

# Experiments at LHC and Bulgarian Participation

## OUTLINE

Short introduction to the physics goals of LHC

Design and preliminary results of the experiments:

Bulgarian Participation at LHC experiments - CMS

We are trying to solve some of the main puzzles of nature  
What is the origin of mass

- What could be the dark matter that keeps together the clusters of galaxies
- Why the main interactions are so different in strength
  - Why gravity is not included so far in our picture
  - How many are really the dimensions of our world

The answer to some of these questions is probably hidden in the so far unexplored TeV region

**CMS** Compact Muon Solenoid

**ATLAS** A Toroidal LHC Apparatus

**LHCb** LHC**b**eauty experiment

**ALICE** - A Large Ion Collider Experiment

Precision (1%) measurement of total cross section (and more) **TOTEM**  
Study of forward  $n^0$  production **LHCf**  
Search for magnetic monopoles **MoEDAL**

## Leptons

## Strong

## Electromagnetic

## Quarks

## Gravitational

## Weak

The Standard Model is still among the most successful theories tested so far (accuracy  $<10^{-4}$  in hundreds of measurements up to an impressive  $10^{-12}$  in electron  $g-2$ ).

LEP, CDF&D0: we really understand physics up to  $\sim 100\text{GeV}$ .

It is sort of a monument of the physics of the 20<sup>th</sup> century: it brings together quantum mechanics and special relativity. It is simple and elegant: it explains a huge amount of data using only 19 parameters.

**Why we are not happy with it ?**

The bare SM could be consistent with massless particles **but** matter particles range from almost 0 to about  $170\text{GeV}$  while force particles range from 0 to about  $90\text{GeV}$ .

How can it be that a massless photon can carry the same electroweak interaction of a  $80\text{-}90\text{ GeV}$  W or Z?

The simplest solution (Higgs, Kibble, Brout, Englert 1960's)

**All particles are massless !! A new scalar field pervades the universe.**

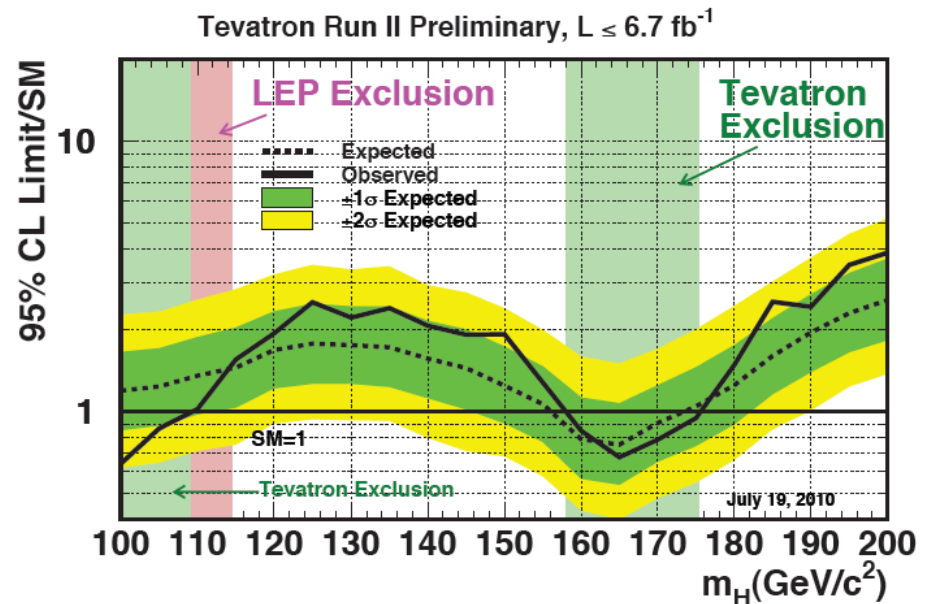

**Particles interacting with this field acquire mass: the stronger the interaction the larger the mass.**

## The Higgs mechanism

### How heavy is the Higgs: the TeV scale

Today the Higgs is directly excluded in a small region of mass.  
To be sure to be able to catch it (if it does exist) a safe attitude is to explore the entire region between 100 and 1000 GeV.

ICHEP 2010

The theory is elegant, coherent, and consistent with all observations.....  
but nobody has been able so far to identify this new particle.

Unfortunately the theory does not constrain significantly the mass of the boson.

$M_H$  can be considered as a free parameter.

The Higgs boson can live anywhere between a few 10 GeV and many 100 GeV.

**A definitive answer can come only from careful experiments.**

Electroweak constraints

$$\ln M_H \propto \Delta M_W \propto M_t^2$$

# Experiments at LHC and Bulgarian Participation

The unification of all forces of nature.  
The dream of all physicists, the “mother” of all challenges

**But to verify them we need to discover the Higgs, the supersymmetric particles and the very massive particles predicted by extradimensional theories (100GeV to several TeV)**

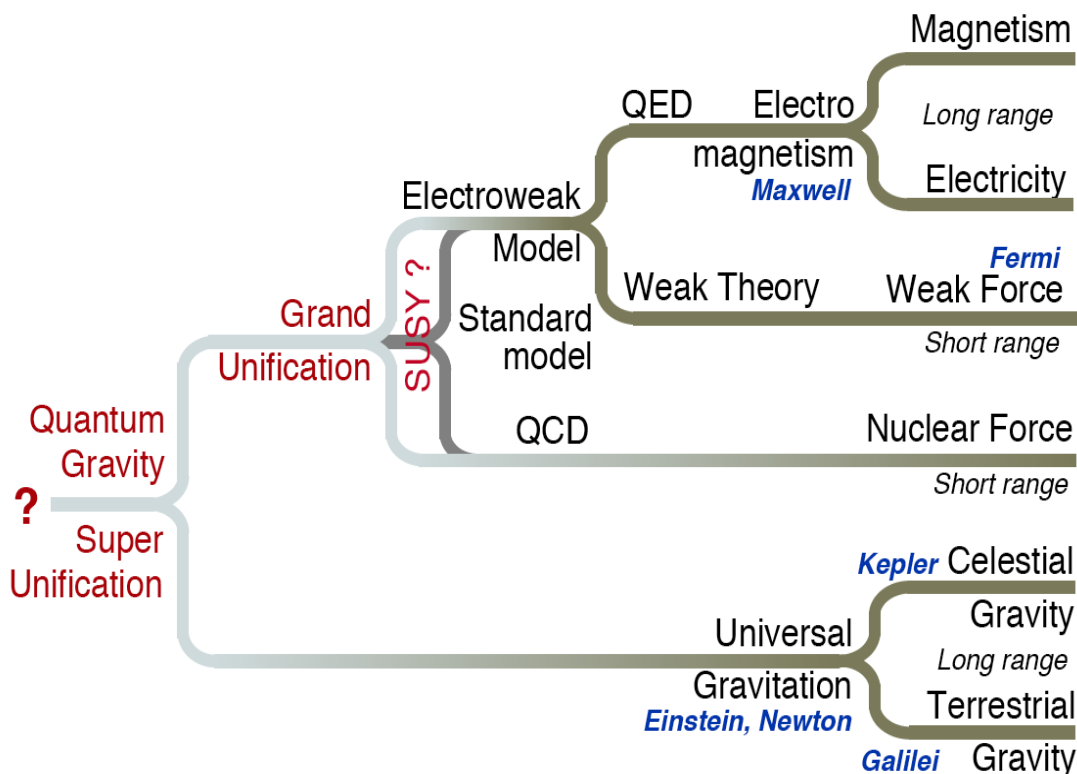

All these particles have escaped detection so far.  
This could be due to the fact that:

- a) The theories are wrong or
- b) We have not been able to produce them so far because the energy of previous accelerators was not high enough.

We should remember that to produce a mass  $m$  we need an energy  $E=mc^2$ . So far the modern experiments have produced and studied particles up to masses  $\sim 100\text{GeV}$ .

All these are elegant theories

**Let's try to produce and study masses  $\sim \text{TeV}$**

# Experiments at LHC and Bulgarian Participation

## Theory and Experiments

- Exp: Particles have masses: .....why ?
- Theo: Mass is given by the interaction with the Higgs field
- Exp: Find the Higgs Boson
  
- Exp: There are 3 Forces: .....why ?
- Theo: Super Symmetry unifies the Forces
- Exp: Find the signals of Super Symmetry

## Basic detector

New physics will be detected by the production of **NEW PARTICLES**. These particles will disintegrate in very short time ( $10^{-24}$  s) and we will detect their decay products. The particles that we will detect are particles with “long-life-time”. The LHC detectors are designed to record the largest possible amount of information about these final state particles.

## What is needed for TeV physics?

**Selection of 1 event in 10,000,000,000,000**

# Experiments at LHC and Bulgarian Participation

## Typical elements of a collider detector

Materials with high number of protons + Active material

Hermetic calorimetry  
• Missing Et measurements

**Electromagnetic and Hadron calorimeters**

- Particle identification (e,  $\gamma$  Jets, Missing E<sub>t</sub>)
- Energy measurement

Heavy materials

**Muon detector**

- $\mu$  identification

Light materials

**Central detector**

- Tracking, p<sub>t</sub>, MIP
- Em. shower position
- Topology
- Vertex

Heavy materials (Iron or Copper + Active material)

## Overall view of the LHC experiments.

Each layer identifies and enables the measurement of the momentum or energy of the particles produced in a collision

**pseudorapidity**,  $\eta$ , is a commonly used spatial coordinate describing the angle of a particle relative to the beam axis.

$$\eta = -\ln \left[ \tan \left( \frac{\theta}{2} \right) \right],$$

$$\begin{aligned} \theta = 90^\circ &\rightarrow \eta = 0 \\ \theta = 10^\circ &\rightarrow \eta \approx 2.4 \\ \theta = 170^\circ &\rightarrow \eta \approx -2.4 \end{aligned}$$

## Collider Luminosity

$$R = \mathcal{L} \sigma_{\text{int}}.$$

$$\mathcal{L} = \frac{N_b^2 n_b f_{\text{rev}} \gamma_r}{4\pi \epsilon_n \beta^*} F$$

$N_b$  = number of proton per bunch  
 $n_b$  = number of bunches

$f_{\text{rev}}$  = revolution frequency  
 $F$  = crossing angle factor

Rms transverse beam size =  $\sqrt{\epsilon_n \beta^*}$   
 $\epsilon_n$  = normalized transverse emittance  
 $\beta^*$  = optics at beam crossing (m)  
 $\gamma_r$  = relativistic factor

Luminosity is measured in units of  $\text{length}^{-2} * \text{time}^{-1}$   
 Typical collider values are in the range of  $10^{30 \pm \text{units}} \text{ cm}^{-2} \text{ sec}^{-1}$

Table 1.1: The machine parameters relevant for the LHC detectors.

# Experiments at LHC and Bulgarian Participation

For Higgs signals in CMS we need to be patient. Very likely 14 TeV will be needed

Low  $M_H < 150$  GeV

Medium  $130 < M_H < 500$  GeV

High  $M_H > \sim 500$  GeV

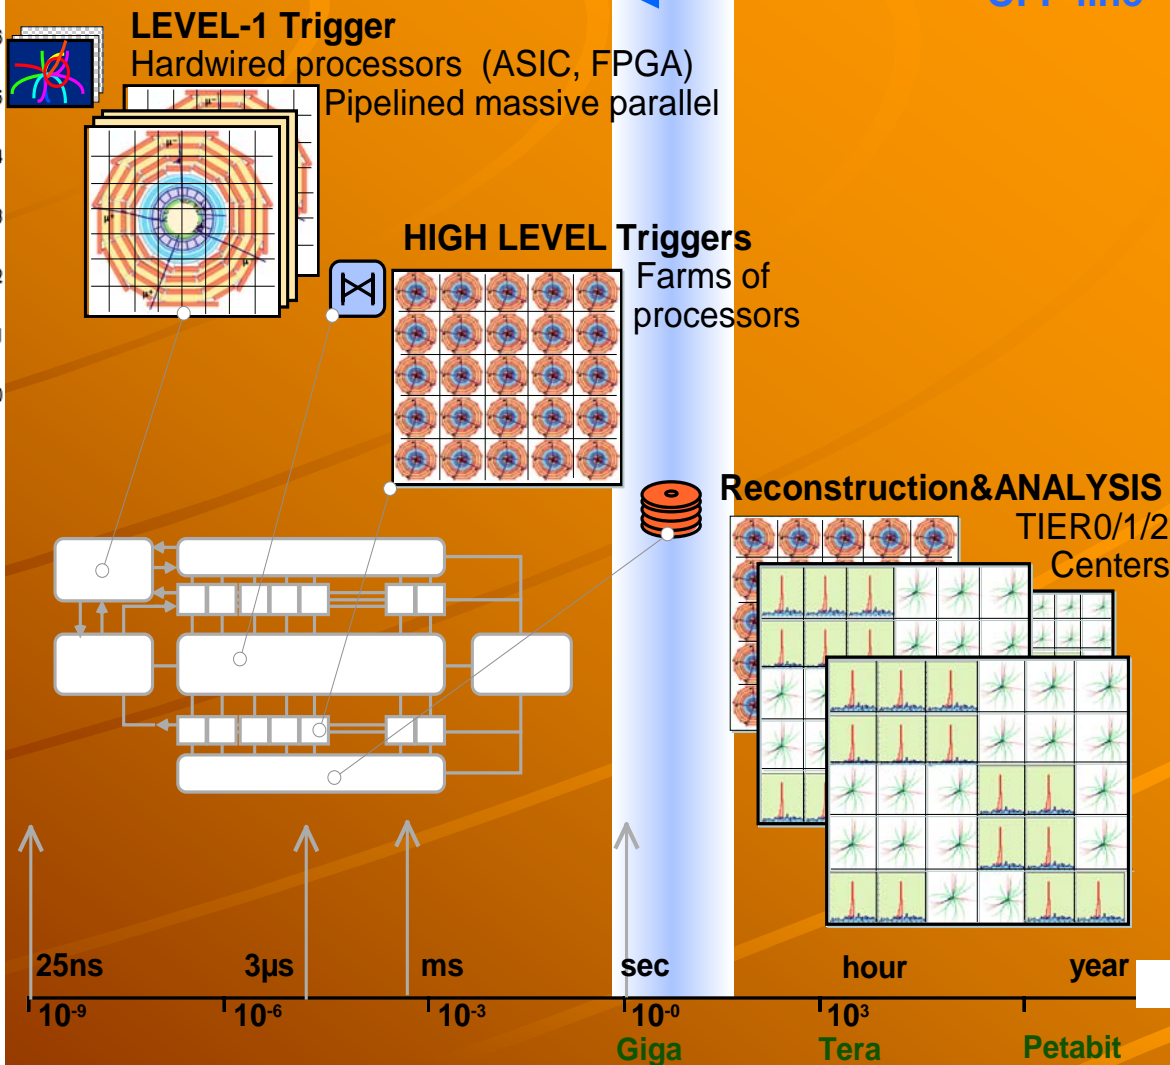

# A high granularity device is needed to reconstruct hundreds of tracks per event

ON-line

OFF-line

## Imagine CMS as a huge and very fast digital camera

The interesting events are very rare. An incredibly high number of collisions is needed to be able to identify particles like the Higgs boson.

CMS can be compared to a huge digital camera of 100Megapixel which can take **40 millions pictures per second**.

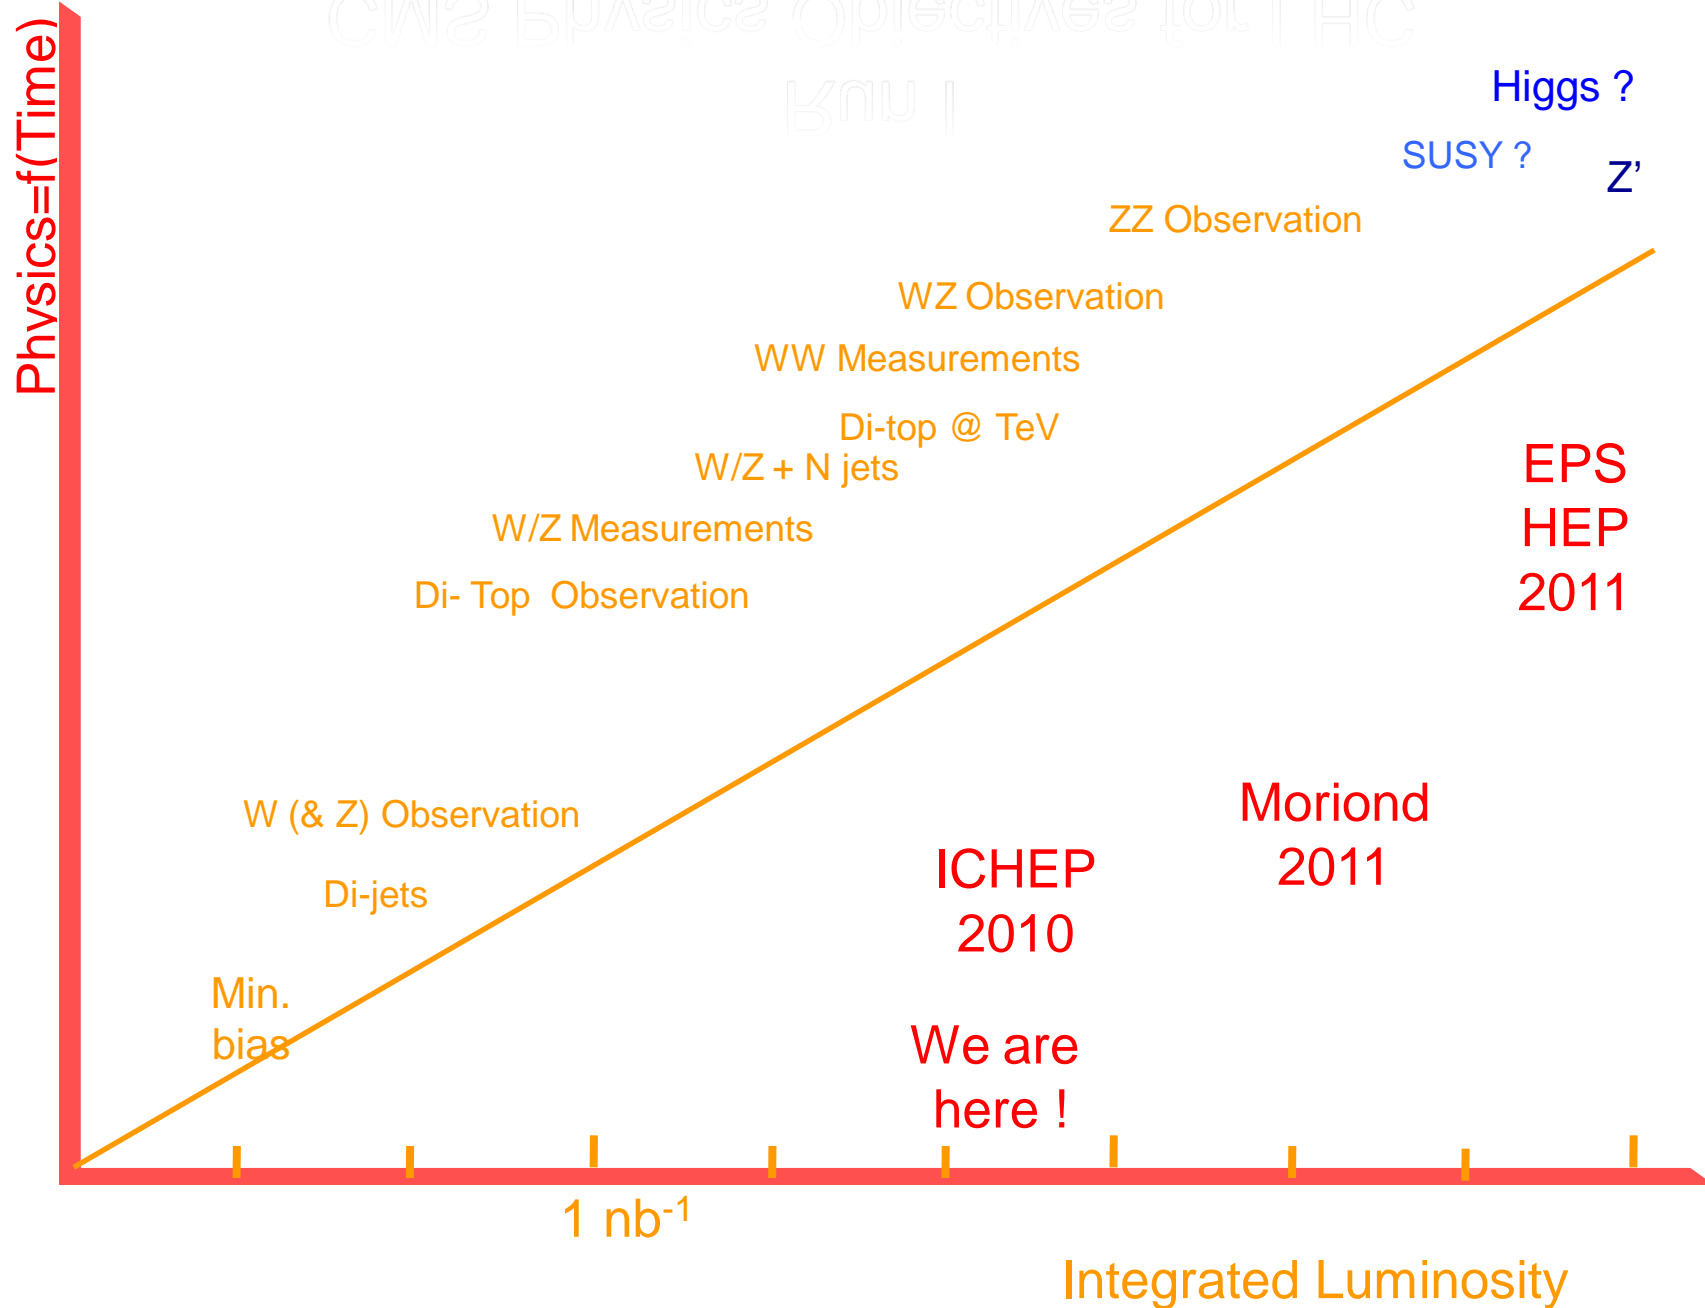

The pictures are quickly scanned and **after a first look, that takes about 3 millionths of a second, 100.000 pictures are preliminary selected: L1 Trigger**

In about 50-100 milliseconds a more detailed scan of the pre-selected pictures will discard most of the 100.000 pictures (**HLT: High Level Trigger**) to **record permanently on disk the 100-400 really promising**.

The operation will be repeated every second for the whole data taking period:  
**~ several PB of data/year**

**Grid Computing** bringing together many powerful computing centers will be needed to store/re-reconstruct/analyze the data

# CMS Physics Objectives for LHC Run 1

About  $3.6\text{pb}^{-1}$  delivered by LHC and  $\sim 3.3\text{pb}^{-1}$  of data collected by CMS. Overall data taking efficiency  $>92\%$ .

## Here is the Compact Muon Solenoid

Good performance of CMS in coping with 4 orders of magnitude increase in instantaneous luminosity. Since ICHEP we have recorded another  $3.0\text{pb}^{-1}$  of data:  $2.9\text{pb}^{-1}$  validated for physics in total (86% of the recorded data)

# Extraction of the $W^\pm (Z^0) \rightarrow \mu^\pm \mu^\mp$ ( $|\eta| < 2$ ) yield signal

Trigger HLT path:  $\mu + X(p_T > 9 \text{ GeV}/c)$   $|\eta| < 2$ .  
 Good quality muon track (hits in pixels, strip tracker, muon system and  $\chi^2/\text{dof} < 10$ ). For the W: relative isolation  $\leq 0.15$  in a cone of  $\Delta R < 0.3$  around the muon. For the Z: looser quality criteria on the second muon, opposite charge and  $|\eta| < 2.4$ ; both muons isolated,  $p_T > 20 \text{ GeV}$  and invariant mass  $60 < m_{\text{mm}} < 120 \text{ GeV}/c^2$ . Simultaneous fits to backgrounds and signal contributions. QCD background shapes obtained using data. EWK background shapes and signal from MonteCarlo.

# Results

**Notice: ~all major components of the measurements (efficiency, background, systematic errors etc) are carefully evaluated using data driven methods.**

# Dileptonic channels: $ee, \mu\mu, e\mu + X$

- Triggers:  $\mu+X$  ( $p_T > 9$  GeV/c) or  $e/\gamma+X$  ( $E_T > 15$  GeV)
- 2 isolated, prompt, oppositely charged leptons ( $l = e, \mu$ ) of good quality
  - $p_T(l) > 20$  GeV/c
  - $|\eta_\mu| < 2.5$ ,  $|\eta_e| < 2.4$
  - Relative isolation  $< 15\%$ .
- Missing transverse energy (MET)
  - using calorimeter $\oplus$ tracking
  - MET  $> 30$  (20) GeV (in  $e\mu+X$ )
- Z-boson veto:
  - $76 < M_{ee, \mu\mu} < 106$  GeV/c<sup>2</sup>
- Count additional jets:
  - anti- $k_T$  jets,  $R = 0.5$
  - using calorimeter $\oplus$ tracking info
  - $|\eta| < 2.4$ ,  $p_T > 30$  GeV/c
  - $\geq 2$  jets typical for  $t\bar{t}$

# $\mu\mu$ +Jets Candidate Event

**Event passes all cuts of full selection**

- 2 muons with opposite charge
- 2 jets, both w/ good/clear *b*-tags (and secondary vertices!)
- significant MET (>50 GeV)

$$m(\mu\mu) = 26 \text{ GeV}/c^2$$

Preliminarily reconstr. mass is in the range 160–220  $\text{GeV}/c^2$  (consistent with  $m_{\text{top}}$ )

Using the full statistics currently validated ( $0.84\text{pb}^{-1}$ ) and **requiring at least 1 jet b-tagged** (secondary vertex tagger with  $\geq 2$  tracks; high efficiency with  $\sim 1\%$  fake rate)

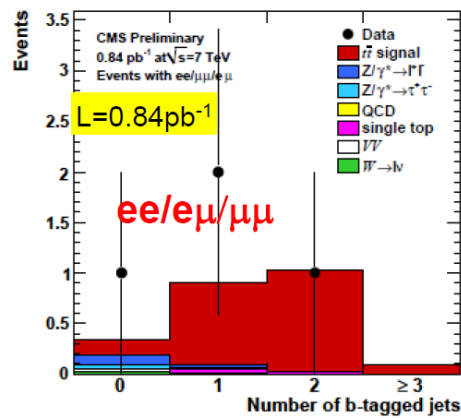

For  $N(\text{jets}) \geq 3$  we count **30 signal candidates over a predicted background of 5.3**

t-tbar events are observed in CMS at a rate consistent with NLO cross section, considering experimental (JES, b-tagging) and theoretical (scale, PDF, HF modelling, ...) uncertainties.

## Di-lepton+jets top selection

- Full selection applied: Z-bosonVeto,  $|M(\text{ll})-M(\text{Z})| > 15 \text{ GeV}$
- MET > 30 (20) GeV in ee,  $\mu\mu$ , ( $e\mu$ );  $N(\text{jets}) \geq 2$

**4 ttbar candidates (1 $\mu\mu$ , 1ee, 2 $\mu\mu$ ) over a negligible background. Top signal at LHC established. First cross sections will come soon!**

# High multiplicity events at 7 TeV

Results for intermediate  $p_T$ : 1-3 GeV/c

Minimum Bias  
no cut on multiplicity

High multiplicity data set  
and  $N > 110$

(b) MinBias,  $1.0 \text{ GeV}/c < p_T < 3.0 \text{ GeV}/c$

(d)  $N > 110$ ,  $1.0 \text{ GeV}/c < p_T < 3.0 \text{ GeV}/c$

New “ridge-like” structure extending to large  $\Delta\eta$  at  $\Delta\phi \sim 0$

The new feature has appeared in our analysis around middle of July in the hottest days of the preparation for ICHEP. We have immediately set-up an independent analysis (control group) and organized a full set of tests and cross-checks to kill the effect.

We didn't succeed to kill it.

We have therefore submitted the paper to expose our findings to the scrutiny of the scientific community at large.

Since there are a number of potential explanations, today's presentation is focussed on the experimental evidence in the interest of fostering a broader discussion on the subject.

We are planning many additional studies aimed at producing a better understanding of the dynamics of the effect. The incoming Heavy Ion run will be an additional important test bench.

The new feature is clearly seen for large rapidity differences  $2 < |\Delta\eta| < 4.8$  in events with  $N \sim 90$  or higher. The enhancement is most evident in the intermediate  $p_T$  range  $1 < p_T < 3 \text{ GeV}/c$ .

This is the first observation of such a long-range, near-side feature in two-particle correlation functions in pp or p-pbar collisions.

# Experiments at LHC and Bulgarian Participation

The “golden” channel  $H \rightarrow ZZ^* \rightarrow 4l$

$H \rightarrow \gamma\gamma$  : to observe a signal peak on top of a huge background need

- energy/mass resolution  $\sim 1\%$
- rejection of  $\pi^0 \rightarrow \gamma\gamma$  faking single  $\gamma$

- Higgs discovery channel in the mass range from 130-500 GeV with 30fb<sup>-1</sup>
- A 150 GeV Higgs could be discovered with 5 fb<sup>-1</sup>

# Experiments at LHC and Bulgarian Participation

**ALICE** - A Large Ion Collider Experiment

**LHCb** LHCbeauty experiment

**ATLAS**

# Experiments at LHC and Bulgarian Participation

The ALICE Experiment is going in search of answers to fundamental questions, using the extraordinary tools provided by the LHC:

What happens to matter when it is heated to 100,000 times the temperature at the centre of the Sun ?

Why do protons and neutrons weigh 100 times more than the quarks they are made of ?

Can the quarks inside the protons and neutrons be freed ?

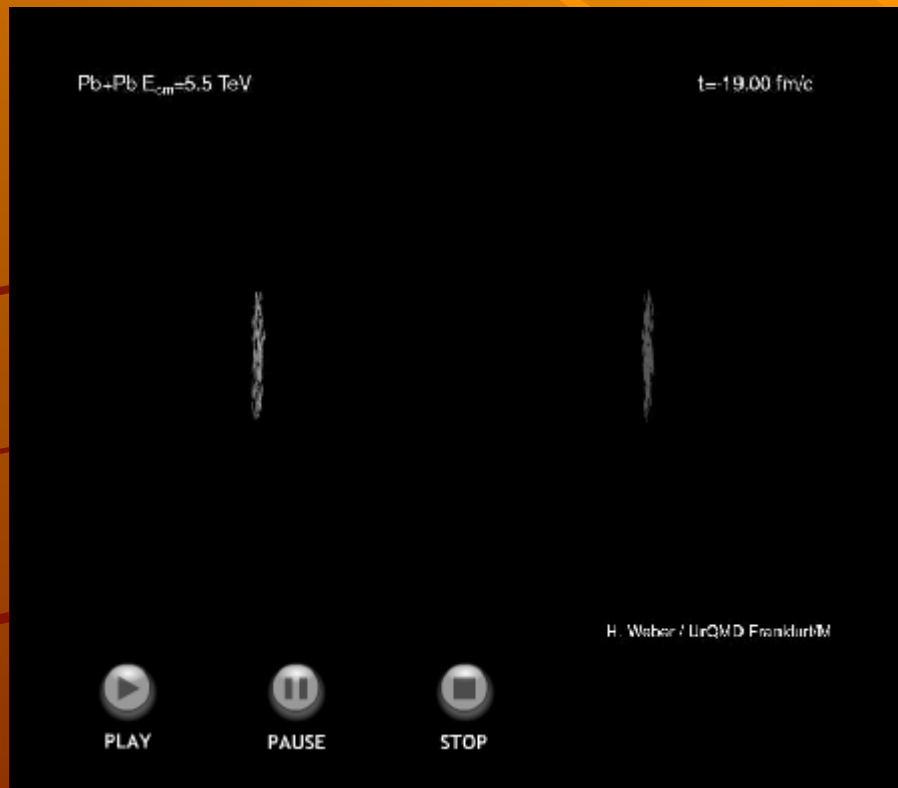

LHC Pb design luminosity  $L = 10^{27} \text{ cm}^{-2} \text{ s}^{-1}$

$E = 2.96 \text{ TeV}$ , No of bunches = 592,

No of particles per bunch =  $7 \times 10^7$

The final **ALICE** detector configuration[3], consists of a central detector system, covering about two units of rapidity, embedded in a very large solenoid with a field of **0.5T**, a one-arm **forward muon spectrometer** and **forward multiplicity and centrality detectors**.

From the inside out, the barrel contains an **Inner Tracking System** (ITS) of six layers of high-resolution silicon pixel (SPD), drift (SDD), and strip (SSD) detectors, a **cylindrical Time-Projection Chamber** (TPC), three particle identification arrays of **Time-of-Flight** (TOF), **Ring Imaging Cherenkov** (HMPID) and **Transition Radiation** (TRD) detectors, and two **electromagnetic calorimeters** (PHOS and EMCAL). All detectors except HMPID, PHOS, and EMCAL cover the full azimuth. The TPC and the ITS contribute to the particle identification via the measurement of specific energy loss. An array of scintillators (ACORDE) on top of the L3 magnet is used to trigger on cosmic rays.

## Free Quarks and Gluons

The current theory of the strong interaction (called Quantum Chromo-Dynamics) predicts that at very high temperatures and very high densities, quarks and gluons should no longer be confined inside composite particles. Instead they should exist freely in a new state of matter known as quark-gluon plasma.

Such a transition should occur when the temperature exceeds a critical value estimated to be around 2 000 billion degrees... about 100 000 times hotter than the core of the Sun! Such temperatures have not existed in Nature since the birth of the Universe. We believe that for a few millionths of a second after the Big Bang the temperature was indeed above the critical value, and the entire Universe was in a quark-gluon plasma state.

The two heavy nuclei approach each other at a speed close to that of light. According to Einstein's theory of relativity, they appear as very thin discs.

The nuclei collide and the extreme temperature releases the quarks (red, blue and green) and the gluons.

Quarks and gluons collide with each other creating a thermally equilibrated environment: the quark-gluon plasma.

# 1. Quark Matter

# 2. QGP

**LHCb:** dedicated b-physics experiment at LHC that will search for NP beyond the SM through the study of very rare decays of b-flavoured (and c) hadrons and precision measurements of CP-violating observables

Enormous progress in recent years from the B factories and Tevatron, far beyond expectations.

Clear demonstration of the SM CKM mechanism as dominant source of CP violation.

## Advantages of beauty physics at hadron colliders:

High value of beauty cross section expected at 14 TeV:  $\sigma_{bb} \sim 0.5 \text{ mb}$

( $e^+e^-$  cross section at  $Y(4s)$  is 1 nb)  $\sigma_{cc} \sim 3.6 \text{ mb}$

Access to all b-hadrons:  $B^\pm$ ,  $B^0$ ,  $B_s$ ,  $B_c$ , b baryons

In particular can study the  $B_s$  (bs) system, not studied at the B factories, but measured by CDF/D0.

The challenges:

Rate of background events:  $\sigma_{inel} \sim 80 \text{ mb}$

→ Trigger is essential!

→ Multiplicity of tracks ( $\sim 30$  tracks per rapidity unit)

## Baryogenesis

*Big Bang* ( $\sim 14$  billion years ago)  $\rightarrow$  matter and antimatter equally produced; followed by annihilation  $\rightarrow n_{\text{baryon/ng}} \sim 10^{-10}$

*Why didn't all the matter annihilate (luckily for us)?*

*No evidence found for an "antimatter world" elsewhere in the Universe*

*One of the requirements to produce an asymmetric final state (our world) from a symmetric matter/antimatter initial state (the Big Bang) is that CP symmetry must be violated [Sakharov, 1967]*

*CP is violated in the Standard Model, through the weak mixing of quarks. For CP violation to occur there must be at least 3 generations of quarks.*

*So problem of baryogenesis may be connected to why three generations exist, even though all normal matter is made up from the first ( $u$ ,  $d$ ,  $e$ ,  $\nu_e$ )*

*However, the CP violation in the SM is not sufficient for baryogenesis*

*Other sources of CP violation expected  $\rightarrow$  good field to search for new physics*

Detector designed to maximize b acceptance  
(against  $\cos\theta$ )

Forward spectrometer  $1.9 < \eta < 4.9$

b-hadrons produced at low angle

Single arm OK as b quarks are produced in same fwd or backward cone

vertices and momenta reconstruction  
effective particle identification ( $\pi$ ,  $K$ ,  $\mu$ ,  $e$ ,  $\gamma$ )  
triggers

7 December 1998

### Full Size Pre-production Prototypes of HCAL

Pre-production prototypes of a barrel wedge and endcap sector have been manufactured in industry. The barrel wedge was manufactured by Belguena in Spain using brass plates procured in Bulgaria under the responsibility of HCAL-US groups. The endcap sector was manufactured by MZOR in Belarus using brass plates procured in Bulgaria and St. Petersburg under the responsibility of HCAL-RDMS groups. The scintillators trays have been installed in the prototypes and the HCAL system will be tested in 1999.

Substantial Rates for  $E_\mu > 10$  GeV

| $N_{HIT} \geq 1$ | Rate [Hz] |
|------------------|-----------|
| CMS tot          | ~ 1800    |
| Muon only        | ~ 1800    |
| calorimeter      | ~ 700     |
| tracker          | ~ 60      |

- RPC efficiency and cluster size are estimated from data using DT/CSC segment extrapolations or reconstructed muons
  - Data collected are now enough to produce efficiency table chamber-by-chamber and new condition DB tags should be available soon
  - Cluster size is at the moment modeled as a function of the local impact point on the strip. Present data will be used to model it as function of slope as well
- Dead and masked strips are monitored run by run but still not in DB. All the software infrastructure is ready to handle them.

**RPC – high rechit efficiency (~94%) for all chambers in both barrel and endcap**

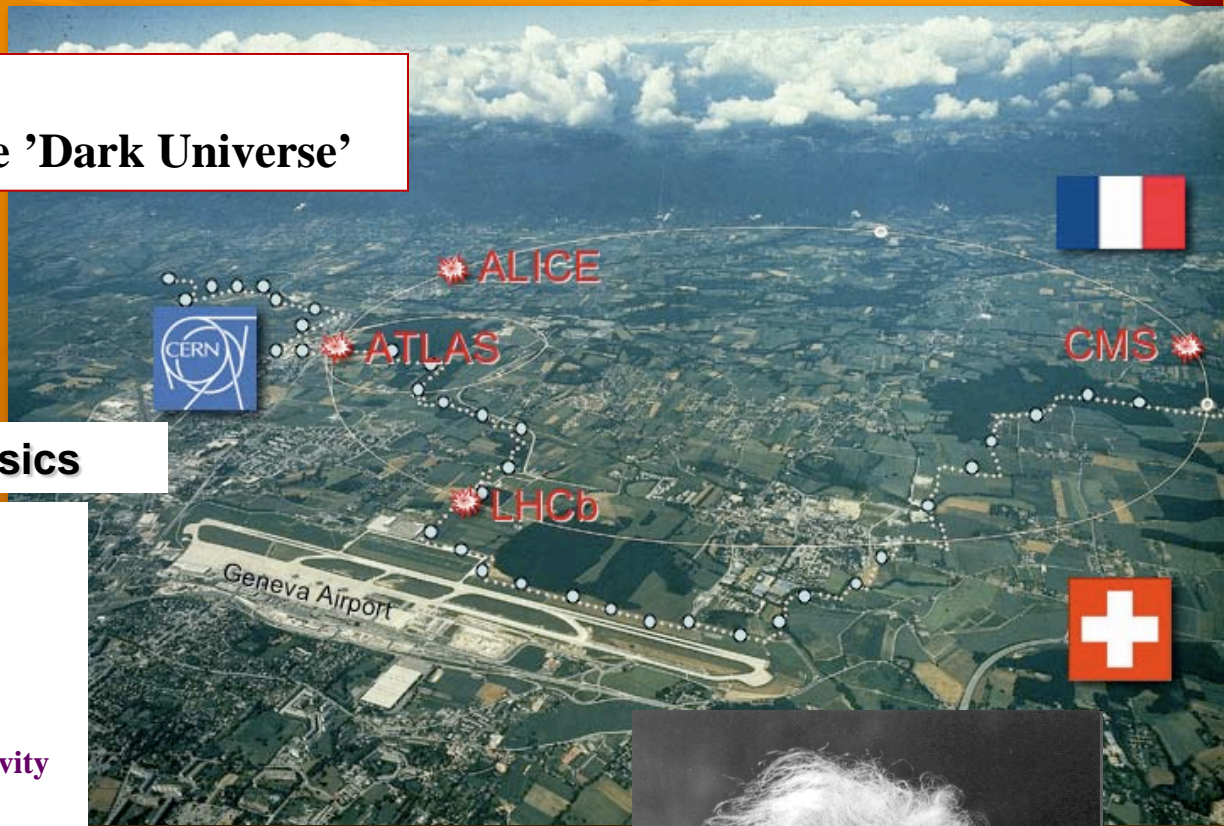

RPC hit-time relative to L1A

## RPC hit synchronization

- excellent time synchronization achieved (>99% of RB+RE has  $\Delta BX=0$ )
- Some fine tuning still possible (~1-2 ns) for a fraction of the LB at  $BX=0$

With the Large Hadron Collider  
at the Terascale now entering the 'Dark Universe'

## Key Questions of Particle Physics

Origin of mass/matter

Origin of electroweak symmetry breaking

Unification of forces

Fundamental symmetry of forces and matter

Unification of quantum physics and general relativity

Number of space/time dimensions

What is dark matter

What is dark energy

*The most incomprehensible thing about the world is  
that it is at all comprehensible.*

# Today's Universe: very old and very cold

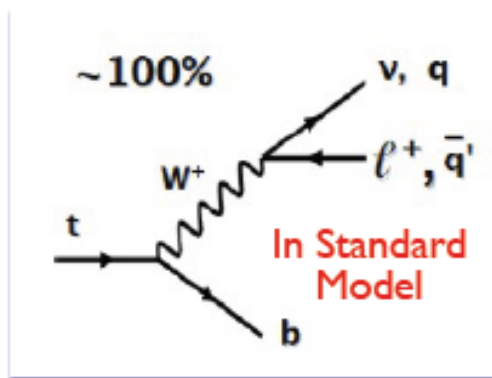

Big Bang

# Top quark production and decay

- Main mechanism: pair production via strong interaction
  - ▶ Tevatron:  $q\bar{q}$  (85%),  $\sigma=7.46$  pb
  - ▶ LHC@7 TeV:  $gg$  (~90%),  $\sigma=160.8$  pb
  - ▶ theoretical uncertainty ~9%

NNLO<sub>approx</sub> for  $m_t = 172.5$  GeV  
PRD 80, 054009 (2009)

W decay mode defines top pair final state

>5 fb<sup>-1</sup> of data, ~3,000 b-tagged top candidates per Tevatron experiment

## Experiments at LHC and Bulgarian Participation

$m_e$  Electron mass 511 keV

$m_\mu$  Muon mass 105.7 MeV

$m_\tau$  Tau mass 1.78 GeV

$m_u$  Up quark mass 1.9 MeV

$m_d$  Down quark mass 4.4 MeV

$m_s$  Strange quark mass 87 MeV

$m_c$  Charm quark mass 1.32 GeV

$m_b$  Bottom quark mass 4.24 GeV

$m_t$  Top quark mass 172.7 GeV

$\theta_{12}$  CKM 12-mixing angle  $13.1^\circ$

$\theta_{23}$  CKM 23-mixing angle  $2.4^\circ$

$\theta_{13}$  CKM 13-mixing angle  $0.2^\circ$

$\delta$  CKM CP-violating Phase 0.995

$g_1$  U(1) gauge coupling 0.357

$g_2$  SU(2) gauge coupling 0.652

$g_3$  SU(3) gauge coupling 1.221

$\theta_{\text{QCD}}$  QCD vacuum angle  $\sim 0$

$\mu$  Higgs quadratic coupling Unknown

$\lambda$  Higgs self-coupling strength Unknown

# The benchmark reactions

Lep 190

$H \rightarrow \gamma\gamma$  ( $WH \rightarrow \gamma\gamma l$ ) ( $t\bar{t}H \rightarrow \gamma\gamma l$ )

$H \rightarrow ZZ^* \rightarrow 4l$

$H \rightarrow ZZ \rightarrow 4l$

$H \rightarrow ZZ \rightarrow 2\nu + 2\mu$  or  $2e$

$H \rightarrow WW$  or  $ZZjj \rightarrow 2ljj$

# Experiments at LHC and Bulgarian Participation

**Event rate =  $L\sigma Br$**

e.g.  $H \sim 0.8 \text{ TeV}$ ;  $H \rightarrow ZZ \rightarrow 4l$

Events/year  $\geq 10 \Rightarrow (10/10^7) \times 1/(10^{-37} \cdot 10^{-3}) =$

**$L \sim 10^{34} \text{ cm}^{-2} \text{ s}^{-1}$**

**$M_H \sim 1000 \text{ GeV}$**

$E_W \geq 500 \text{ GeV}$ ;  $E_q \geq 1000 \text{ GeV}$  (1 TeV);  **$E_p \geq 6000 \text{ GeV}$**  (6 TeV)

**$\rightarrow$  Proton Proton Collider with  $E_p \geq 6-7 \text{ TeV}$**

**$\rightarrow L \sim 10^{33}-10^{34} \text{ cm}^{-2} \text{ s}^{-1}$**

## 5 $\sigma$ Higgs Signals (statistical errors only)

# Muons

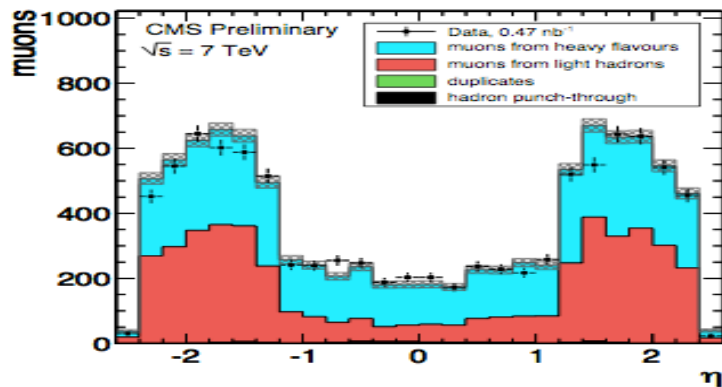

Muons identification efficiencies and kinematic variables have been studied in detail using minimum bias events and dimuon resonances.

(a)

(b)

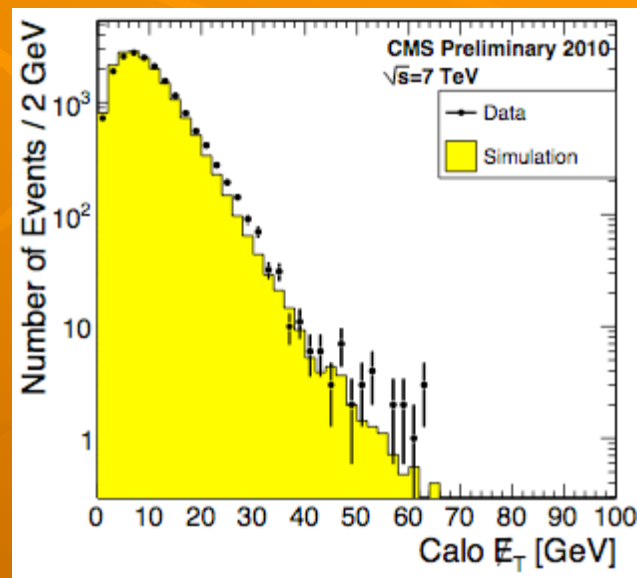

Distributions dominated by light hadron decay (red); excellent agreement with MC prediction including heavy flavor decays (blue); small fraction of punch-through (black) and fakes (green).

- $\pi^0$  peak reconstructed offline 200 seconds into 7 TeV run

## Calorimetry: Missing $E_T$

Calibration triggers have access to full L1 rate, and they output small fraction of event

“Transverse Momentum and Pseudorapidity Distributions of Charged Hadrons in pp Collisions at  $\sqrt{s}=7\text{TeV}$ ”, *Phys. Rev. Lett.* 105, 2010.

Jets reconstructed with the anti- $k_T$   $R=0.5$  algorithm

Dijet selection : Jet  $P_T > 25 \text{ GeV}$ ,  $\Delta\phi > 2.1$ ,  $|\eta| < 3$

Loose ID cuts on number of components and neutral/charged energy fraction

## Calorimetric di-jet events
