

# Technology challenges: Superconducting accelerator magnets PART I/II

**Daniel Schoerling**  
**daniel.schoerling@cern.ch**  
**2<sup>nd</sup> and 3<sup>rd</sup> of July 2018**  
**Summer Student Lecture**

**Thanks to many colleagues, in particular Paolo Ferracin for the material they have given to me**

# Why colliders?

Accelerators are the finest microscopes: *atto-scope or zepto-scope*

$$\lambda = h/p ; \text{ @LHC: } p = 1 \text{ TeV} \Rightarrow \lambda \cong 10^{-18} \text{ m}$$

$\lambda$ : wavelength

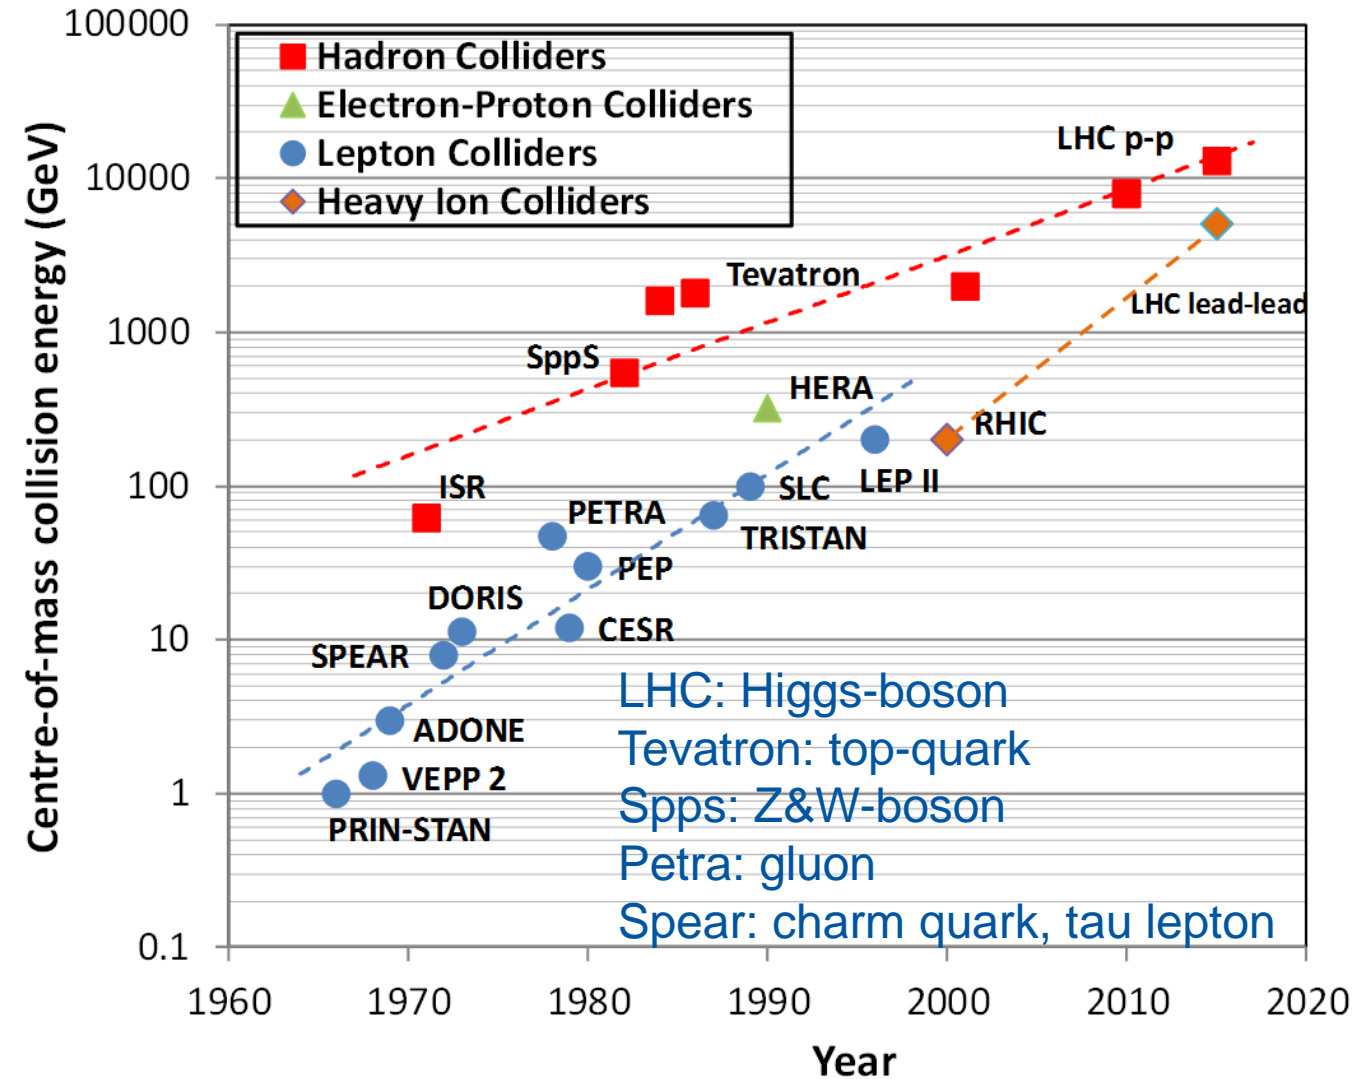

$h$ : Planck constant

$p$ : momentum

# Why SC accelerator magnets and where are they used?

**COLLIDERS** (LEP, Tevatron, Hera, RHIC, LHC, etc.)

- One of the most important parameter of colliders is the beam energy, as it determines the physics discovery potential.

# HÄDRÖNN CJÖLIDDER

CollegeHumor

# Magnets in accelerators, why?

The energy  $E$  in GeV of particles in a circular accelerator is limited by the strength of the bending dipole magnets  $B$  in Tesla and the machine radius  $r$  in m:

$$E \approx 0.3 B r$$

# Dipoles

- The magnetic field  $B$  steers the particles in a circular orbit:  
$$\mathbf{F} = q\mathbf{E} + q\mathbf{v} \times \mathbf{B}$$
- First term ( $q\mathbf{E}$ ) negligible: 300 MV/m corresponds to 1 T

$N/I$ : Ampere turns in A

$J$ : Current density in A/m<sup>2</sup>

$B$ : Magnetic flux density in T = N/Am

$v$ : velocity in m/s

$F$ : Force in N

$\rho$ : particle path radius in m

# Why SC magnets?

## Normal-conducting iron-dominated magnets:

- $B \approx \mu_0 NI / g$
- Limited by the iron saturation:  $B \lesssim 2 \text{ T}$
- Ohmic losses, cooling, power converters, etc.
  
- $g = 100 \text{ mm}$  (gap)
- $NI = 160 \text{ kA}$  (Ampere turns)
- **$B = 2 \text{ T}$  (Magnetic flux density, limit)**

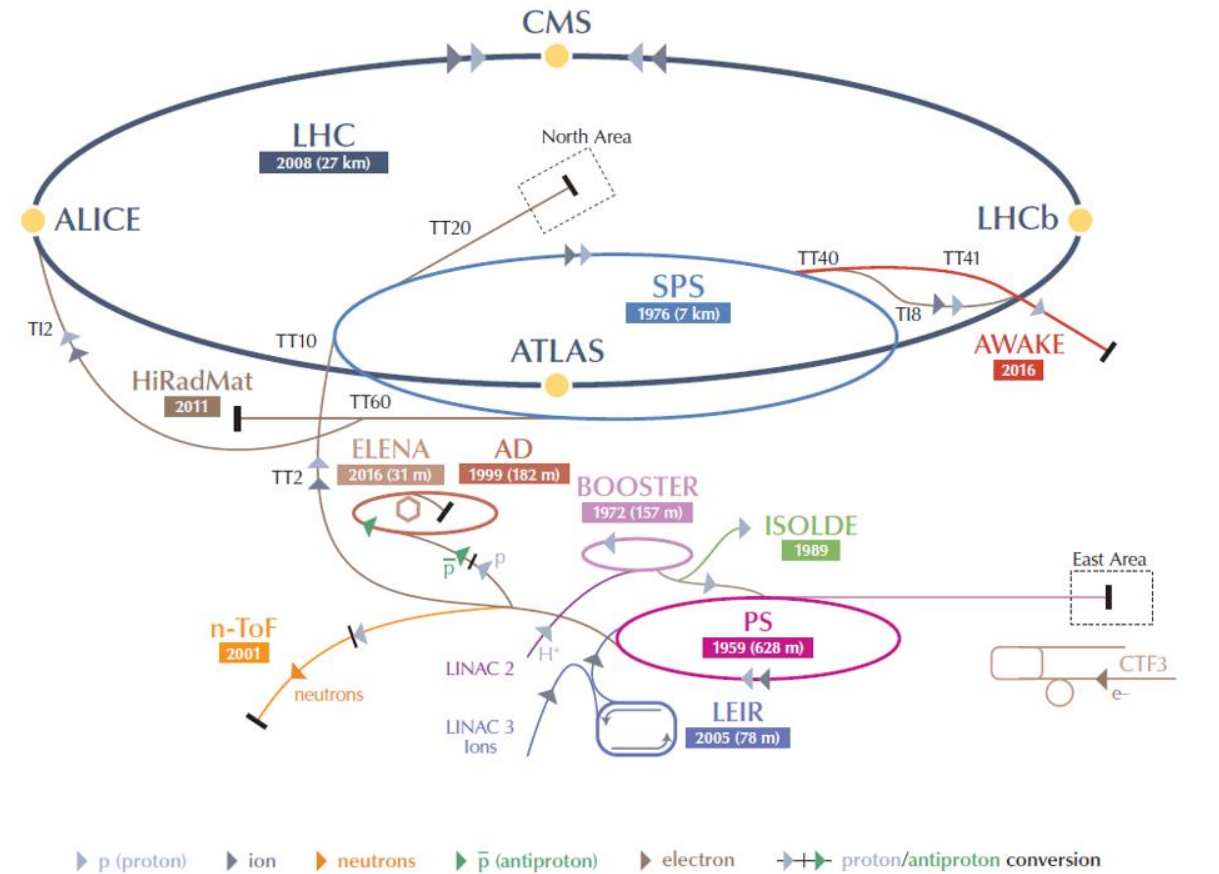

## Superconducting magnets:

- $B \approx \mu_0 NI / \pi r$
- Limited only by SC material properties and cost
- Cooling, power converters, busbars
  
- $r = 1/2g = 45 \text{ mm}$  (aperture radius)
- $NI = 1 \text{ MA}$  (Ampere turns)
- **$B = 8.84 \text{ T}$  (magnetic flux density)**

# In which domains do we need to work?

Multidisciplinary field:

- Chemistry and material science: superconducting materials
- Quantum physics: the key mechanisms of superconductivity
- Classical electrodynamics: magnet design
- Mechanical engineering: support structures
- Electrical engineering: powering of the magnets
- Cryogenics: keep them cool ...
- Industrialization & large and complex project management
- Cost modelling
- Impact on society

Very different fields and multi-disciplinary field not limited to physics and engineering

# What do we need to do to get a good design?

Let's focus on the main (technical) points:

- Conductor and cable design, which superconducting material, strand and cable to choose?
- How to do the electromagnetic and structural design of the coil (field and field quality load line margin, quench)?

**AIM OF LECTURE: Understand the main technical concepts relevant in superconducting accelerator magnets!**

Superconducting material

Superconducting strand

Superconducting cable

Superconducting coil

Superconducting magnet

# Part I/II

---

## Part I

- Superconductivity
- Electromagnetic coil design
- Coil manufacture

## Part II

- Margins and quench protection
- Structural design and assembly
- Testing
- Outlook, what brings the future?

# Superconducting material

- Superconductivity discovered in 1911 by Kammerlingh-Onnes: ZERO resistance of mercury wire at 4.2 K
- Temperature at which the transition takes place: critical temperature  $T_c$
- Observed in many materials: but not in the typical best conductors (Cu, Ag, Au)

**Kammerlingh-Onnes proposed 1913 a 10 T solenoid, but it took 50 years (!) of hard work to make this dream come true**

# Superconductivity – Type I superconductors

Meissner-Ochsenfeld effect (1933):

- Perfect diamagnetism: With  $T < T_c$  magnetic field is expelled
- No magnetic field inside the superconductor → no transport current inside a round conductor

Material	$T_c$ (K)	$\mu_0 H_0$ (mT)
Aluminum	1.2	9.9
Cadmium	0.52	3.0
Gallium	1.1	5.1
Indium	3.4	27.6
Iridium	0.11	1.6
Lanthanum $\alpha$	4.8	
$\beta$	4.9	
Lead	7.2	80.3
Lutecium	0.1	35.0
Mercury $\alpha$	4.2	41.3
$\beta$	4.0	34.0
Molybdenum	0.9	
Osmium	0.7	~ 6.3
Rhenium	1.7	20.1
Rhodium	0.0003	4.9
Ruthenium	0.5	6.6
Tantalum	4.5	83.0
Thalium	2.4	17.1
Thorium	1.4	16.2
Tin	3.7	30.6
Titanium	0.4	
Tungsten	0.016	0.12
Uranium $\alpha$	0.6	
$\beta$	1.8	
Zinc	0.9	5.3
Zirconium	0.8	4.7

# Superconductivity – Type I superconductors

Question: Which experiment demonstrates the Meisner-Ochsenfeld effect?

Rope  
Permeant  
magnet

Pb,  $T < 7.2 \text{ K}$

$T < 7.2 \text{ K}$

-Temperature is kept constant  
-Magnet does not fall down after releasing the rope

$T < 7.2 \text{ K}$

$T > 7.2 \text{ K}$

-Cool down  
-Magnet starts hoovering

$T < 7.2 \text{ K}$

# Superconductivity – Type I superconductors

Rope  
Permanent magnet  
Pb,  $T < 7.2\text{ K}$

Eddy currents are generated. No resistance is present in the superconductor. Therefore, the small permanent magnet hovers.

# Superconductivity – Type I superconductors

Rope  
Permanent  
magnet  
Pb,  $T < 7.2\text{ K}$

Perfect diamagnetism: Meissner-Ochsenfeld effect. Magnetic field lines are expelled from the Type I superconductor. As a result the magnet starts hovering.

# Superconductivity – Type II superconductors

- So, for 40-50 years, superconductivity was a research activity
- Then, in the 50's, type II superconductors were discovered:
  - Between  $B_{c1}$  and  $B_{c2}$ : mixed phase
  - $B$  penetrates as flux tubes: fluxoids with a flux of  $\phi_0 = h/2e = 2 \cdot 10^{-15}$  Wb
- Much higher fields and link between  $T_c$  and  $B_{c2}$

# Superconductivity – Hard superconductors

- ...but, if a current passes through the tubes
  - Lorentz force on the fluxoids:  $f = J \times B$
- The force causes a motion of tubes
  - Flux motion ( $dB/dt$ )  $\rightarrow$  ( $V$ )  $\rightarrow$  dissipation ( $VI$ )
- Fluxoids must be locked by pinning centres
  - Defects or impurities in the structure

- The pinning centres exert a pinning force as long as  $f \leq J \times B$ :
- No flux motions  $\rightarrow$  no dissipation
- $J_c$  is the current density at which, for a given  $B$  and at a given  $T$  the pinning force is exceeded by the Lorentz force

Buckel and Kleiner: Superconductivity

# Superconductivity – Critical surface

A type II material is superconductor below the critical surface defined by

- Critical temperature  $T_c$  (property of the material )
- Upper critical field  $B_{c2}$  (property of the material)
- Critical current density  $J_c$  (property of the material but in practice hard work by the producer)

# Technical superconductors: Nb-Ti (1961) and Nb<sub>3</sub>Sn (1954)

- Nb and Ti: ductile alloy
  - Production route: Extrusion + drawing
  - $T_c$  is ~9.2 K at 0 T
  - $B_{c2}$  is ~14.5 T at 0 K
  - Firstly in Tevatron (80s), then in HERA, RHIC and LHC
  - ~50-200 US\$ per kg of wire (1 euro per m)
- Nb and Sn → intermetallic compound
  - Brittle, strain sensitive, formed at ~650-700°C
  - $T_c$  is ~18 K at 0 T
  - $B_{c2}$  is ~28 T at 0 K
  - Used in NMR, ITER, HL-LHC and baseline for FCC
  - ~700-1500 US\$ per kg of wire (target price for FCC: 500 US\$ per kg of wire)

# Conductors: from Cu to Nb<sub>3</sub>Sn

0.85 mm diameter strand

Cu

$$J_e \sim 5 \text{ A/mm}^2$$

$$I \sim 3 \text{ A}$$

$$B = 2 \text{ T}$$

Nb-Ti

$$J_e \sim 600\text{-}700 \text{ A/mm}^2$$

$$I \sim 300\text{-}400 \text{ A}$$

$$B = 8\text{-}9 \text{ T}$$

Nb<sub>3</sub>Sn

$$J_e \sim 600\text{-}700 \text{ A/mm}^2$$

$$I \sim 300\text{-}400 \text{ A}$$

$$B = 12\text{-}16 \text{ T}$$

$$I \sim 300\text{-}400 \text{ A}$$

$$B = 12\text{-}16 \text{ T}$$

# Why small filaments? Stability!

- Simple model: SC carries either  $J_c$  or no current  $\rightarrow$  If field is changed, eddy currents are resistively damped
- The conductor is stable as long as temperature stays below the critical temperature  $T_c$

One large filament	Several ( $N \gg 1$ ) small filaments
same SC area, i.e. $a_L^2 = Na_s^2$	
total volumetric heat [J/m <sup>3</sup> ]	
$Q_L \approx \frac{8\Delta B}{3\pi} J_c a_L$	$Q_S \approx \frac{8\Delta B}{3\pi} J_c a_s$

$$\frac{Q_S}{Q_L} = \frac{a_s}{a_L} = \frac{a_s}{a_s \sqrt{N}} \text{ for } N = 100 \quad \frac{Q_S}{Q_L} = \frac{1}{10}$$

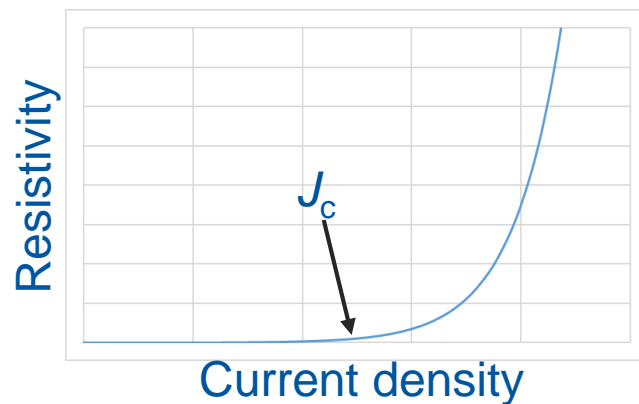

$$a \leq \sqrt{\frac{3\gamma C(\theta_c - \theta_0)}{\mu_0 j_c^2}}$$

# Why Cu? Stability & Protection!

## Quench protection

- Superconductors have a very high normal state resistivity
- If quenched, could reach very high temperatures in few ms
- If embedded in a high-purity copper matrix, when a quench occurs, current redistributes in the low-resistivity matrix yielding to a lower peak temperature

# Stability?

Question: What is the cause of the instabilities seen in the plot below for field levels below ~10 T?

Critical current of a  $\text{Nb}_3\text{Sn}$  wire vs. magnetic field (measured)

# What about AC losses? Twisting!

## Twisting

- When a multi-filamentary wire is subjected to a time varying magnetic field, current loops are generated between filaments.
- If filaments are straight, large loops with large currents  $\rightarrow$  AC losses
- If the strands are magnetically coupled the effective filament size is larger  $\rightarrow$  flux jumps

To reduce these effects, filaments are twisted, the twist pitch is of the order of 20-30 times of the wire diameter.

by M. Wilson

# And magnetization

## Superconductor magnetization

- A hard superconducting filament shows a magnetization curve, as the one shown on the right
- The magnetization stays constant (if no flux jumps occur) at constant field: persistent current
- Field persistent currents produce field errors proportional to  $J_c a$ 
  - HERA filament diameter 14  $\mu\text{m}$
  - LHC filament diameter 6-7  $\mu\text{m}$
  - HL-LHC filament diameter 50  $\mu\text{m}$
  - FCC target filament diameter 20  $\mu\text{m}$

# Practical superconductors: Fabrication of Nb-Ti multifilament wires

- Nb-Ti ingots
- 200 mm  $\varnothing$ , 750 mm long
- Monofilament rods are stacked to form a multifilament billet, then extruded and drawn down
- Can be re-stacked: double-stacking process

# Practical superconductors: Fabrication of Nb<sub>3</sub>Sn multifilament wires

- Since Nb<sub>3</sub>Sn is brittle it cannot be extruded and drawn like Nb-Ti.
- Process in several steps
  - Assembly multifilament billets from with Nb and Sn separated
  - Fabrication of the wire through extrusion-drawing
  - Fabrication of the cable
  - Fabrication of the coil
- Reaction
  - Sn and Nb are heated to 600-700°C
  - Sn diffuses in Nb and reacts to form Nb<sub>3</sub>Sn

by A. Godeke

# Conductors: Strand and cables

- Now, we know we need conductors composed out of small filaments and surrounded by a stabilizer (typically copper) to form a multi-filament wire or strand.
- To keep voltages reasonable small, the inductance of the magnet has to be small  $\rightarrow L \propto 1/l^2 \rightarrow$  we need large currents!
- Large wires are excluded due to self-field instabilities yielding to flux jumps (same argument as for small filaments)  $\rightarrow$  practical limit 1-2 mm

**Solution:** Superconducting cable composed of several wires: multi-strand cable!

# What else do we need? Insulation!

Rule in accelerator magnets: never sacrifice the insulation!

Courtesy of A. Siemko, CERN

# Typical insulation schemes for Nb-Ti and Nb<sub>3</sub>Sn

Typically the insulation thicknesses: 100 and 200  $\mu\text{m}$

- The cable insulation must feature good electrical properties to withstand turn-to-turn V after a quench
- Good mechanical properties to withstand high pressure conditions
- Porosity to allow penetration of helium (or epoxy)
- Radiation hardness

In Nb-Ti magnets overlapped layers of polyimide

In Nb<sub>3</sub>Sn magnets, fibre-glass braided or as tape/sleeve.

# Let's take the cable and do an electromagnetic design!

- How do we express field and its “imperfections”?
- How do we create a perfect field?
- How do we design a coil to minimize field errors?
- How do we select the current density in the coil?

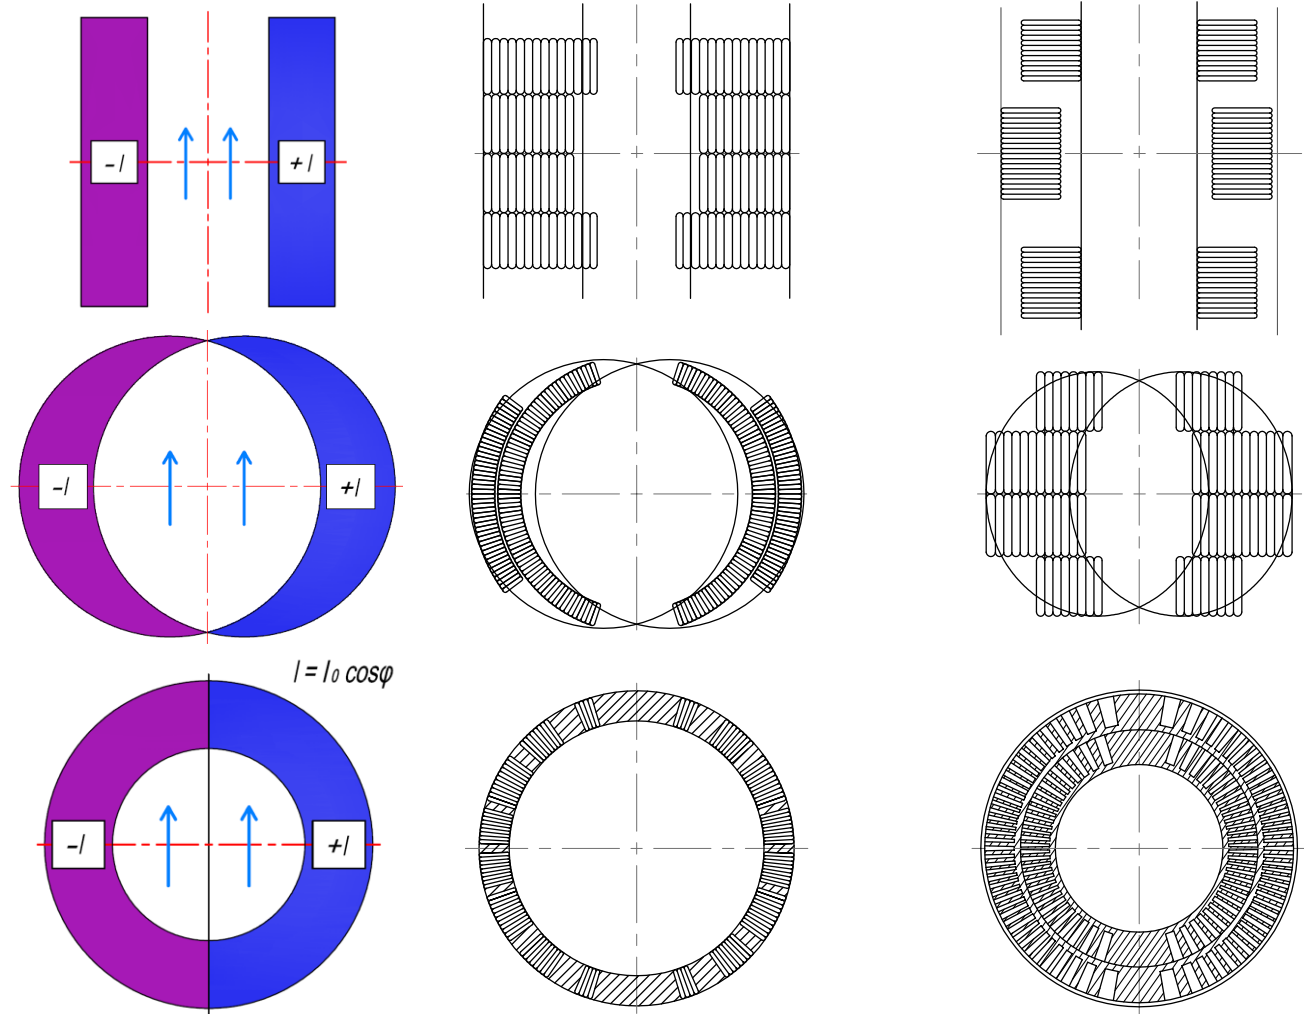

# How do we generate a perfect dipole?

- How to generate a dipolar field:
  - Two infinite slabs
  - Two intersection cylinders
  - Cos-theta current distribution
- Many different winding schemes typically classified as
  - Block type magnets (block, common-coil)
  - Cos-theta/shell type magnets (traditional cos-theta, canted cos-theta)

LHC

# Magnetic design: Harmonics

The field can be expressed as (simple) series of coefficients  
So, each coefficient corresponds to a “pure” multipolar field

$$B_y(x, y) + iB_x(x, y) = \sum_{n=1}^{\infty} C_n (x + iy)^{n-1} = \sum_{n=1}^{\infty} (B_n + iA_n)(x + iy)^{n-1}$$

by K.-H. Mess, *et al.*

# Magnetic design: Harmonics

The field can be expressed as (simple) series of coefficients  
So, each coefficient corresponds to a “pure” multipolar field

Dipole

$$B_1 = \frac{2\mu_0}{\pi} J(R_{\text{out}} - R_{\text{in}}) \sin \varphi = \frac{2\mu_0}{\pi} Jw \sin \varphi$$

$$B_n = \frac{2\mu_0}{\pi} J \frac{(R_{\text{out}}^{2-n} - R_{\text{in}}^{2-n})}{n(2-n)} r_{\text{ref}}^{n-1} \sin(n\varphi), n = 3, 5, 7, \dots$$

# Magnetic design: Optimization of one layer designs

- We compute the central field given by a sector dipole with 2 blocks
- Equations to set to zero  $B_3$ ,  $B_5$  and  $B_7$

$$\begin{cases} \sin(3\alpha_3) - \sin(3\alpha_2) + \sin(3\alpha_1) = 0 \\ \sin(5\alpha_3) - \sin(5\alpha_2) + \sin(5\alpha_1) = 0 \end{cases}$$

- And with 3 blocks
- Equations to set to zero  $B_3$ ,  $B_5$ ,  $B_7$ ,  $B_9$  and  $B_{11}$

$$\begin{aligned} \sin(3\alpha_5) - \sin(3\alpha_4) + \sin(3\alpha_3) - \sin(3\alpha_2) + \sin(3\alpha_1) &= 0 \\ \sin(5\alpha_5) - \sin(5\alpha_4) + \sin(5\alpha_3) - \sin(5\alpha_2) + \sin(5\alpha_1) &= 0 \\ \sin(7\alpha_5) - \sin(7\alpha_4) + \sin(7\alpha_3) - \sin(7\alpha_2) + \sin(7\alpha_1) &= 0 \\ \sin(9\alpha_5) - \sin(9\alpha_4) + \sin(9\alpha_3) - \sin(9\alpha_2) + \sin(9\alpha_1) &= 0 \\ \sin(11\alpha_5) - \sin(11\alpha_4) + \sin(11\alpha_3) - \sin(11\alpha_2) + \sin(11\alpha_1) &= 0 \end{aligned}$$
