Identified particle production in inelastic pp events with the ATLAS detector

Thursday 22 July 2010 12:00 (12 minutes)

Studies of the long-lived resonances K_s and Λ , reconstructed in inelastic collisions at 900 GeV and 7 TeV using a minimum bias trigger, have been performed using the ATLAS inner tracking detector. The spectra for these resonances are measured as a function of their transverse momentum and rapidity, and compared with Monte Carlo models. The ratio of anti- Λ to Λ production is evaluated, providing further tests of Monte Carlo models. The results are corrected for all detector effects, to simplify comparisons to models and other experiments.
