Combination of HH searches with the CMS experiment

UNIVERSITY of FLORIDA

on behalf of the CMS Collaboration

Double Higgs Production at Colliders workshop Fermilab, September 4th, 2018

HH and the Higgs boson trilinear coupling

$$V(\Phi^{\dagger}\Phi) = -\mu^2 \Phi^{\dagger}\Phi + \lambda (\Phi^{\dagger}\Phi)^2$$

g

Direct determination of the shape of the scalar potential λ

Luca Cadamuro (UF)

Higgs boson pair production A milestone in the exploration of the scalar sector

Experimentally difficult because of the **tiny cross** section \Rightarrow improve the sensitivity by combining several decay channels

 $\sigma_{\rm HH}^{\rm SM} = 33.49^{+7.3\%}_{-8.4\%} \text{ fb} (\text{scale} \oplus \rm PDF \oplus \alpha_{\rm S} \oplus m_{\rm t})$

JHEP 04 (2016) 126

Benchmark signal shapes

- A point in EFT can be mapped with its shape and cross-section

Luca Cadamuro (UF)

sampled signals shape benchmark point

more details in Alexandra's talk

Exploring HH production

Luca Cadamuro (UF)

10⁻¹ 10⁻² 10⁻³ 10⁻⁴ 10⁻⁵ **10⁻⁶**

rarer

- Run II: an opportunity for HH because of the increase in the cross section
- Rich phenomenology with many final states accessible at the LHC
- Four final states explored by CMS at 13 TeV in a variety of topologies
 - similar sensitivity to SM production
 - complementary sensitivity to different BSM models

PRD 96 (2017) 072004

Run I CMS combination

Luca Cadamuro (UF)

0

bbbb

- 4 analyses covering reson _ and nonresona production in resolved, semiboosted a boosted topologies
- Different trigge background estimation, and signal extractic techniques, ph space overlap

Luca Cadamuro (UF)

 $bb\tau\tau$

talk by L. C.

2 analyses covering resolved (resonant and nonresonant) and boosted τ topologies

Analysis strategies tailored to final state topology

ber 4th, 2018

Ses - 2/2

- Single analysis for resonant and nonresonant production
 - Signal extraction on $m_{bb}/m_{\gamma\gamma}$

Exclusive phase spaces

Tight photon selections reject all events from the other analyses

Only analysis to use 2 leptons, no overlap with others. $\tau \tau \rightarrow 2\ell + \nu s$ events are considered but not used in the bb $\tau \tau$ analysis

bbbb events suppressed by small τ mistag probability. No overlap with bbWW because of extra lepton veto.

A few $bb\tau\tau$ events pass the bbbb preselections, but are rejected by the MVA discriminants and requiring 4 b-tagged jets. No overlap with bbWW because of extra lepton veto.

Absence of phase space overlap is checked with data event lists selected by the analyses

Making sure that analyses are orthogonal is an important step for a combined result

An example: the HH \rightarrow bbbb case

2 large area b jets

Resonant fully merged

bbbb orthogonalisation particularly challenging because of several analyses involved Harmonising the methods and analysis strategy will help to make combination easier

Luca Cadamuro (UF)

1 large area + 2 standard b jets

Resonant semi merged

Simple orthogonalisation by vetoing fully merged events in semi merged analysis

Cannot switch of analysis for nonresonant signals Veto events accepted by the resolved search in the (semi) merged analysis

4 standard b jets

Nonresonant resolved

Systematic uncertainties

Highest impact uncertainties for the SM HH signal:

 τ energy scale

bbbb high BDT score bins $m_{\gamma\gamma}$ signal shape

Combined result is statistically dominated: 3.5% effect on the limits from syst. uncertainties

- Luminosity: fully correlated for all channels
- **Trigger**: assumed uncorrelated
- **Object reconstruction, efficiency and scale:** correlated across the same objects
 - b tag uncertainties play a special role: split in heavy and light flavour sources jet uncertainties split in 27 uncorrelated sources to avoid artificial constraints
- **Bin-by-bin templated shapes**: uncorrelated
- **Analysis specific** (lineshapes, control regions, ...) : uncorrelated
- **Background modelling** (QCD, DY): assumed uncorrelated because of different methods used
- Theory (bkg): correlated for the same processes across channels
- Theory (HH): correlated for all channels

Luca Cadamuro (UF)

- Most sensitive result to date on SM HH production
- Sensitivity improved by a factor of ~4 over Run I combined result
- A hierarchy in the sensitivity can be observed...
 - $\Box \quad bb\gamma\gamma \rightarrow bb\tau\tau \rightarrow bbbb \rightarrow bbVV$
 - ... but **no "golden channel"**: important contribution from all analyses to the combined result
 - even more evident in the exploration of BSM HH production

Results : SM signal

Combined limit on σ / σ_{SM} Observed: 22.2 Expected: 12.8

Results : resonant production

CMS-PAS-HIG-17-030

- Limits also set for spin 2 resonances
- Assumes narrow resonance width
- Basic assumption: SM BR for H decays

The combination takes advantage of channel complementarity to improve the sensitivity to resonances from 250 GeV to 3 TeV

Combination of HH searches with the CMS experiment

- Shape of the upper limit directly related to the interference between the box and triangle diagrams
 - changes in the m_{HH} spectrum \implies changes in the analyses acceptance and background discrimination
 - λ_{HHH} values smaller than SM prediction are easier to probe : we may be sure that the Higgs boson self couples before observing an HH signal!

CMS-PAS-HIG-17-030 Results: anomalous trilinear coupling

Constraint on $k_{\lambda} = \lambda_{HHH} / \lambda_{HHH}^{SM}$ Observed : $-11.8 < k_{\lambda} < 18.8$ Expected : $-7.1 < k_{\lambda} < 13.6$

Results : BSM nonresonant production CMS-PAS-HIG-17-030

Luca Cadamuro (UF)

A few personal considerations

- Going beyond the SM signal is crucial to fully explore the physics behind HH production
 - shape benchmarks : useful guidance but not fully general. How to make HH results widely useful for the theory community?
 - would differential upper limits in m_{HH} (from signals in exclusive) m_{HH} bins at gen level injected into the analyses) be useful and usable?
- Not trivial to treat the SM Higgs backgrounds in the exploration of EFT anomalous couplings
 - \Rightarrow suppress single H processes as much as possible
 - \Rightarrow combination with single Higgs searches
- Analyses statistically limited \Rightarrow ATLAS and CMS combination to fully exploit the LHC potential
 - many subtle differences in signal modelling, analysis strategy, etc. that we need to start understanding
 - important to be aligned on the set of results

Luca Cadamuro (UF)

SM + BSM scalar mixing in models with enhanced charm coupling. Clearly not a resonant signal, but not covered by the shape benchmarks.

Concusions

- Combination of HH analyses is necessary to improve the CMS sensitivity to HH production similar sensitivity to SM signal from many analyses
- - complementary coverage of BSM parameter space
- Checks of the phase space overlap and proper treatment of systematic uncertainties are a necessary step for a reliable combined result
- The combined limit is to date the most sensitive result to SM HH production combined limits on resonant production
 - combined limits on anomalous trilinear coupling
 - EFT parameter space explored using shape benchmark signals
- The combined results are statistically limited and expected to improve with larger datasets also a good motivation towards and ATLAS and CMS combination
- The trilinear coupling is elusive \Rightarrow a combination with single Higgs measurement (λ_{HHH} constraints from NLO effects) would be a further step in our understanding
- Our future capability to observe HH will rely on a phenomenologically rich program of experimental searches that explore and combine many final states

Luca Cadamuro (UF)

Additional material

Benchmark shapes

- Each benchmark shape corresponds to a specific choice of the 5 EFT couplings
- The choice does not have a special physical meaning: it is only meant to represent a shape, not a special point in the EFT parameter space
