

# TOF Resolution and Efficiency

Durga Rajaram, Scott Wilbur, Viktor Pěč

June 27, 2018

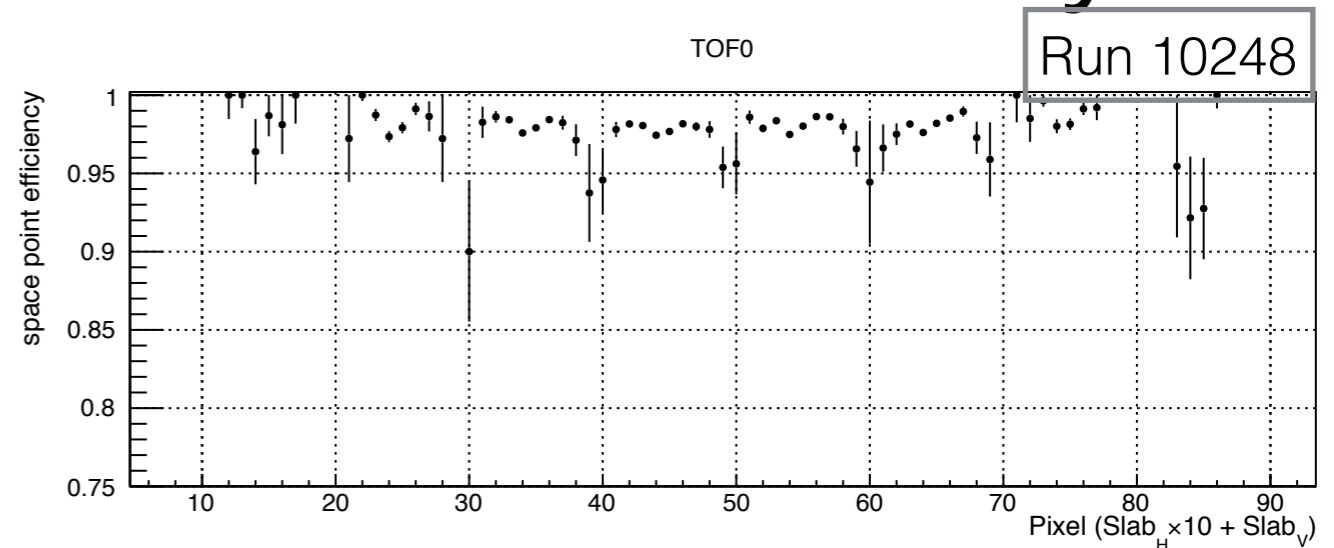

MICE CM51

# Since last CM

- 2 PMT channels in TOF1 identified with features in their ADC readings
- Both channels kept in reconstruction, ADC readings of one can be corrected
- New calibration constants produced for a subset of runs
- 2 runs were reprocessed with new calibrations for testing purposes

# Space point creation “efficiency”

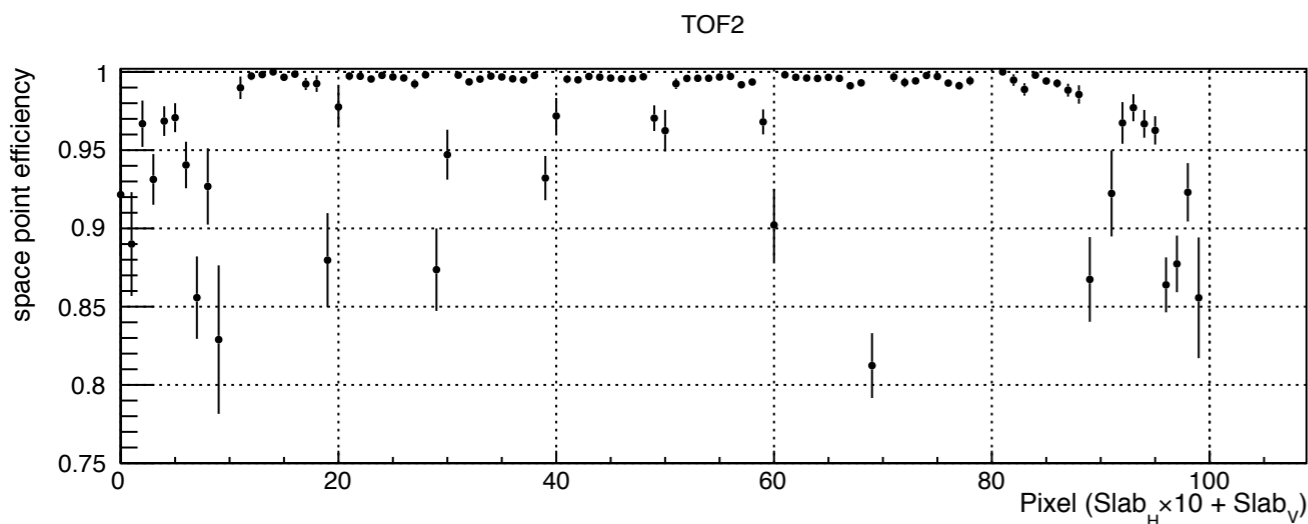

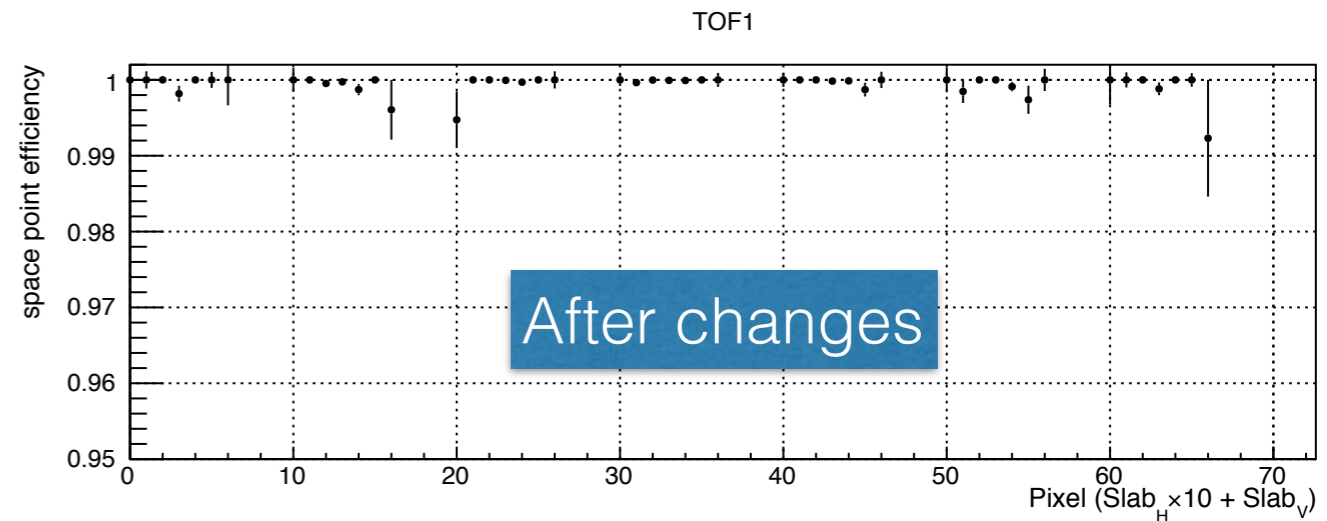

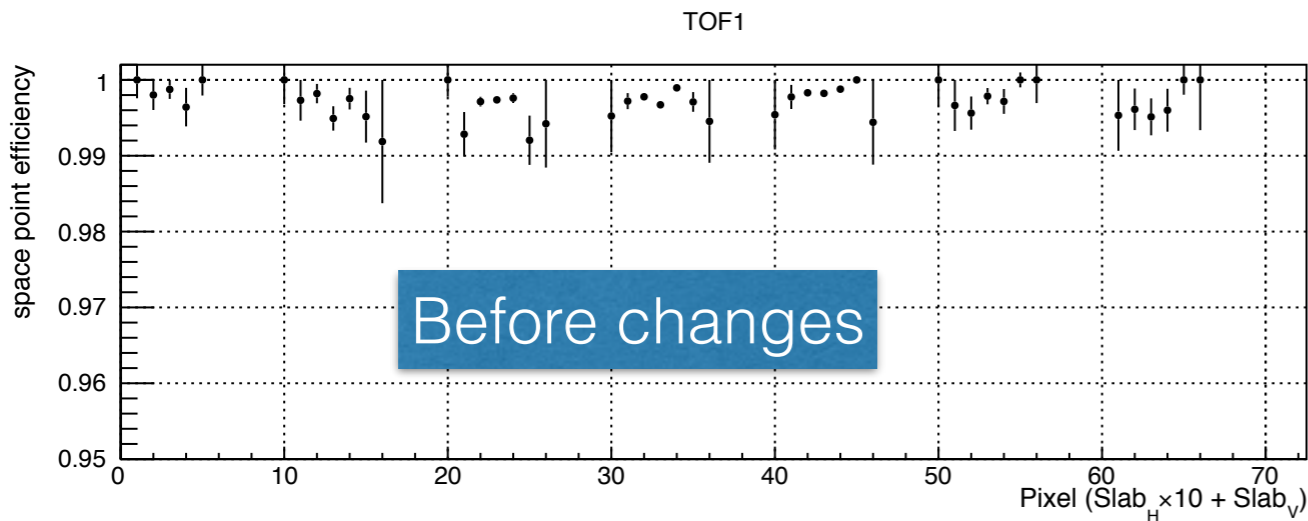

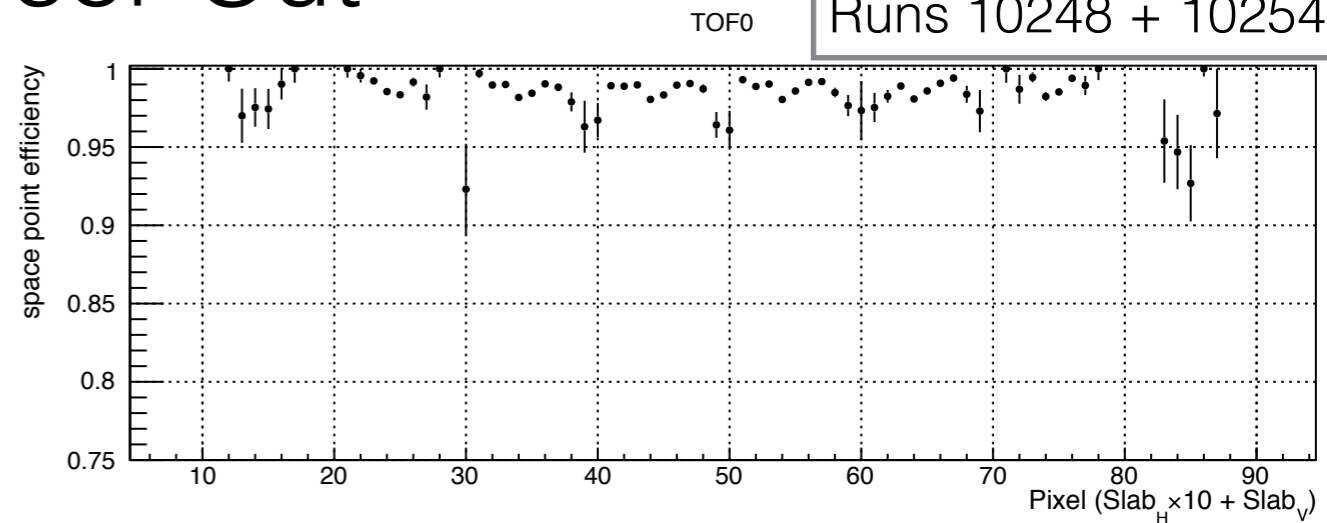

- “Efficiency” = if there are 2 slab hits, how often is a SP created
- $\Delta T$  cut was **0.5 ns**
- “Inefficient” events:
  - slab  $\Delta T$  is in the distribution’s tails and does not make the cut (**0.5 ns**)
  - 2 distinct particles give hits in 2 slabs => they don’t make slab  $\Delta T$  cut
- Low “efficiency” in quite many pixels was worrisome!
  - mostly from offsets in slab  $\Delta T$
  - We had to loosen the  $\Delta T$  cut from **0.5 ns to 3 ns**

# Comparison Before and After New Calibration and Looser Cut

Run 10248

Runs 10248 + 10254

# Space point creation “efficiency” after new calibration and looser cut

- “Inefficient” events have hits in slabs from 2 distinct particles => they don’t make slab  $\Delta T$  cut
- Latest official reconstruction exhibit worse performance:
  - We had to loosen the  $\Delta T$  cut from 0.5 ns to 3 ns
  - Redone calibrations for these runs

# TOF overall resolution

Runs 10248 + 10254

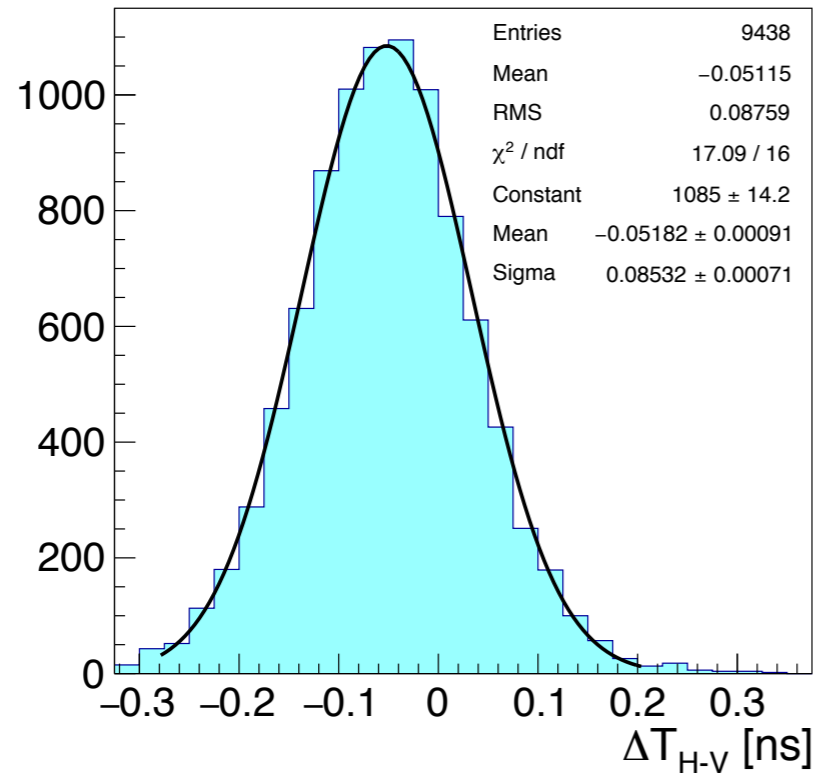

- Estimated from slab  $\Delta T$
- After modified calibrations
- $\sigma_{\Delta T}$ : TOF0  $\sim 116$  ps, TOF1  $\sim 126$  ps, TOF2  $\sim 120$  ps
- $\sigma_{\text{Station}} = \sigma_{\Delta T} / 2 =$  TOF0  $\sim$  **58 ps**, TOF1  $\sim$  **63 ps**, TOF2  $\sim$  **60 ps**
- Or  $\sigma_{\text{ToF}} = \sigma_{\Delta T} / \sqrt{2} =$  TOF0  $\sim$  **82 ps**, TOF1  $\sim$  **89 ps**, TOF2  $\sim$  **84 ps**

# Single pixel resolution

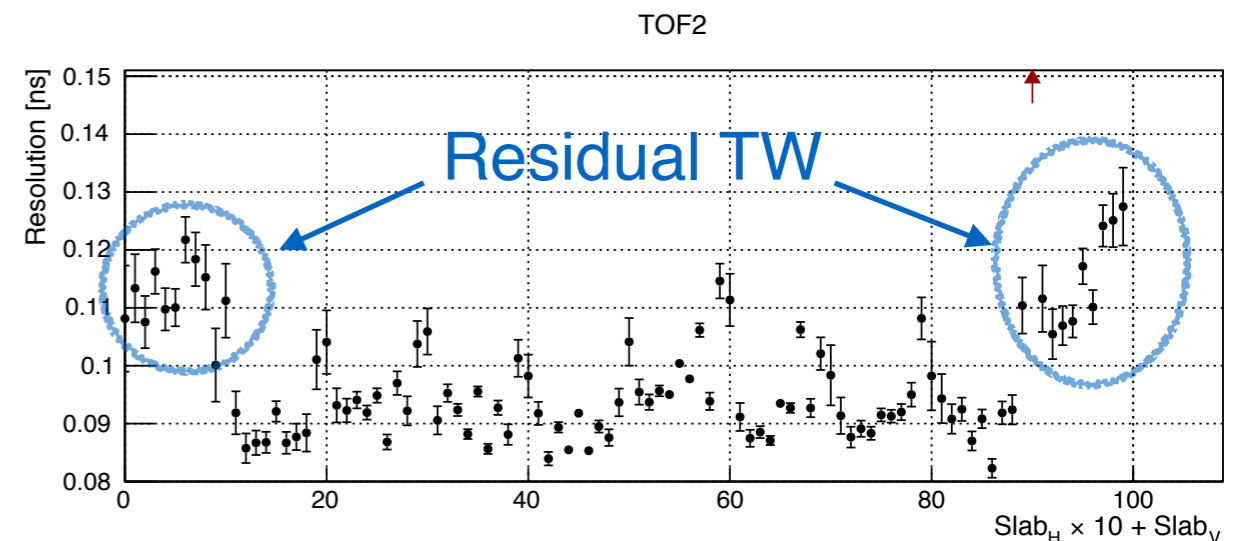

TOF2 H:4 V:6

Runs 10248 + 10254

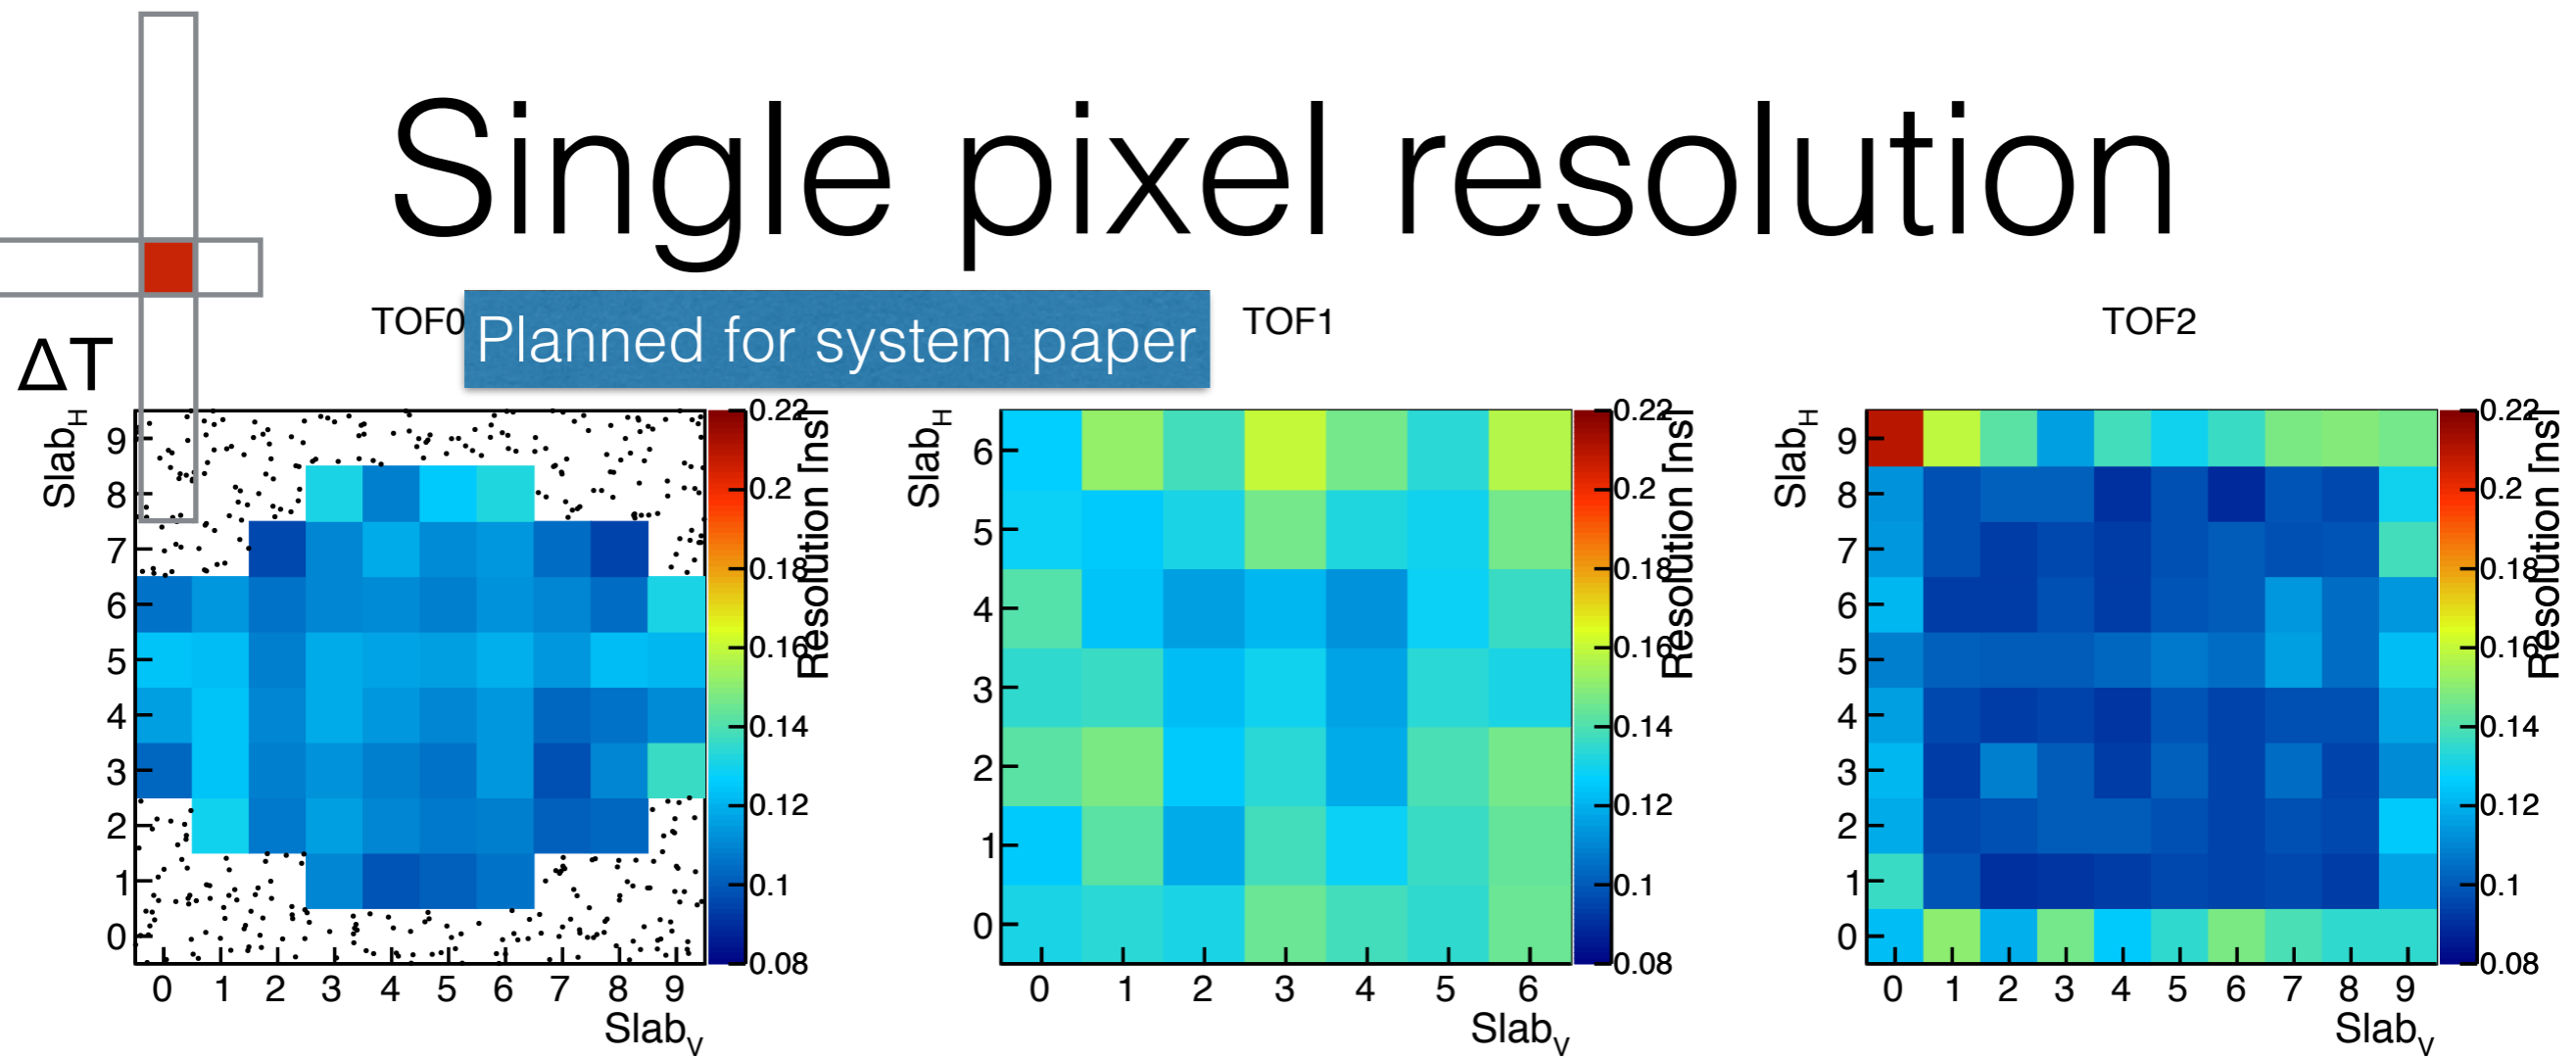

$\Delta T$

- Resolution of individual pixels varies between  $\sim 85$  ps to  $\sim 140$  ps
- Translate to T-o-F resolution  $\sim 60$  ps to  $\sim 100$  ps
- Big part of worse resolution comes from residual time walk

# Single pixel resolution

- Resolution of individual pixels varies between  $\sim 85$  ps to  $\sim 140$  ps
- Translate to T-o-F resolution  $\sim 60$  ps to  $\sim 100$  ps
- Big part of larger resolution comes from residual time walk

- Resolution uniform within the central region of each TOF

# TDC Conversion Factor - possible issue

- Conversion factor used to translate TDC counts to time units
- CAEN's V1290 specification is 25 ps per count
- MICE TOF NIMA\* paper claims measured 22 ps per count
- Nominal 25 ps per count used in current MAUS
- Possible deviation from 25 ps/count will affect calibration and T-o-F measurement of muons and pions => TOF momentum measurement
- Do we need to test used TDC boards?

\*NIM A 615 (2010) 14

# Summary

- We have improved **space-point reconstruction** by loosening cut on the constituent slabs' time difference
- Overall TOF station (T-o-F) **resolution** within about 63 ps(90 ps)
  - does not include systematic uncertainty from calibration
- Individual pixels have **slab  $\Delta T/T$ -o-F deviations** which are difficult to calibrate out
- TOF figures were proposed to be added to the **System Performance paper** - after some discussions with Paolo
- We need to resolve uncertainty on **TDC conversion factor**
- We will redo calibrations and reconstruction for full Step IV data
- Still need to understand systematics from the calibration method
- We want to include MC for comparison of main performance figures
