

# Singlet-like scalars at HL and HE LHC

Dario Buttazzo, Filippo Sala, Andrea Tesi

HL-HE LHC Workshop, WG3 Meeting — 22 May 2018

# Higgs physics at HL and HE LHC

---

LHC will be able to measure Higgs couplings with a precision of a few %

| Coupling        | Uncertainty (%)      |            |                       |            |
|-----------------|----------------------|------------|-----------------------|------------|
|                 | 300 fb <sup>-1</sup> |            | 3000 fb <sup>-1</sup> |            |
|                 | Scenario 1           | Scenario 2 | Scenario 1            | Scenario 2 |
| $\kappa_\gamma$ | 6.5                  | 5.1        | 5.4                   | 1.5        |
| $\kappa_V$      | 5.7                  | 2.7        | 4.5                   | 1.0        |
| $\kappa_g$      | 11                   | 5.7        | 7.5                   | 2.7        |
| $\kappa_b$      | 15                   | 6.9        | 11                    | 2.7        |
| $\kappa_t$      | 14                   | 8.7        | 8.0                   | 3.9        |
| $\kappa_\tau$   | 8.5                  | 5.1        | 5.4                   | 2.0        |

Extended Higgs sectors: take a simple scenario w/ large effects due to tree-level mixing with new states

How do direct searches compare with these results?

# A simple reference case

---

At the risk of being trivial... Take just the SM + scalar singlet

- ▶ Low energy effective theory of Mirror/Twin Higgs models
- ▶ Realised in the NMSSM
- ▶ Paradigm for 1st order ElectroWeak phase transition
- ▶ ...

- ▶ can be singly produced
- ▶ decays to SM particles
- ▶ modified Higgs couplings

easy enough to test capabilities of LHC and future colliders with just a few meaningful parameters

# Higgs-singlet mixing: main features

SM + 1 real singlet:  $H = (i\pi^+, \frac{v+h^0+\pi^0}{\sqrt{2}}), \quad S = v_s + s^0.$

Mass eigenstates:  $h = h^0 \cos \gamma + s^0 \sin \gamma, \quad \phi = s^0 \cos \gamma - h^0 \sin \gamma.$

The phenomenology mainly depends on only 3 parameters:

$$\begin{aligned}\mu_h &= c_\gamma^2 \times \mu_{\text{SM}}, \\ \mu_{\phi \rightarrow VV, ff} &= s_\gamma^2 \times \mu_{\text{SM}}(m_\phi) \times (1 - \text{BR}_{\phi \rightarrow hh}), \\ \mu_{\phi \rightarrow hh} &= s_\gamma^2 \times \sigma_{\text{SM}}(m_\phi) \times \text{BR}_{\phi \rightarrow hh},\end{aligned}$$

$\phi$  is like a heavy SM Higgs, with narrow width +  $hh$  channel

# Higgs-singlet mixing: main features

SM + 1 real singlet:  $H = (i\pi^+, \frac{v+h^0+\pi^0}{\sqrt{2}}), \quad S = v_s + s^0.$

Mass eigenstates:  $h = h^0 \cos \gamma + s^0 \sin \gamma, \quad \phi = s^0 \cos \gamma - h^0 \sin \gamma.$

The phenomenology mainly depends on only 3 parameters:

$$\begin{aligned}\mu_h &= c_\gamma^2 \times \mu_{\text{SM}}, \\ \mu_{\phi \rightarrow VV, ff} &= s_\gamma^2 \times \mu_{\text{SM}}(m_\phi) \times (1 - \text{BR}_{\phi \rightarrow hh}), \\ \mu_{\phi \rightarrow hh} &= s_\gamma^2 \times \sigma_{\text{SM}}(m_\phi) \times \text{BR}_{\phi \rightarrow hh},\end{aligned}$$

$\phi$  is like a heavy SM Higgs, with narrow width +  $hh$  channel

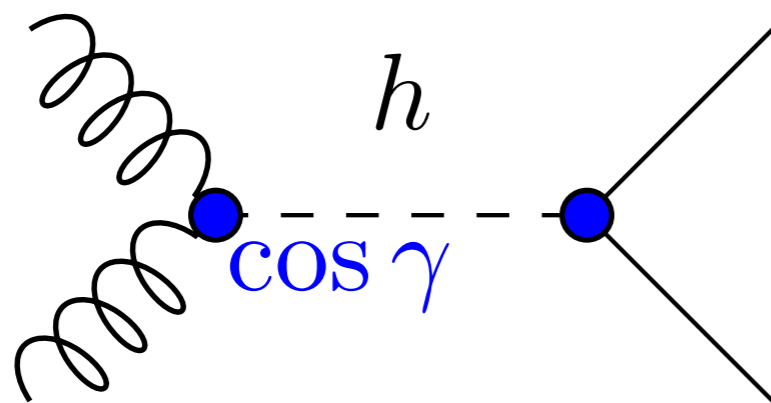

At high mass the equivalence theorem relates the decay widths

$$\text{BR}_{\phi \rightarrow hh} = \text{BR}_{\phi \rightarrow ZZ} = \frac{1}{2} \text{BR}_{\phi \rightarrow WW} \simeq \frac{1}{4}, \quad m_\phi \gg m_h$$

(these are the dominant channels, fermionic modes suppressed)

Two complementary ways to look for the extra Higgs:

Higgs signal strengths

$$\mu_h = c_\gamma^2 \mu_{\text{SM}}$$

Direct searches

$$\mu_\phi = s_\gamma^2 \mu_{\text{SM}} \times (1 - \text{BR}_{\phi \rightarrow hh})$$

➔ Direct reach of HL and HE LHC vs Higgs measurements?

# Extrapolation of the limits

Estimate the bounds as follows:  $\text{significance} = \frac{S}{\sqrt{S + B + \alpha_{\text{sys}}^2 B^2}} \gtrsim 2$

$S_{95\%} \approx 2\sqrt{B + \alpha_{\text{sys}}^2 B^2}$  limit on the cross-section is determined by the number of background events around the resonance peak

► Rescale LHC data with the parton luminosity of the bkg

see also Salam, Weiler '14; Thamm, Torre, Wulzer '15

$$\begin{cases} N_B(s_0, L_0, m_0) = N_B(s, L, m) & \rightarrow m = m(m_0) \\ N_S(s_0, L_0, m_0) = N_S(s, L, m) & \rightarrow \sigma(m) = (L_0/L) \sigma_0(m_0) \end{cases}$$

# Reach of LHC and future upgrades

# Reach of LHC and future upgrades

- Updated limits using 13 TeV data: good agreement with previous results from 8 TeV
- Extrapolation from 13 to 14 TeV is more robust
- Agreement – up to  $O(1)$  factors – with other studies at 13, 14, 27 TeV

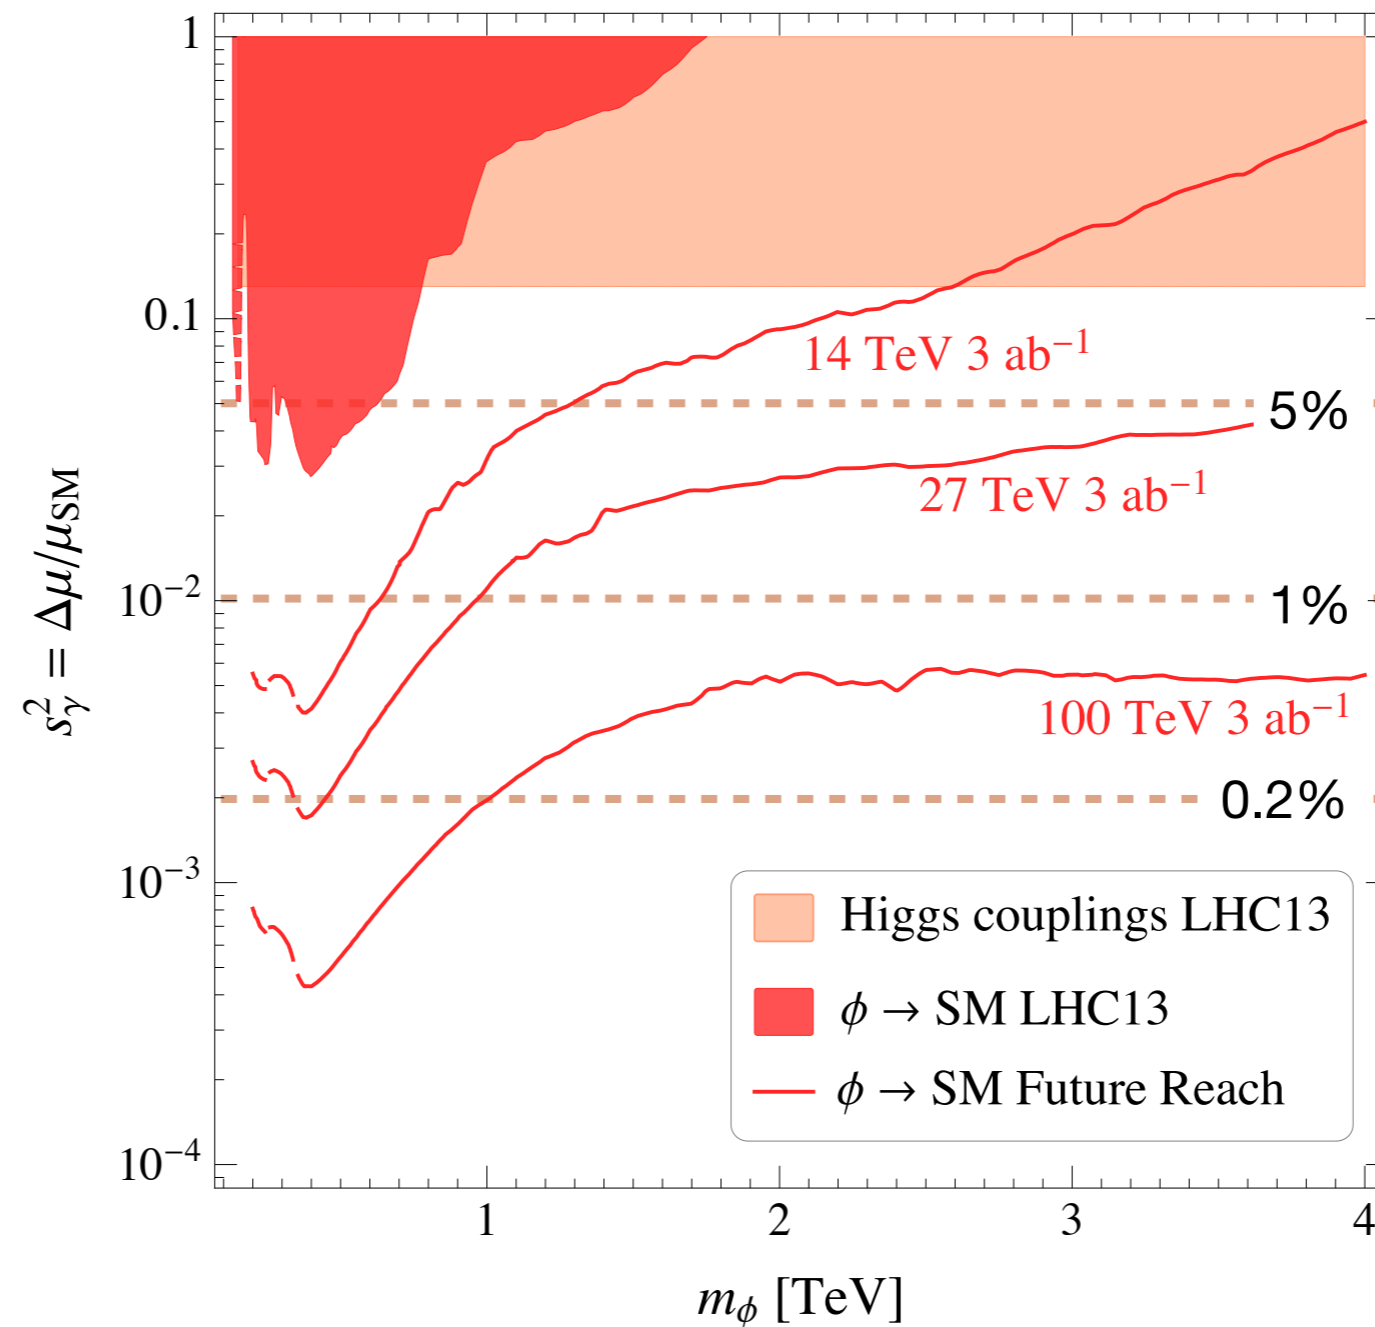

Brownson et al. '13  
Gouzevich et al '13

- The excluded cross-sections scale as (parton luminosity)<sup>1/2</sup>  
(below a certain mass SM thresholds become important: we don't extrapolate the limits beyond that point)

# Direct vs indirect

- Easy to compare the limits with indirect bounds from Higgs couplings

direct searches dominate at low mass (at each stage of the experimental program)

# SUSY: the NMSSM

$$\mathcal{W} = \mathcal{W}_{\text{MSSM}} + \lambda S H_u H_d + f(S)$$

- ◇ Extra tree-level contribution to the Higgs mass

$$M_{hh}^2 = m_Z^2 c_{2\beta}^2 + \lambda^2 v^2 s_{2\beta}^2 + \Delta^2$$

- ◇ Alleviates fine-tuning in  $v$  for  $\lambda \gtrsim 1$  and moderate  $\tan \beta$

Recast the previous bounds:

$$\sin^2 \gamma = \frac{M_{hh}^2 - m_h^2}{m_\phi^2 - m_h^2}$$

$$M_{hh}^2 = m_Z^2 c_{2\beta}^2 + \lambda^2 v^2 s_{2\beta}^2 + \Delta^2$$

loop correction  
to Higgs mass  
from top-stop

already now direct searches  
more stringent than Higgs fit

# Twin Higgs

- ▶ Higgs mass is protected from radiative corrections, **without coloured states at the weak scale.**
- ▶ Linear  $\sigma$ -model: there is a “radial mode” with mass  $m_\sigma^2 \approx \lambda_* f^2$ .
- ▶ The model is fully determined by 4 parameters:  $m_\phi, m_h, v, f$ .

$$M_{hh}^2 = (m_\sigma^2 + m_h^2)(v^2/f^2),$$

$$\sin^2 \gamma \sim v^2/f^2$$

If not too strongly coupled the  
Twin Higgs could be directly visible

# Summary & Outlook

---

- ✓ Looking for singlets is easy, and motivated by many (natural) models
- ✓ General description in terms of a few physical parameters: a simple reference case for the study of extended Higgs sectors
- ✓ Direct searches are a powerful probe: assess reach of HL and HE LHC

Higgs couplings become more important for NP above  $\sim$  a TeV

- ➔ For the report: update all the bounds with most recent data, PDF, etc...
- ➔ More detailed study of EW phase transitions (case of small mixing)
- ➔ more suggestions, comments?

Backup

# Generic singlet: comparison of bounds

Direct searches dominate for low  $m_\phi$ ,  $M_{hh}$ : look for the singlet!

# Higgs couplings

Very large modifications of the triple Higgs coupling are possible:  
in principle observable at the LHC

# Extrapolation of bounds

$N_B(m_0, s_0, L_0) = N_B(m, s, L')$  implies

$$\sum_{\{i,j\}} c_{ij} \frac{d\mathcal{L}_{ij}}{d\hat{s}}(s, m^2) = \frac{L_0}{L'} \sum_{\{i,j\}} c_{ij} \frac{d\mathcal{L}_{ij}}{d\hat{s}}(s_0, m_0^2),$$

which implicitly determines  $m(m_0, L')$ , for any  $L'$ .

For each  $m$ ,  $L_0 \leq L' \leq L$  is chosen as to maximise the exclusion

$$[\sigma \times \text{BR}](m; s, L) = \min_{L' \leq L} \left[ \frac{L_0}{\sqrt{LL'}} [\sigma \times \text{BR}]_0(m_0; s_0, L_0) \Big|_{m_0(L')} \right]$$

(we use a  $\sqrt{L'/L}$  rescaling from  $L'$  to the nominal  $L$ ).
