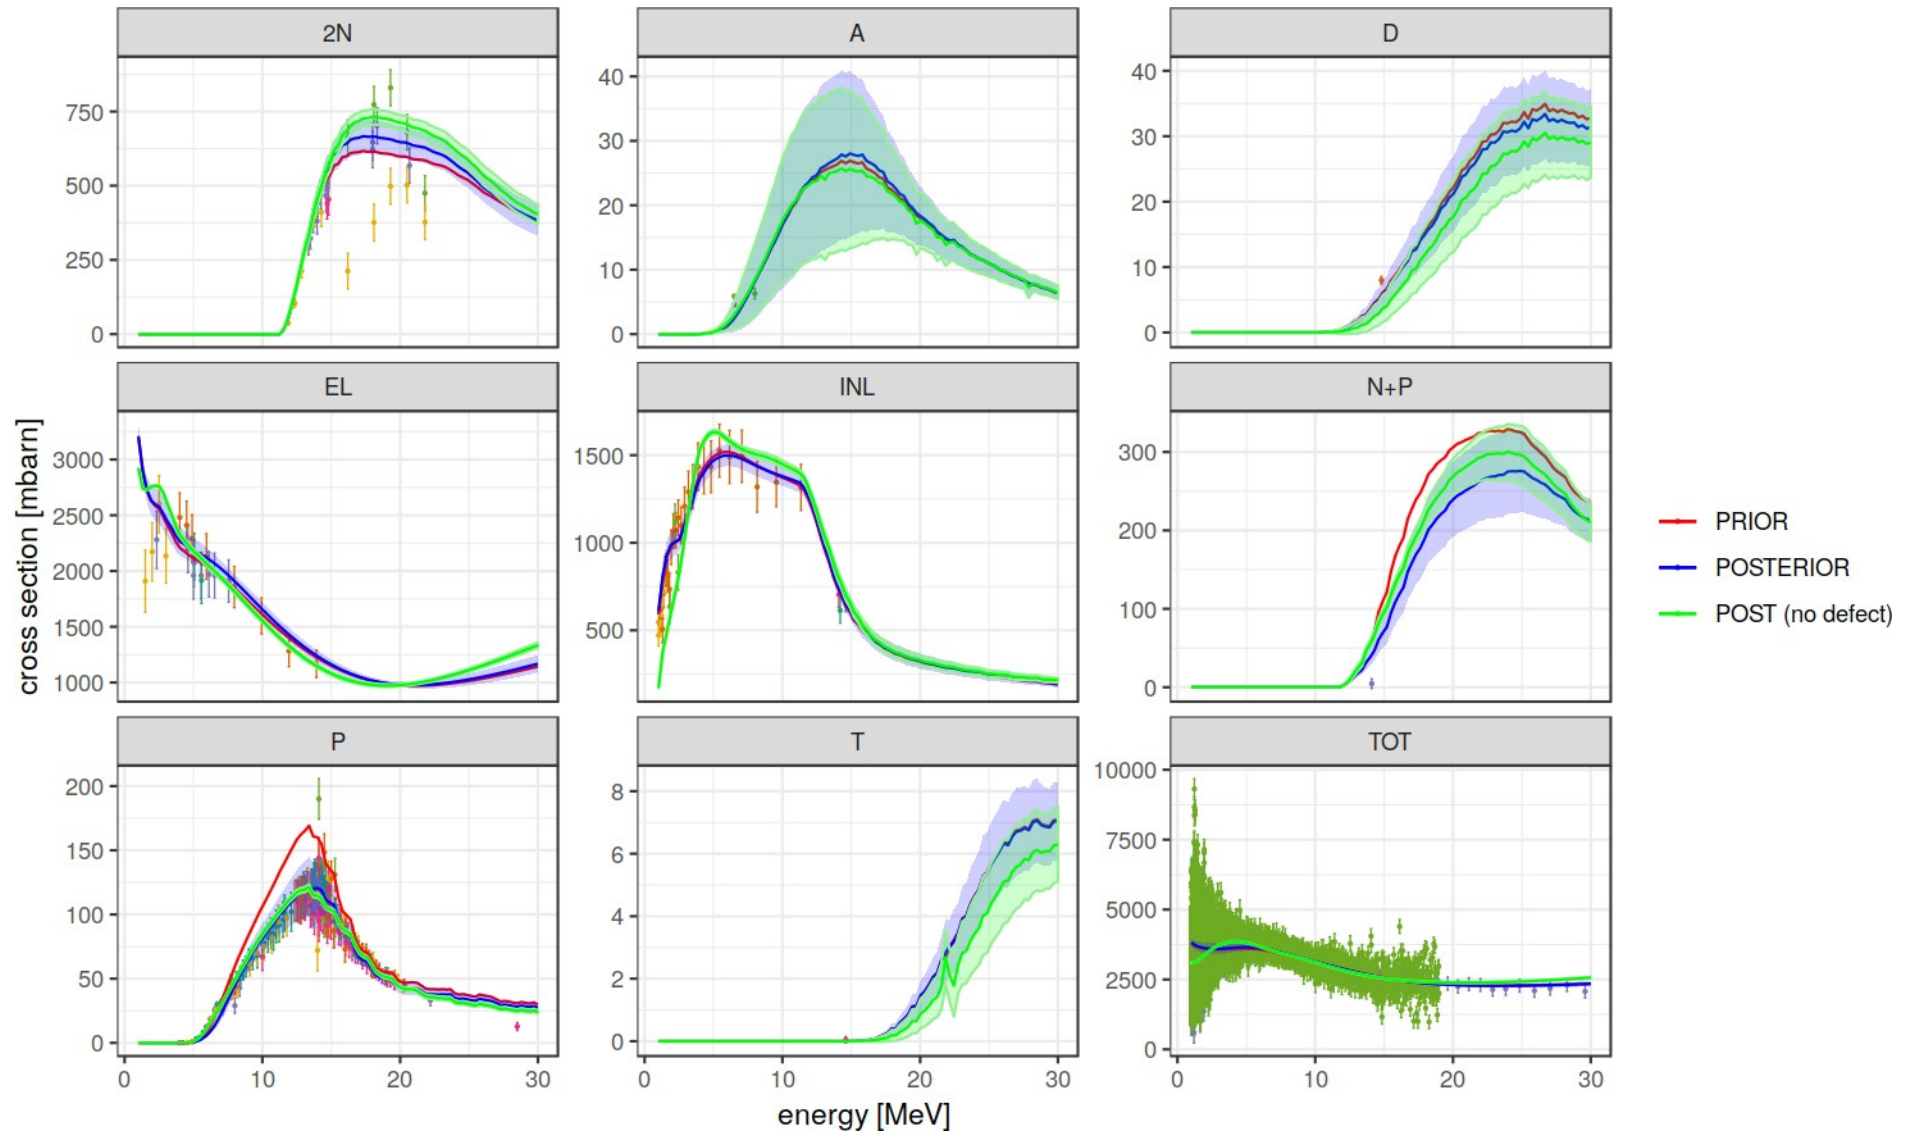

# Updating including defect prior

# Comparison update (def/nodef)

# (Most) Parameters abide by the law

# Updated correlations (with def)

# Summary

- Fitting without using model defects is problematic
- Data-driven approach to learn on a per-energy basis about the performance of the model using a “dynamic time warping GP”
- We can use this information within the Bayesian framework in a principled way to get more reasonable parameter adjustments, uncertainty estimates, etc.
- We can also equip existing methods with this extra information, e.g., GLS, UMC-B, UMC-G, BMC, BFMC, EMPIRE-Kalman, ...
- Of course, a lot of work still ahead (smoothness, BMA, etc.)
- One promising route: Combine it with the idea of energy-dependent TALYS parameters (\*)
