
ITS reconstruction: impact of noise and bad SSD strips

Enrico Fragiaco

INFN Trieste

Offline week, 9-10-2007

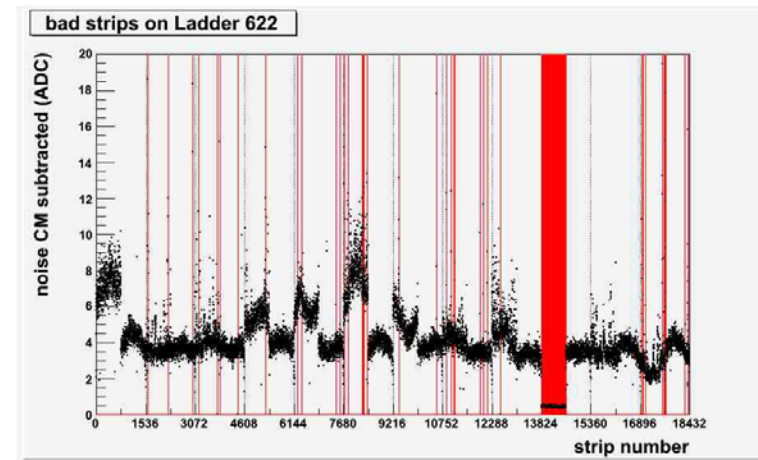

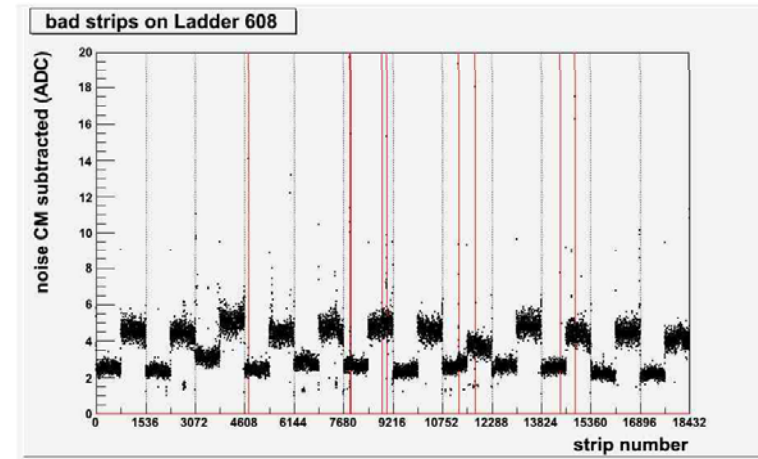

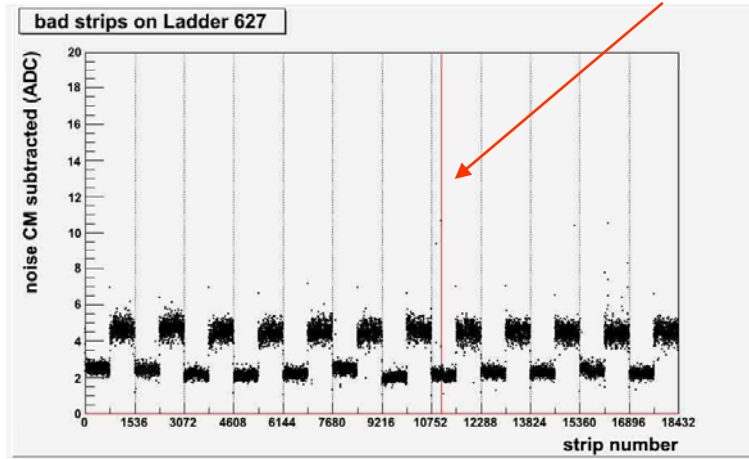

How SSD works

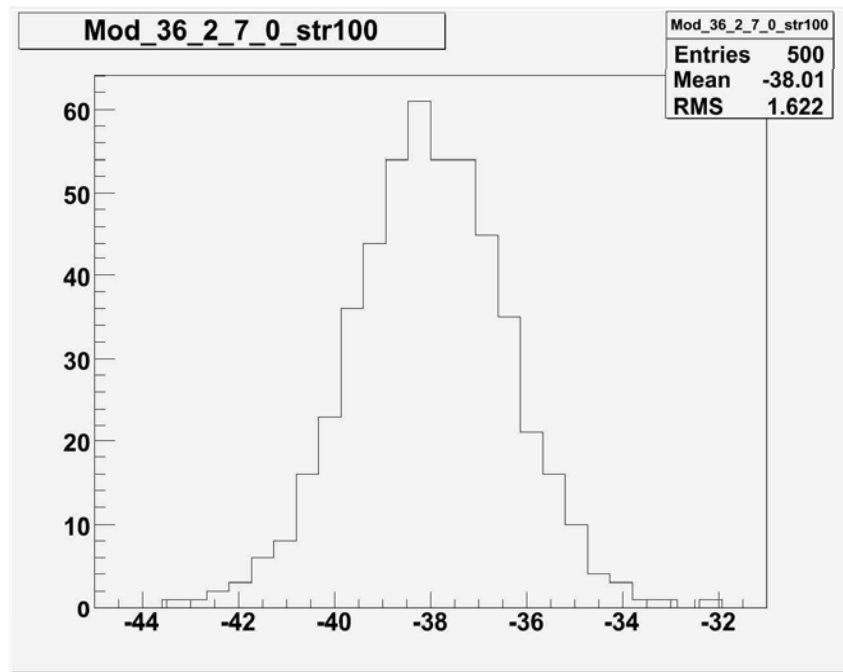

- 748 (lay5) + 950 (lay6) = 1698 double-sided SSD modules
- 768 strips per side
- 35 mrad stereo angle
- Typical charge is 50 (in ADC channels) after pedestal subtraction
- Typical noise is 2 (on Pside) and 4 (on Nside) (in ADC channels)
- Not bad provided noise is gaussian

Noise and bad channels (from tests)

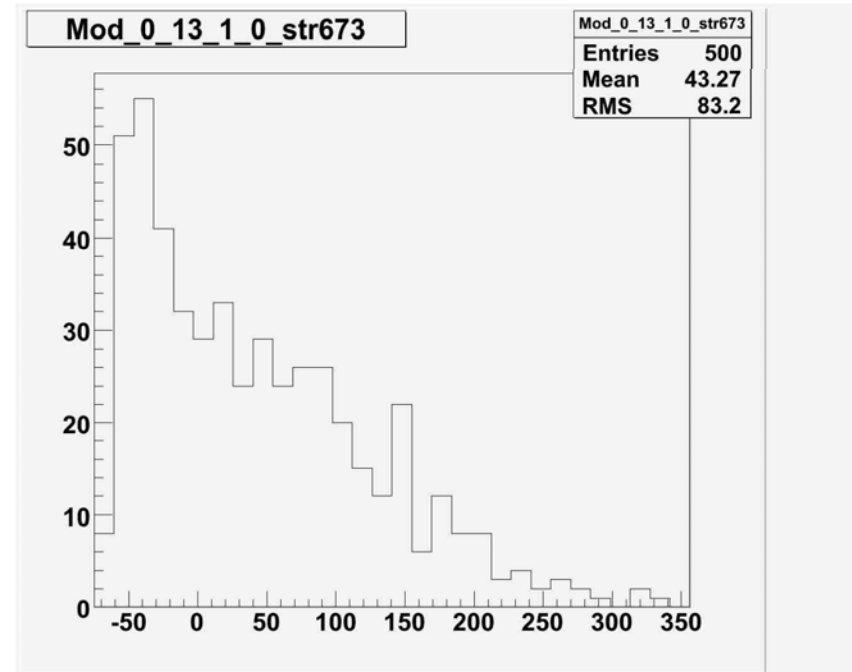

Bad or Dead

Gaussian and non-gaussian behaviours

Noise charge distribution (ADC)

Noise charge distribution (ADC)

Simulated effect of noise and dead channels in the reconstruction

- Simulation of **high-momentum pi+** (3-10 GeV/c) in **$-0.9 < \eta < 0.9$, $0 < \phi < 45$** (corresponds to 1/8 of each SSD layer, ~100 modules per SSD layer)
- Simulation with **1000 and 2000 pi's** (corresponds to 8000 and 16000 in ITS, 40000 and 80000 in ALICE, respectively. Leads to a density of 10 and 20 tracks per SSD module)
- Simulations repeated changing noise values and number of dead strips. Looked at **the tracking efficiencies**

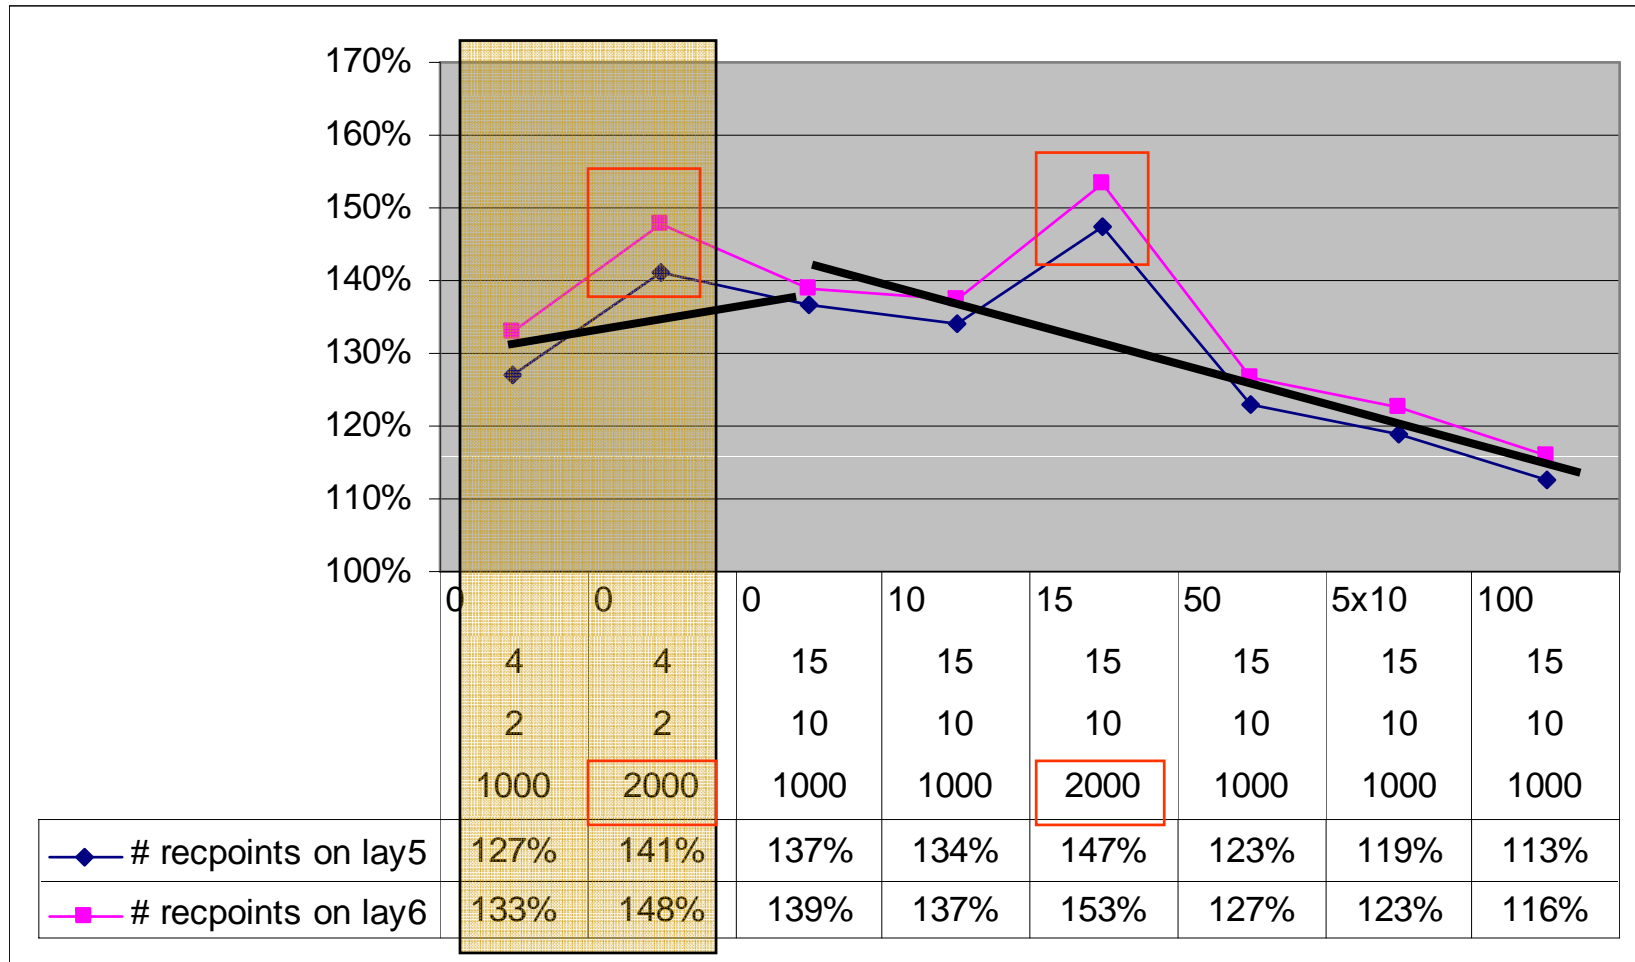

Pions	1000	1000	1000	1000	1000	1000	2000	2000
Pnoise	2	10	10	10	10	10	2	10
Nnoise	4	15	15	15	15	15	4	15
#dead/side	0	0	10	50	5x10	100	0	15

Pions, Pnoise, Nnoise, #dead/side	1000,2,4,0
ESD tracks	1509
Recpoints on Lay5	1270
Recpoints on Lay6	1328
ITSrefit tracks	995 (99.5%)
BadQual/ SSD6used	92/955

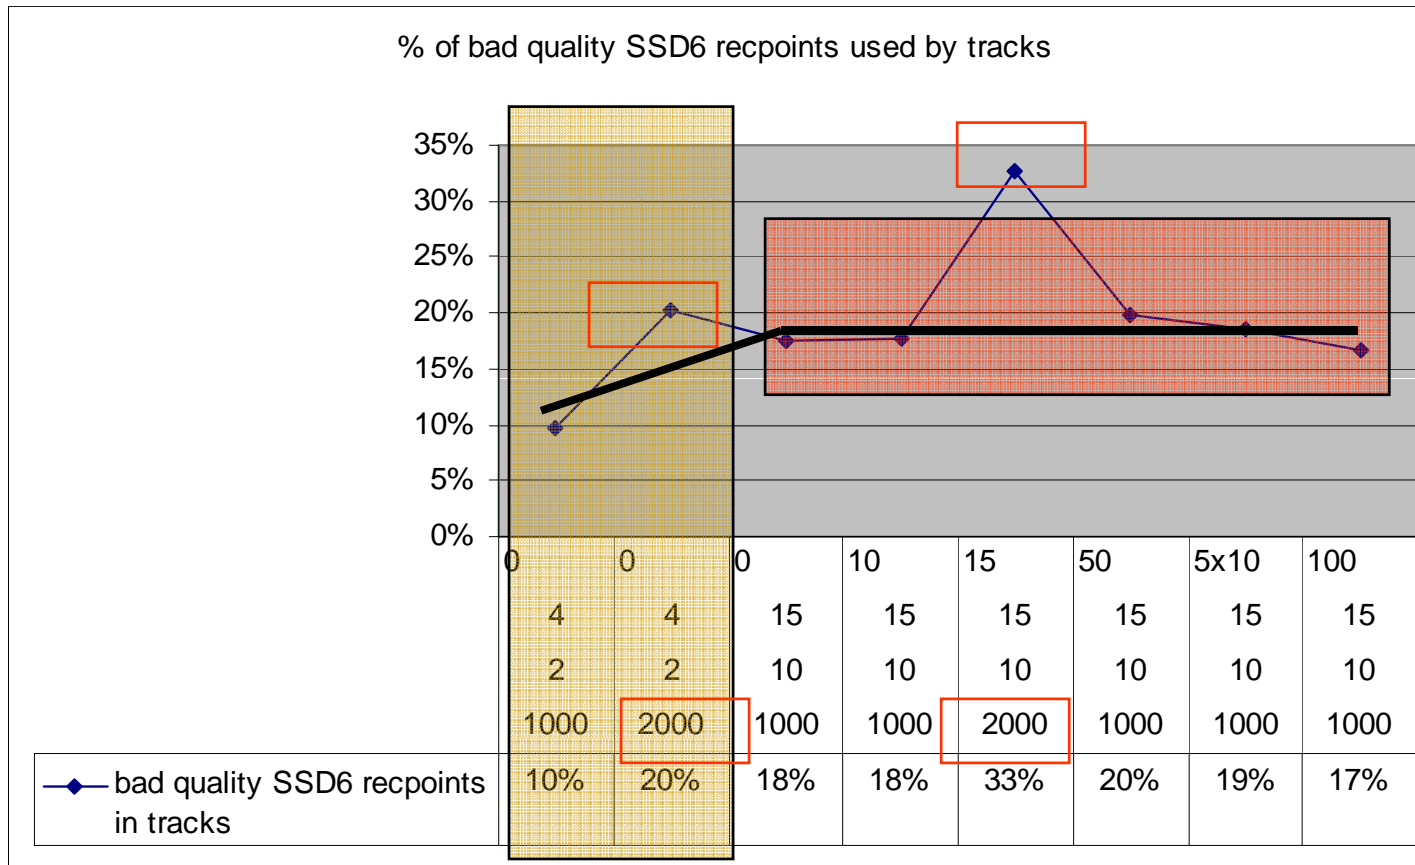

ESD tracks / # primaries pions

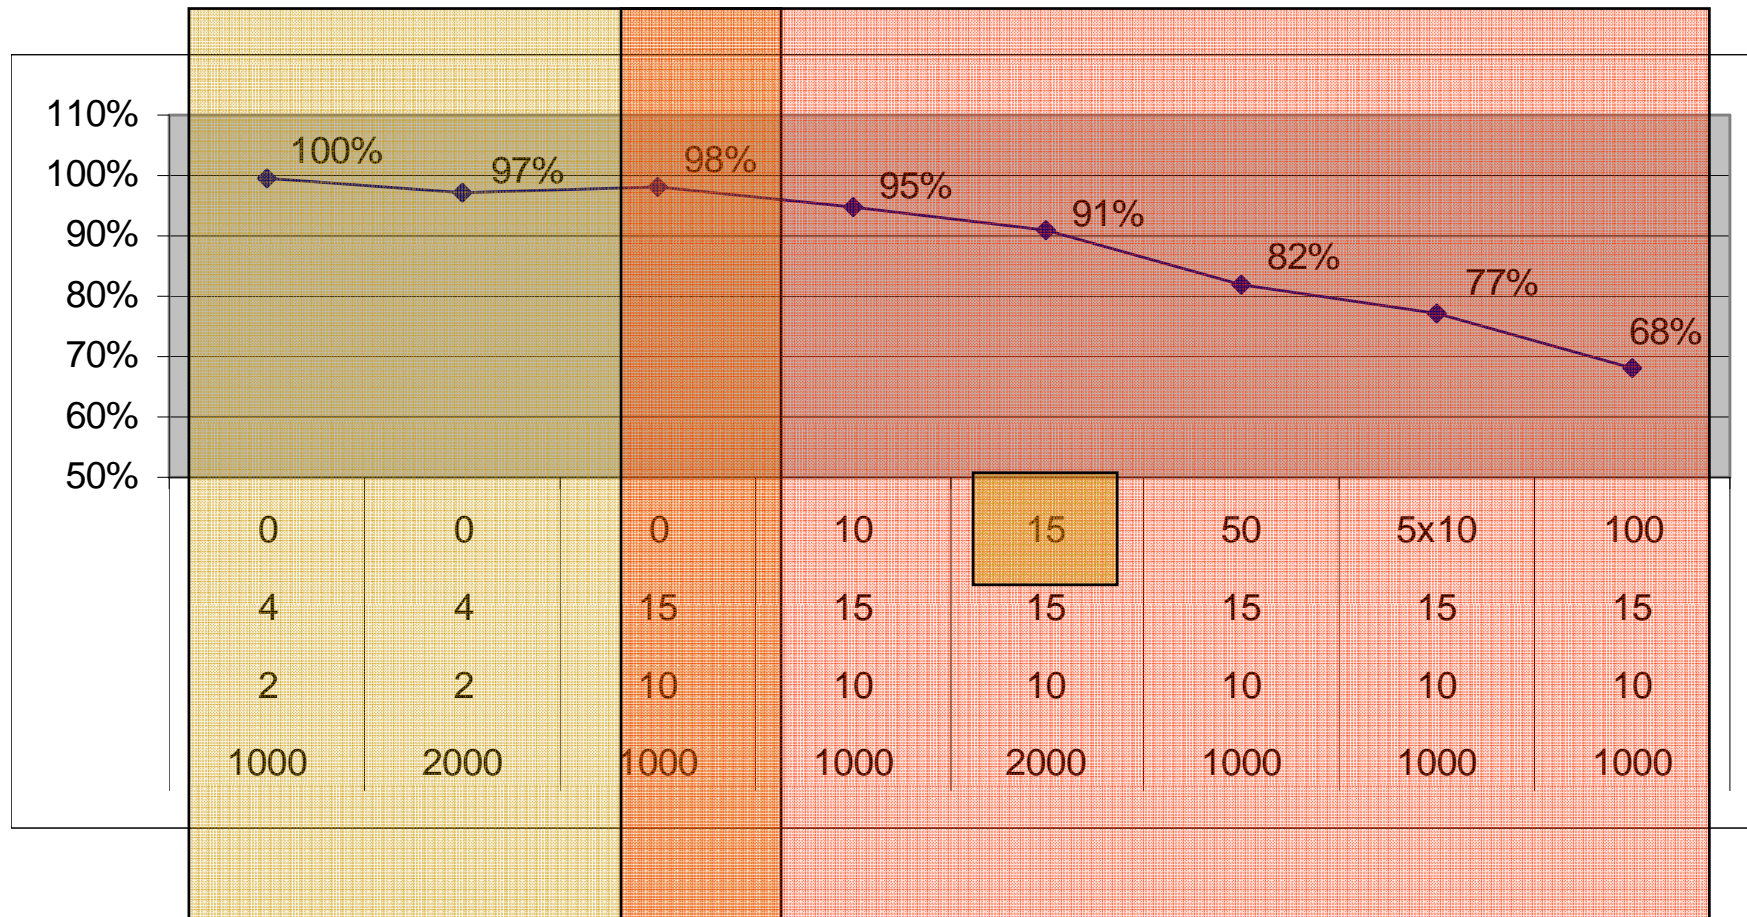

recpoints / # primaries

Bad quality recpoints

ITS-refit tracks / # primaries pions

Conclusions

- Noise mainly affects the quality of recpoints, provided it is gaussian and correctly calculated by the DA (work in progress)
- Noise threshold in the CF will be implemented soon
- Bad (dead+noisy) channels affect reconstruction removing recpoints from the SSD layers (mandatory for ITSrefit!?)
- In the worse case (2%) up to 10% ITSrefit tracks missing
- Calls for algorithms recovering clusters if strips from bad channels map are involved
