

# CMS Simulation Software

Vladimir Ivanchenko  
Tomsk State University & CERN  
MixMax workshop

# Outline

- ❖ CMS detector
- ❖ CMS simulation scheme
- ❖ Random engine in CMSSW
- ❖ CMSSW validation
- ❖ Discussion

# CMS Detector

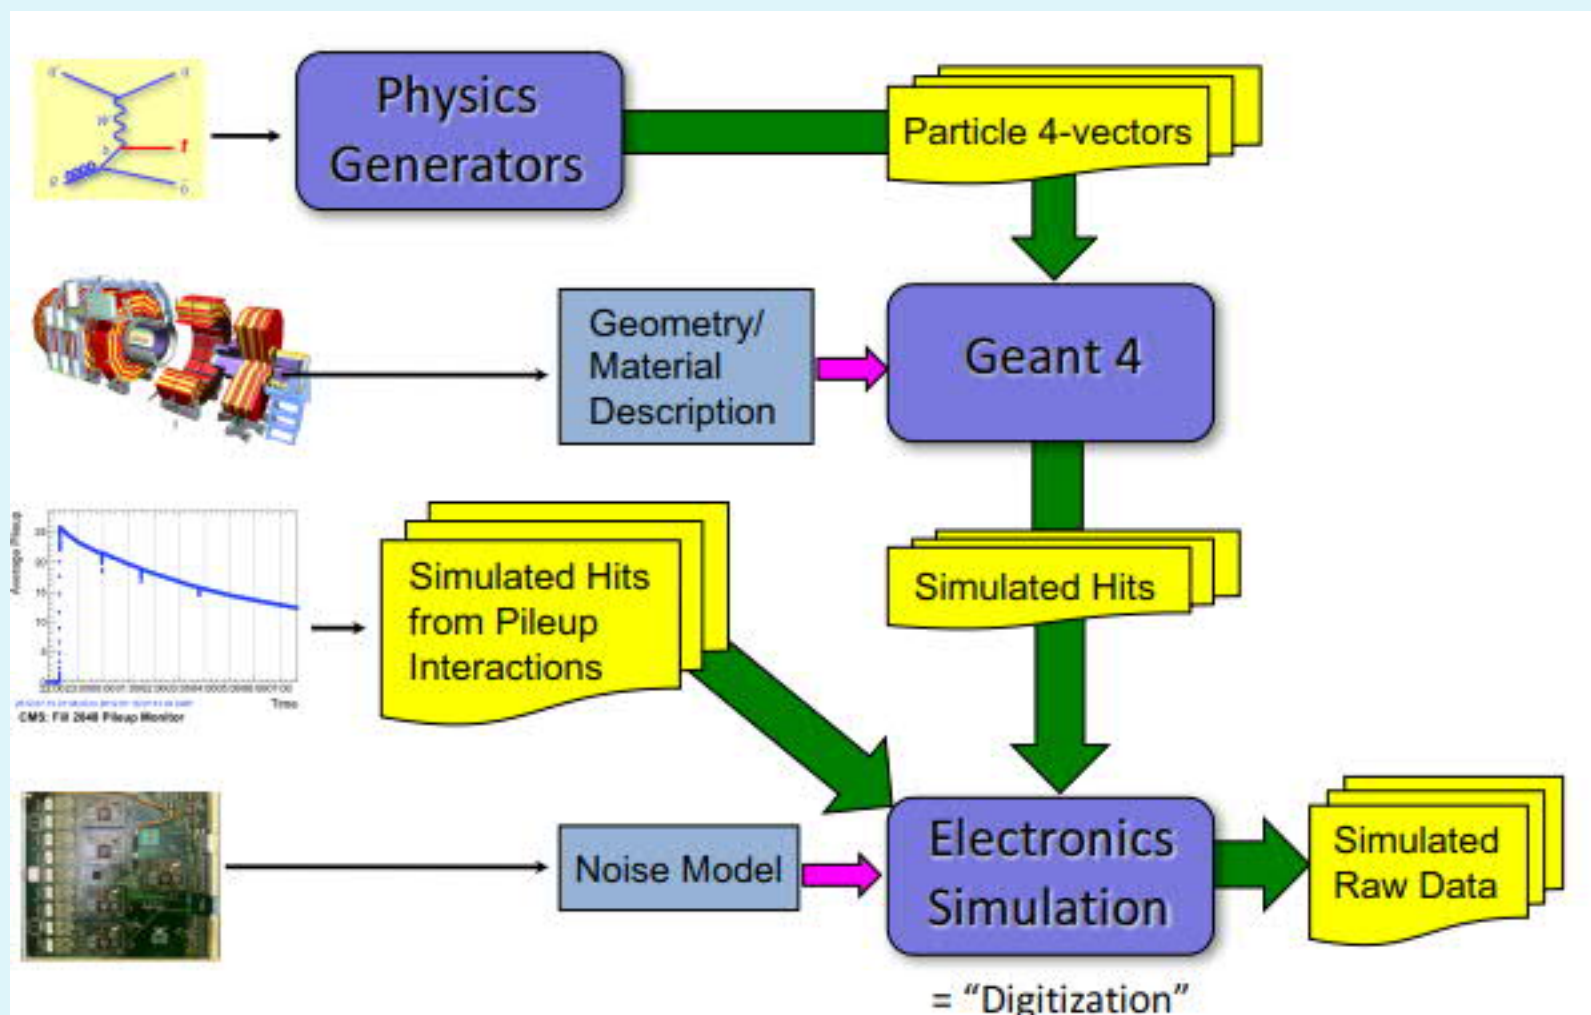

# CMS Software

- ❖ CMS framework responsible for processing of all type of computation for the CMS experiment
  - ❖ Online data acquisition and monitoring
  - ❖ High level trigger
  - ❖ Simulation
  - ❖ Reconstruction
  - ❖ Preparation of analysis
- ❖ CMSSW framework call execution of Producer
  - ❖ Producers are executed one by one
  - ❖ Each may use data from previous Producers and produce new data
  - ❖ Sequence of Producers may be interrupted and data may be stored into ROOT persistent files
  - ❖ Data may be retrieved from the ROOT input file and sequence of producers will be further executed
- ❖ Normally, results of Geant4 simulation are stored
  - ❖ It is the most time consuming part
- ❖ Digitization and reconstruction are performed in a separate run
  - ❖ Usually repeted more than once

# CMS Monte Carlo Approach

# CMS simulated event

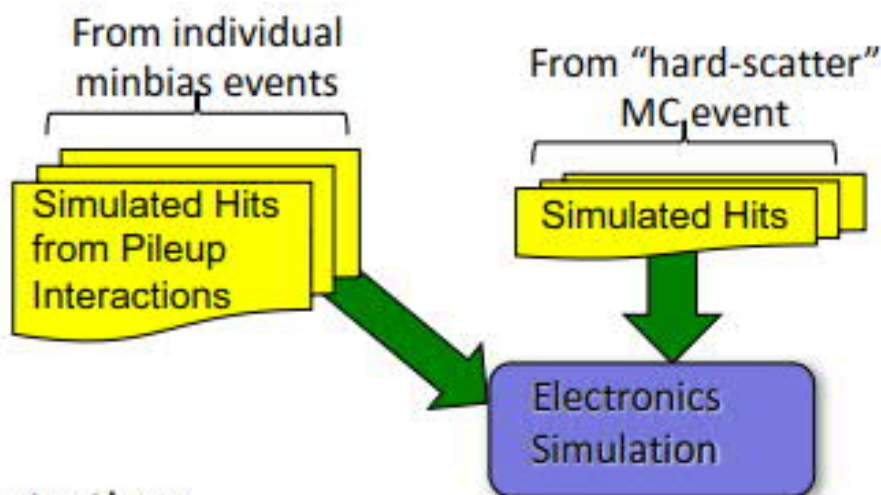

# CMS simulation faces significant challenges for both today and tomorrow

- ❖ Higher LHC luminosity means:
  - ❖ Need for more accurate simulations
  - ❖ Need for more events (ideally more events/CHF)
  - ❖ More demanding pileup simulation requirements
  
- ❖ Major detector upgrades :
  - ❖ First was done in 2017
  - ❖ Second was for 2018
  - ❖ Next will follow during LS-2 and for HL-LHC
    - ❖ New detector concepts to develop, benchmark and validate
    - ❖ The need to make reliable simulations for HL-LHC luminosities

# Simulating extreme luminosities

- Model pileup by including G4hits from MinBias events generated separately from the hard-scatter event

- Hits are loaded one interaction at a time, processed and accumulated for the final digitized output

- The pileup interaction simulation is the sum of many interactions

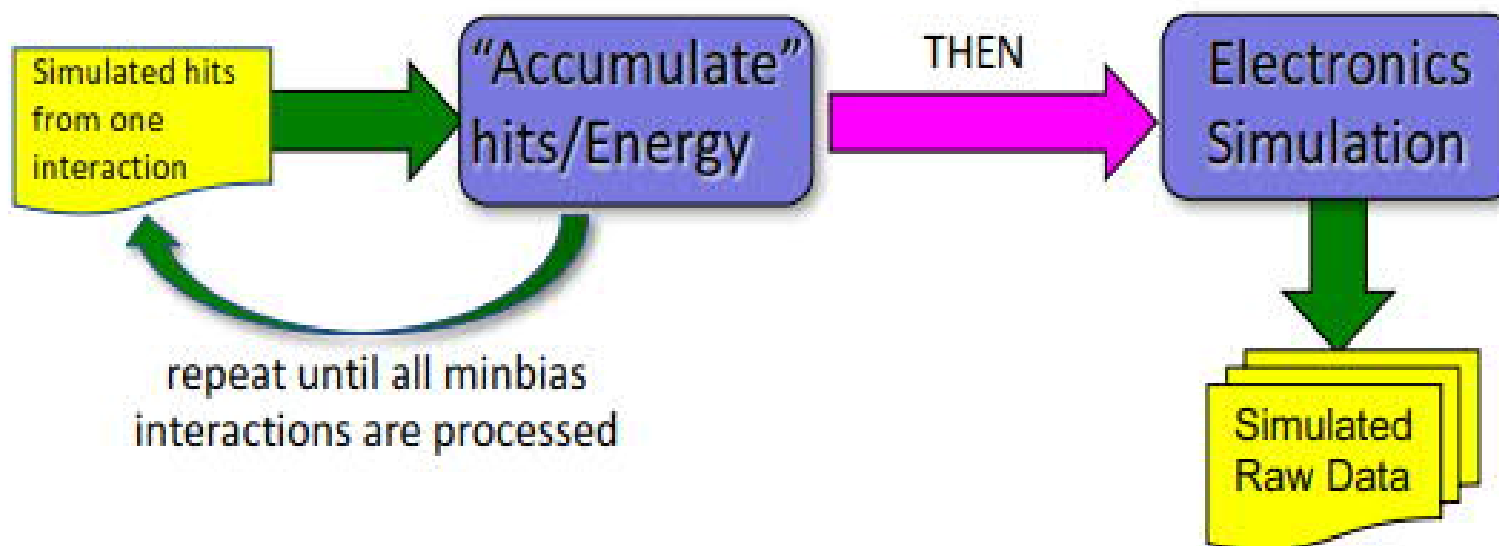

Tens or hundreds of interactions per bunch crossing

# Pre-mixing of pile-up events

- Newly deployed solution: “Pre-Mixing” which proceeds in 2 steps
  1. Upfront I/O intensive step: Create library of events containing only pileup contributions

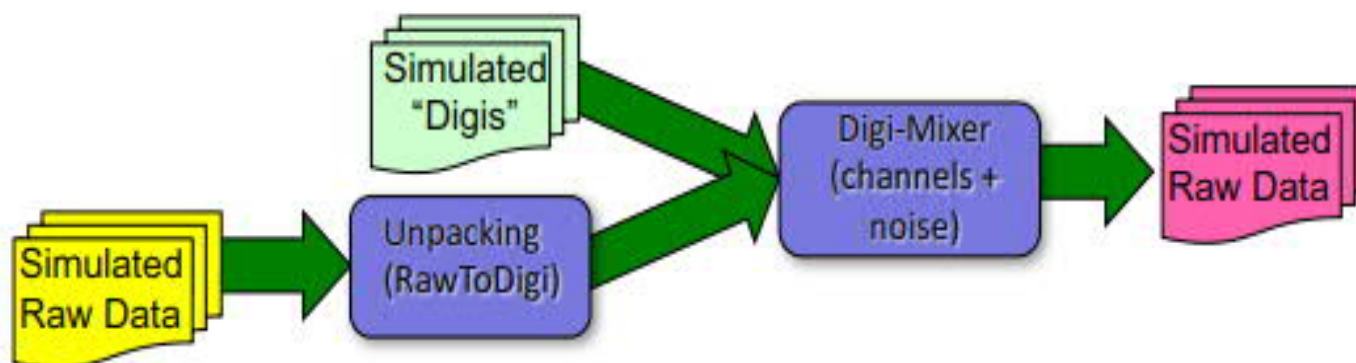

# Raw data format at the end of the simulation chain

- The hard-scatter sample is created and processed through the digitization step with no pileup, convert to our raw data format

- Then the two streams are merged

- Only 1 pileup event is needed for each "hard scatter" MC event
  - Much easier to process through computing infrastructure once the premixing sample is created

# Premixing lessons learned

- ❖ After a long development and validation process, **premixing deployed in CMS MC production** since 2016
  
- ❖ **Issues and benefits we found**
  - ❖ Extended “raw” format extended to ensure **sufficient precision** for closely interactions
  - ❖ **Event reuse**: We now potentially re-use entire pileup events instead just individual minimum bias events in Monte Carlo production
  - ❖ **Flexibility** considerations: Generating multiple pileup configurations is now more time consuming
  - ❖ **Major CPU savings**: At current pileup, our digitization+reconstruction processing runs ~2x faster (with a one time cost of the up front production of the premixed library)

# Premixing library

- ❖ The premixing library is big ( $\sim 0.1 * N(\text{PU})$  MB/event)
  - ❖ Must save sufficient information from the pileup events to allow an accurate digitization
  - ❖ This is still a huge savings over the I/O seen in our old approach ( $\sim 40x$ ). We can run production using remote reads of premixing library
  - ❖ Premixing has brought a substantial operational improvement to CMS operations

# CMS Simulation production for Run-2

- ❖ For 2015-2016 data analysis Geant4 10.0p02 was used and about 18 billion events were produced
- ❖ For 2017 data analysis Geant4 10.2p02 was used and about 10 billion events were produced
- ❖ 2018 production is not yet started
  - ❖ Geant4 10.4 is prepared
  - ❖ CMS switched to MixMax

# Random number service in CMSSW

- ❖ Each CMSSW Producer may call CMSSW Service
  - ❖ One of Service classes is RandomGeneratorService
    - ❖ It allows to create random generator engine and initialize it for the Producer
    - ❖ Initilisation of the engine is done
      - ❖ via configurable parameters
      - ❖ Via event record
- ❖ In the case of Geant4 simulation the RandomGeneratorService initialize CLHEP random engine

# CMS Random number generators

- ❖ Random number generators were available:
  - ❖ RanecuEngine
  - ❖ HepJamesRandom
  - ❖ TRandom3
- ❖ MixMax was 1<sup>st</sup> added to the list without real use
  - ❖ Fall of 2017
- ❖ CMS configure by default
  - ❖ For 22 producers the defaults was HepJamesRandom
    - ❖ SIM, DIGI
  - ❖ For 17 producers the default was TRandom3
    - ❖ FastSIM and RECO
  - ❖ There are , at least, one place in RECO where std::random is used
- ❖ Seeding is done per event

# Why transition to MixMax is useful to CMS?

- ❖ MixMax demonstrate slightly better CPU performance compared to other generators
  - ❖ HepJamesRandom, TRandom3 have nearly the same speed but are a bit slower
- ❖ Potentially MixMax allowing remove non-reproducibilities in MT runs
  - ❖ MixMaxRng::setSeed(long seed) is reproducible
  - ❖ Seed may be defined via some formula depending on run number and event number
- ❖ MixMax generator demonstrates the best random properties

# How MixMax was proposed to CMS

Generator	N random bits	Internal data size	Period $\log_{10}(q)$	TestU01
RanecuEngine	32	430	18	Fails miserably
HepJamesRandom	32	97	43	Fails miserably
TRandom3	32	624	6000	3 tests fail
<b>MixMax</b>	<b>61</b>	<b>38</b>	<b>294</b>	<b>All pass</b>

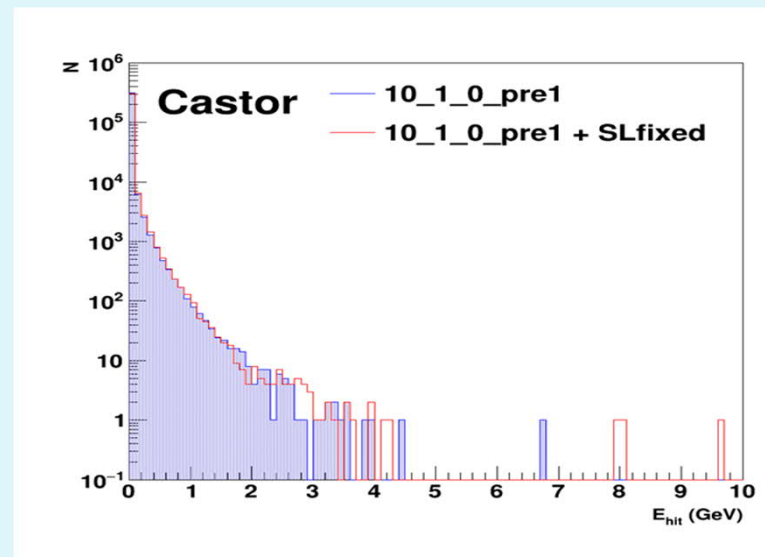

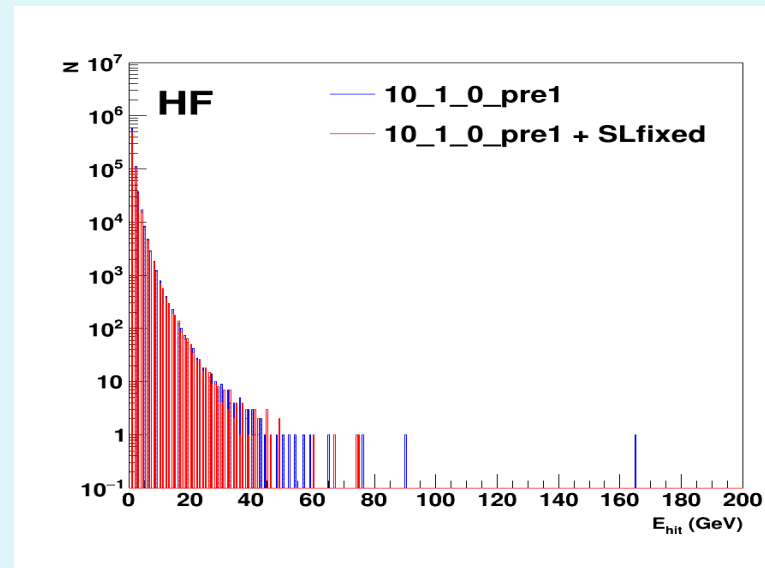

- ❖ The table is from G. Savvidy for TestU01: A C Library for Empirical Testing of Random Number Generators, P. L'ECUYER and R. SIMARD (160 tests):
- ❖ MixMax obviously have better random properties, which may be essential for HL-HLC
- ❖ It was decide adopt MixMax for 2018 massive production

# Validation of CMSSW

- ❖ Any increment of CMSSW is proposed in a form of git pool request, each is tested
  - ❖ on code rule via clang code analyzer
  - ❖ On compilation
  - ❖ On unit tests
  - ❖ On set of ~20 WF with regression versus reference version
    - ❖ About  $2 \cdot 10^6$  plots used for regression test
    - ❖ Statistics is limited to 10 events
- ❖ Any reference version is tested with a set of ~20 WF with high statistics  $10^4$  events
  - ❖ Sub-detector and physics analysis groups analyze the results and each sign or reject this reference version
  - ❖ If any of  $2 \cdot 10^6$  plot statistically disagree with the previous reference version the explanation of the discrepancy is required

# Comparisons of 10k MinBias events

# Current status of 2018 simulation

- ❖ The CMSSW release is cut just last week
  - ❖ MixMax is now the default for all SIM, DIGI FastSim Producers
  - ❖ TRandom3 is still used by RECO
- ❖ There are some problems in SIM/DIGI which show non-statistical disagreements for muon system
  - ❖ Only for the case of pile-up 50
  - ❖ Change is beyond statistics when compiler changed from gcc6.3 to gcc7.0
  - ❖ Similar differences when we switch from ClassicalRK4 stepper to DormandPrince475
- ❖ Main problem remains: how to achieve full reproducibility – results should be the same event if number of threads is different

# Discussion

- ❖ How validate correctness of usage of random generator engines for huge detector?
- ❖ How many pileup events to generate if we know number of desired experiment events and mean pile-up?
- ❖ How to handle large fluctuations in a pile-up samples, which may be overlay with different generator events?
