

# Effect of collimator coating thickness on HL-LHC octupole thresholds

---

S. ANTIPOV, N. BIANCACCI

26.02.18

# Motivation and previous work

---

Operation at the HL-LHC intensity ( $2.3 \times 10^{11}$  ppb) is not compatible with the present LHC transverse impedance

In order to reduce the impedance, an upgrade of the collimator system is planned

- Lower the total impedance and the octupole threshold by  $\sim 50\%$

Secondary collimators in IR-7 are coated with  $5 \mu\text{m}$  Mo

- The coating thickness should provide sufficient margins for stable operation

# Goal: Update the estimate on how the thickness of the coating affects the octupole threshold

Most challenging, Ultimate, OP scenario

Three coating scenarios:

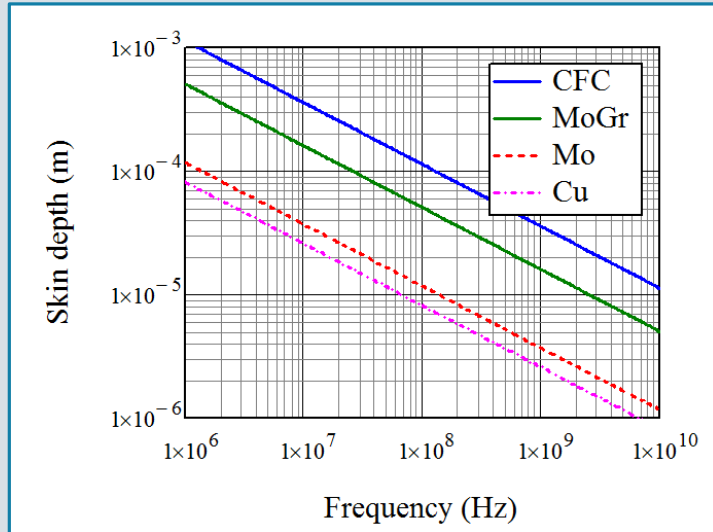

- **Mo+MoGr**
- Cu+MoGr
- Cu+CFC

Various coating thickness:

- 1, 3, **5**  $\mu\text{m}$

| Energy, $\beta^*$              | $E = 7 \text{ TeV}, \beta^* = 40 \text{ cm}$  |
|--------------------------------|---|
| Beam intensity                 | $M = 2760, N_b = 2.3 \times 10^{11} \text{ p}$  |
| Beam emittance<br>Bunch length | $\epsilon_n = 2.1 \mu\text{m}$ (injection)<br>$\sigma_z = 9.0 \text{ cm}$ , rms, Gaussian |
| Damper                         | $d = 100 \text{ turns}^{-1}$  |
| Octupole SD                    | Negative polarity, no ATS<br>Tails cut at 3 rms beam size                                 |
| Collimator settings            | Nominal ( $2.5 \mu\text{m}$ ref. $\epsilon$ ):<br>TCP – $6.7\sigma$<br>TCSG – $9.1\sigma$ |

# The bulk has little effect on impedance for a sufficiently thick coating

| Material | Bulk resistivity (nΩ-m) |
|----------|-------------------------|
| CFC      | 5000                    |
| MoGr     | 1000                    |
| Cu       | 26                      |
| Mo       | 53.5                    |

# Octupole threshold increases for thinner coatings

Mo: +20 A for  $Q' \sim 8-12$

Cu: no significant difference for Cu around  $Q' \sim 10$

The effect may be large at some chromaticities

# Conclusion

---

The choice of bulk collimator material has little effect on the machine impedance and hence beam stability if the coating is sufficiently thick

5  $\mu\text{m}$  coating provides a significant safety margin in terms of the octupole threshold

The increase of octupole current for thinner coatings is relatively small for most positive  $Q'$ , even when its thickness is reduced to 1  $\mu\text{m}$

- Up to 20 A ( $\sim 10\%$  of the total) for Mo coating on MoGr and  $Q' \sim 10$
- Nearly no effect for better coatings with lower resistivity, such as Cu
- The octupole threshold may double for certain values of  $Q'$

# Back-up slides

---

# Impedance of different coating thickness options

# Increase in octupole threshold assuming $\Delta Q' = \pm 1$ uncertainty in $Q'$
