# 🔗 BioDynaMo overview

- Large-scale platform for biological simulation
- Started in 2015 as a CERN openlab summer student project
- International collaboration

#### Context

Future work

# Ø BioDynaMo status

- Support different specialities
- Scale up nicely (see status report in 2017)
- Does not scale *out*, yet
  - Konstantinos Kanellis prototyped a message passing layer last summer

# My work

- 1. Small fry
  - Touch up last summer code
  - Reorganize demos and tests
- 2. Big fish
  - Implement a proof-of-concept to scale *out* with distributed computing

・ロト ・ 日 ・ ・ 日 ・ ・ 日 ・ ・ つ へ ()

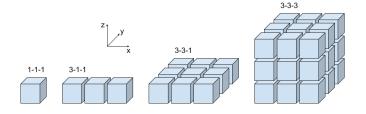

## Project status Small fry

### 1. Last summer code

- 1.1 had third party dependencies (ZeroMQ libraries) built and packaged up
- 1.2 is now buildable from fresh checkout
- 1.3 is in distribution branch
- 2. Demos and tests are
  - 2.1 now organized into a more standard structure
  - 2.2 more conveniently copied out with biodynamo demo command
  - 2.3 automatically tested by Travis CI in every commit
  - 2.4 merged in master

## Project status Big fish (the work)

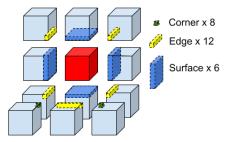

- Proposed to use Berkeley RISELab's Ray distributed execution engine
  - Stand on giant's shoulder
- Implemented a general axis-aligned 3D cube partitioning / work distribution scheme

Future work

## Project status (cont.) Big fish (the work)

• The partitioner knows about "halo" (border) regions.

• There are maximumly 8 corner regions, 12 edge regions, and 6 surface regions neighboring any particular main cube.

## Project status (cont.) Big fish (the work)

- Cubes are logical view of tasks.
- Each task comprises of 3 steps:
  - Reassembling all 26 neighboring regions and this cube from last time-step into 1 bigger cube
  - Executing one time-step simulation in this merged cube
  - Disassembling the cube back into 27 overlapping regions for the next time-step
- Python driver builds task dependency tree, and Ray manages/schedules the tasks.
- Python driver uses ctypes to load and invoke functions in C++ shared library.

## Project status (cont.) Big fish (the results)

- Sample demo distributed can be built from fresh checkout with all prebuilt dependencies packaged up.
- The driver can execute the demo in a Ray cluster, or as a local process.
- Distributed execution is transparent to the simulation code. Virtually no change to existing C++ code is required.
- There is large overhead in disassembling (serialization) and reassembling (deserialization) (up to 90% of execution time).
- Simulation objects are assumed to not move across regions.
- All code is in experimental-ray branch.

Future work

・ロト ・ 日 ・ ・ 日 ・ ・ 日 ・ ・ つ へ ()

## Future work

- Reconcile the movement of simulation objects
  - From a remote region moving into a main region
  - From a remote region moving into another remote region
  - From a main region moving outside
  - Farther than the halo distance
- Alleviate serialization / deserialization
- Ensure that tasks are given to nodes owning largest blobs
- Ensure deterministic PRNGs on different workers
- Support resuming simulation when needed
- Most importantly, validate the correctness of distributed execution
