

Regression: Variable Angle Electrons

Dominick Olivito (UCSD)

Overview

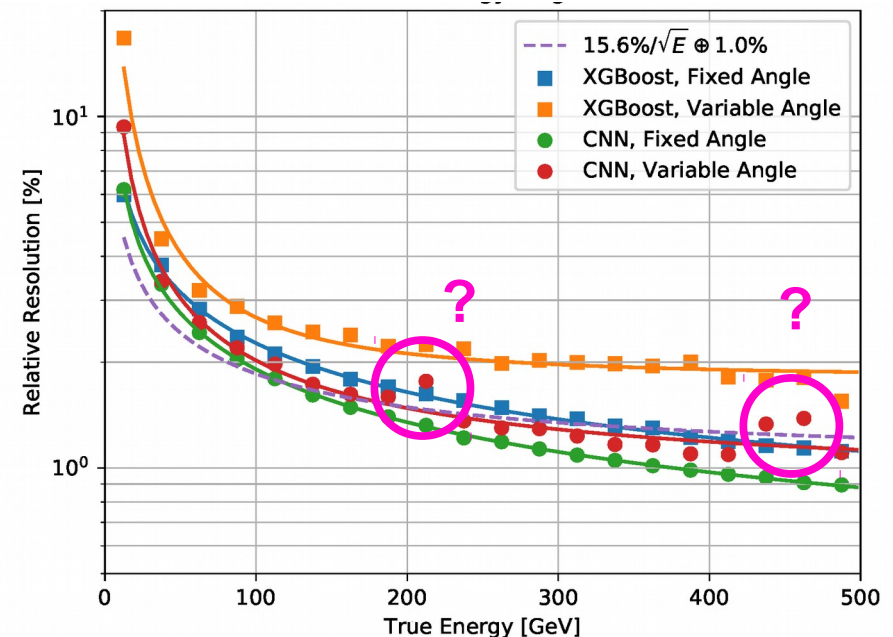

- Trying to understand why Variable Angle electron performance is worse than Fixed Angle
- See already that raw (ECAL+HCAL)/True response is different for variable angle vs fixed, so may expect differences at some level

Electrons

Previous Results

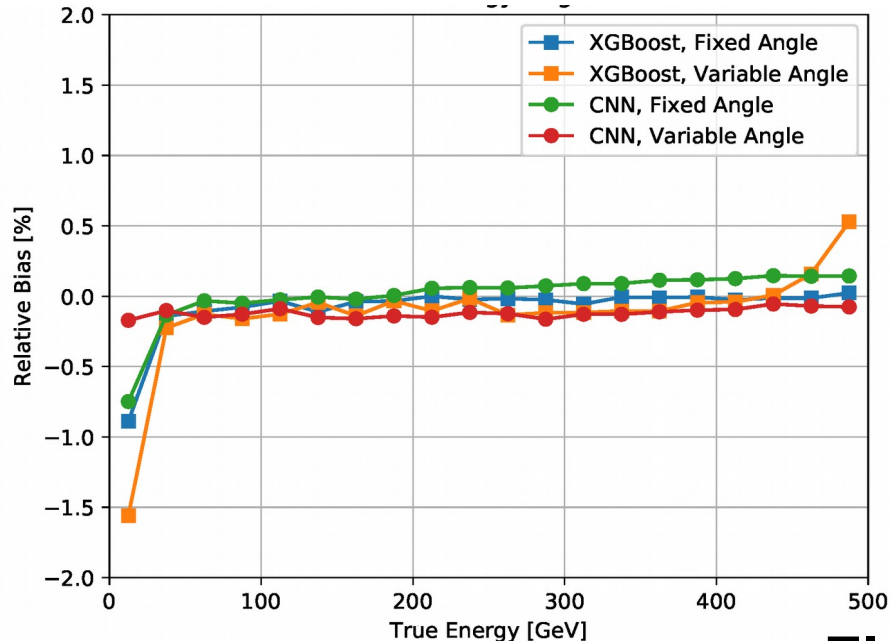

- **Substantial difference** in performance between **Fixed and Variable** angle samples, especially with XGBoost
- Less difference with CNN, but **suspicious outliers** in resolution vs energy plot
 - Using RMS → **sensitive to large outliers** in $(\text{True-Pred})/\text{True}$
 - Outliers come mainly from events with small fraction of true energy in window, or most of energy in HCAL(?)

Electrons

After Outlier Removal

- In each bin, remove events that are **more than 5 sigma (RMS) away from mean $(\text{True-Pred})/\text{True}$**
- Removes a handful of events / bin, **< 0.1% overall**
 - Could remove based on $(\text{ECAL}+\text{HCAL})/\text{True}$, didn't have ready
 - Doesn't affect Fixed Angle sample
- **Variable angle performance improves**, much closer to fixed angle now → especially for CNN

Electrons

Summary / To Do

- Some of the bad Variable Angle Electron performance was coming from events with either:
 - Very small fraction of true energy reconstructed in window, or
 - Large fraction of reco energy in HCAL (instead of 0-5%)
- Doesn't really occur in Fixed Angle sample, not sure what the difference is

- To do:
 - Check resolution vs eta
 - Check other particles

Bonus Slides

Samples / Details

- Samples: new larger window samples, fixed angle, with features
 - On culture-plate at caltech:
 - /data/shared/LCDLargeWindow/fixedangle/*Escan/*.h5
 - /data/shared/LCDLargeWindow/varangle/*Escan/*.h5
 - Slimmed versions with only features (no images):
 - /data/shared/LCDLargeWindow/fixedangle/*Escan/merged_featuresonly/
 - /data/shared/LCDLargeWindow/varangle/*Escan/merged_featuresonly/
 - ~800k events, 70% train, 30% test
- Running XGBoost in python with:
 - maxdepth 3, up to 1000 rounds
 - Early stopping if test loss doesn't improve for 10 rounds
- Running DNNs / CNNs in pytorch, python3 using Triforce
 - Dropout 0.2
 - Adam, learning rate 0.001
 - L2 regularization 0.01 (“decayRate”)
 - Train for 5-10 epochs depending on window size

Skip Connections

- Basic idea: **hardcode Identity function into network**, to make other layers learn residual correction to identity
- Appropriate for our case: we know **linear regression** in ECAL_E, HCAL_E gets **close to the right answer**
- Performance is similar, **training converges faster**
 - For Feature Based NN, in 10-20 epochs instead of 40

NIPS CNN Architecture

- Modifications:
 - 51x51x25 ECAL input
 - 11x11x60 HCAL input
 - 3 conv filters for HCAL
 - Skip connections for ECAL_E, HCAL_E
