

Statistical Issues & Methods in Neutrinoless Double- β Decay Experiments

Matteo Agostini

Munich Technical University (TUM)

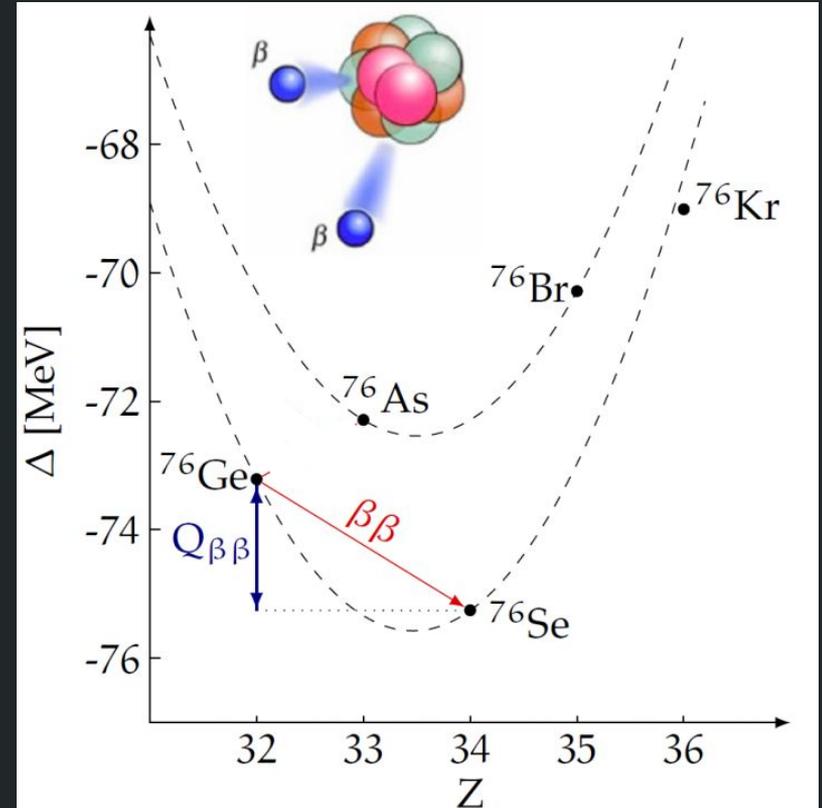

PhyStat-nu, CERN, Jan 22-25, 2019

Neutrinoless Double- β Decay ($0\nu\beta\beta$)

From the point of view of Nuclear Physics:

- second order nuclear transition
- atomic number Z increased by two units

[Courtesy of G. Benato]

Neutrinoless Double- β Decay ($0\nu\beta\beta$)

From the point of view of Nuclear Physics:

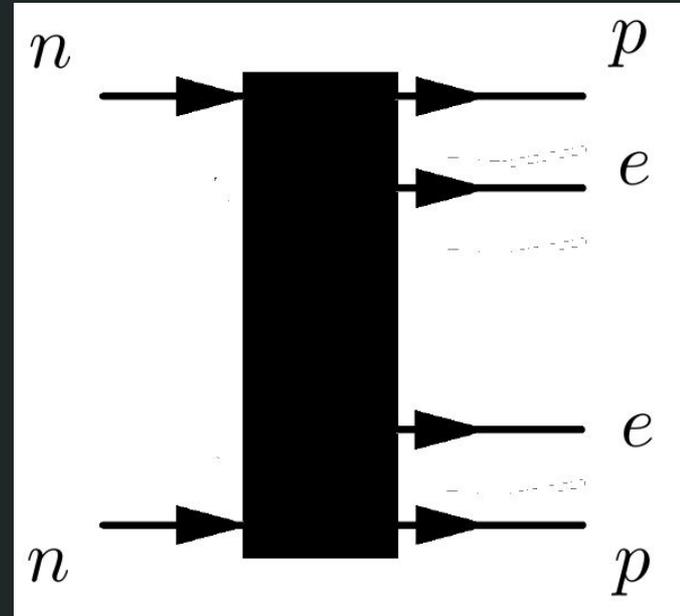

$$(A, Z) \rightarrow (A, Z + 2) + 2e^{-}$$

- second order nuclear transition
- atomic number Z increased by two units

From the point of view of Particle Physics:

$$2n \rightarrow 2p + 2e^{-}$$

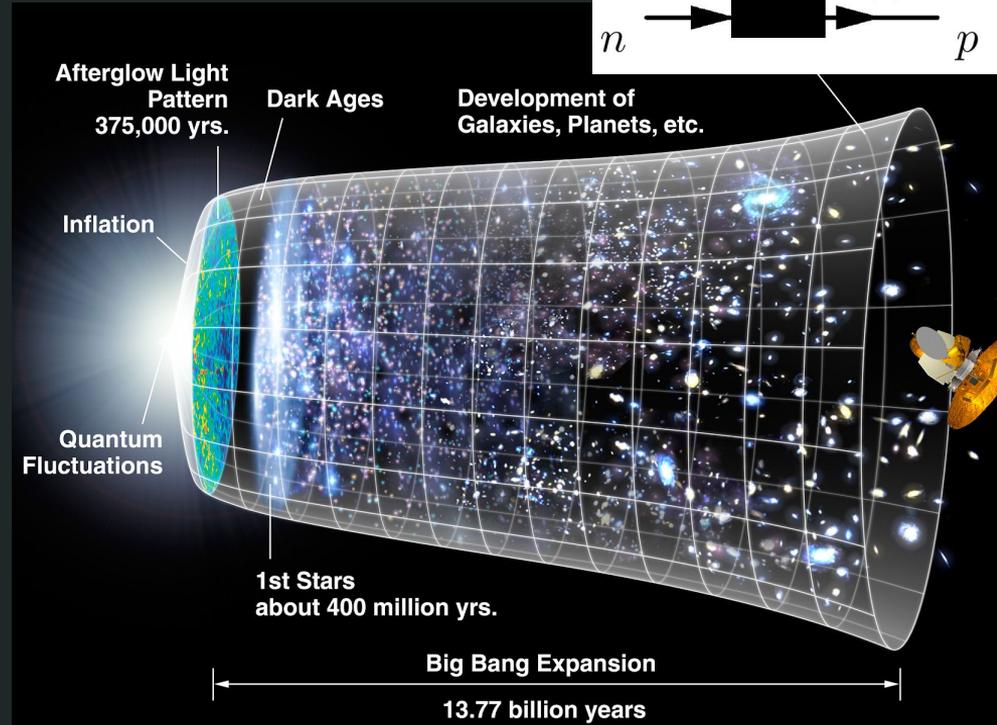

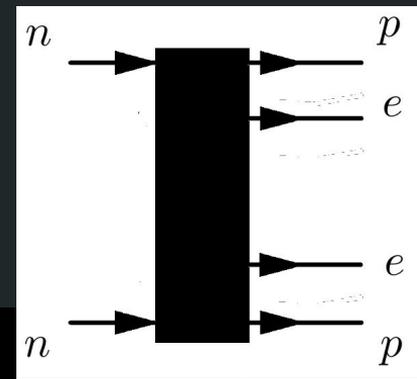

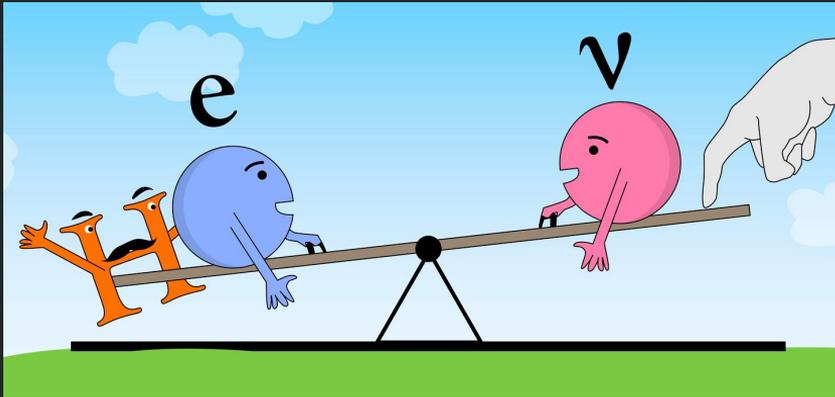

- channel depends on new physics
- 2 leptons produced w/o balancing anti-leptons

Neutrinoless Double- β Decay ($0\nu\beta\beta$)

If $0\nu\beta\beta$ decay is discovered:

- first observation of “matter creation”
- matter-antimatter asymmetry
- neutrinos are their own antiparticle
- origin neutrino masses

A portal to Physics beyond the Standard Model

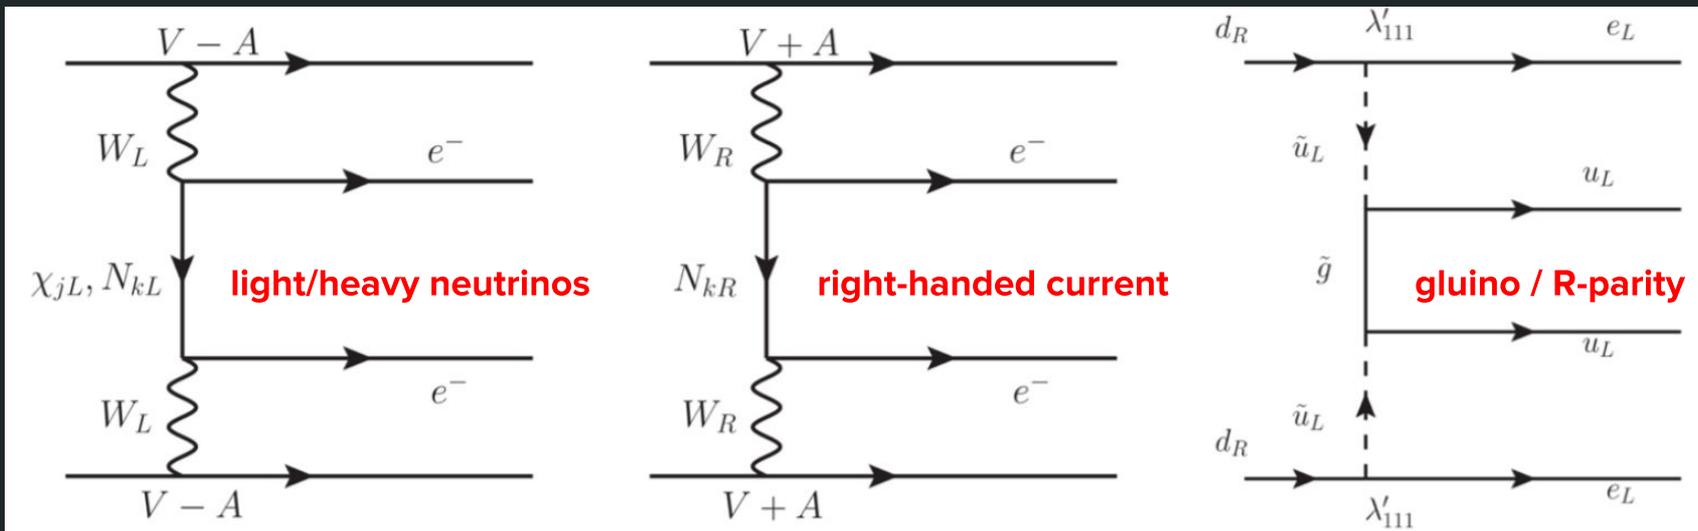

Decay probability proportional to coherent sum of involved mechanisms:

$$\Gamma = \frac{1}{T_{1/2}} = G(Q, Z) \times \left| \sum_i \mathcal{M}_i \times \eta_i \right|^2$$

Phase Space Factor

Nuclear Physics

Propagator

A portal to Physics beyond the Standard Model

Decay probability proportional to coherent sum of involved mechanisms:

$$\Gamma = \frac{1}{T_{1/2}} = G(Q, Z) \times \left| \sum_i \mathcal{M}_i \times \eta_i \right|^2$$

Phase Space Factor

Nuclear Physics

Propagator

Propagator factor:

- Connects decay probability to energy scale of new physics
- $T_{1/2}$ is for $0\nu\beta\beta$ decay what the **collision energy** is for **LHC**
- Scale of new physics is unknown and a signal can be around the corner -> important to increase the sensitivity on $T_{1/2}$

Strongest constraints

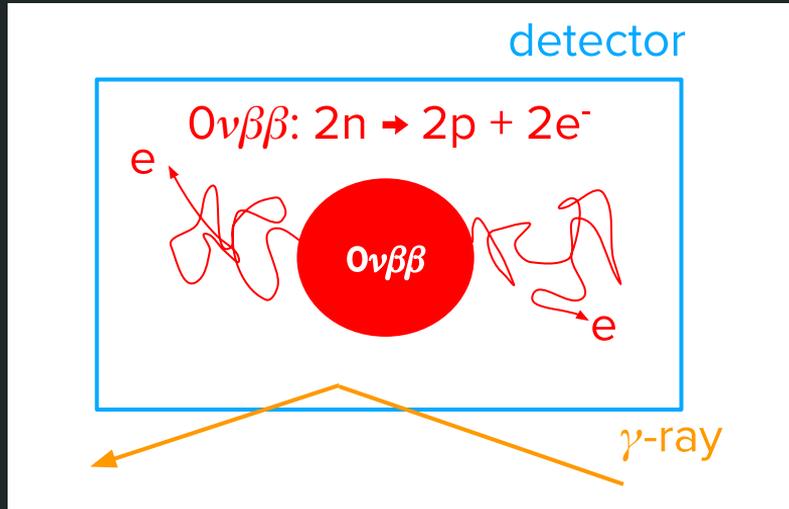

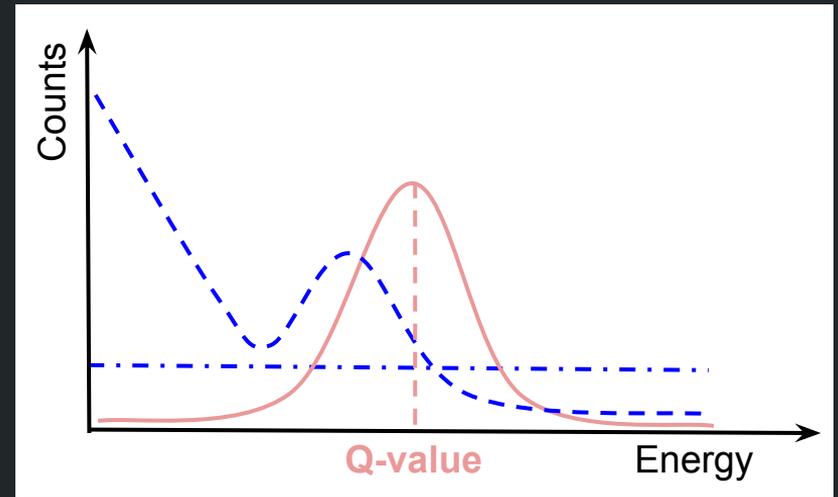

$$T_{1/2} > 10^{26} \text{ yr}$$

i.e. more than a **million trillion** times the age of the Universe!

Experiment design

Detection approach:

- source in detector active material
- detector acts as a calorimeter
- additional observables used to constrain background and systematics

Signal:

- spread due to energy resolution
- peak at Q-value (often Gaussian)

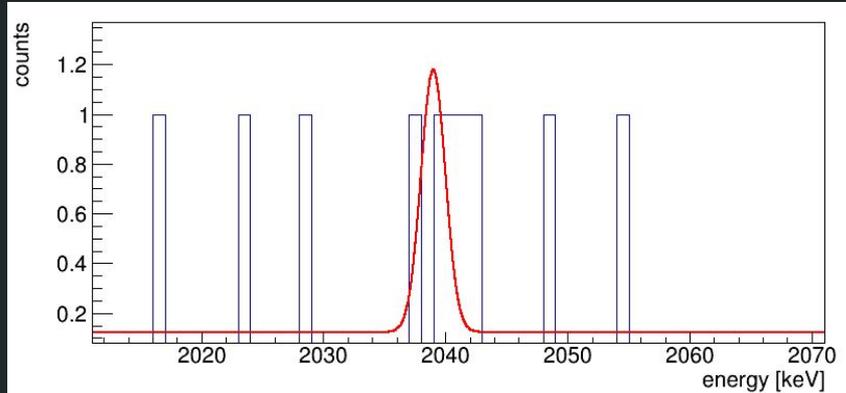

Background:

- typically flat if resolution is $<0.1\%$
- not connected to physics mechanism generating the signal \rightarrow hard to model!

Statistical analysis

Search for a peak at fixed position

- λ_S signal expectation (typically very small)
- λ_B background expectation
- **no look elsewhere**
- background control sample (on/off problem)

1. Counting:

$$\mathcal{L} = \text{Poisson}(\mathcal{N}_{\text{tot}}^{\text{obs}} | \lambda_S + \lambda_B) \cdot \text{Poisson}(\mathcal{N}_B^{\text{obs}} | \tau \lambda_B)$$

- N_{tot} number of cts in signal window
- N_B number of cts in control window
- τ ratio of windows size
- gives bulk of results
- window optimization is important

2. Binned ML spectral fit:

- full info on energy distribution
- goodness of background model

3. Extended Unbinned ML spectral fit:

- CPU convenient for sparse histogram
- not sensitive to background modeling

Statistical issues

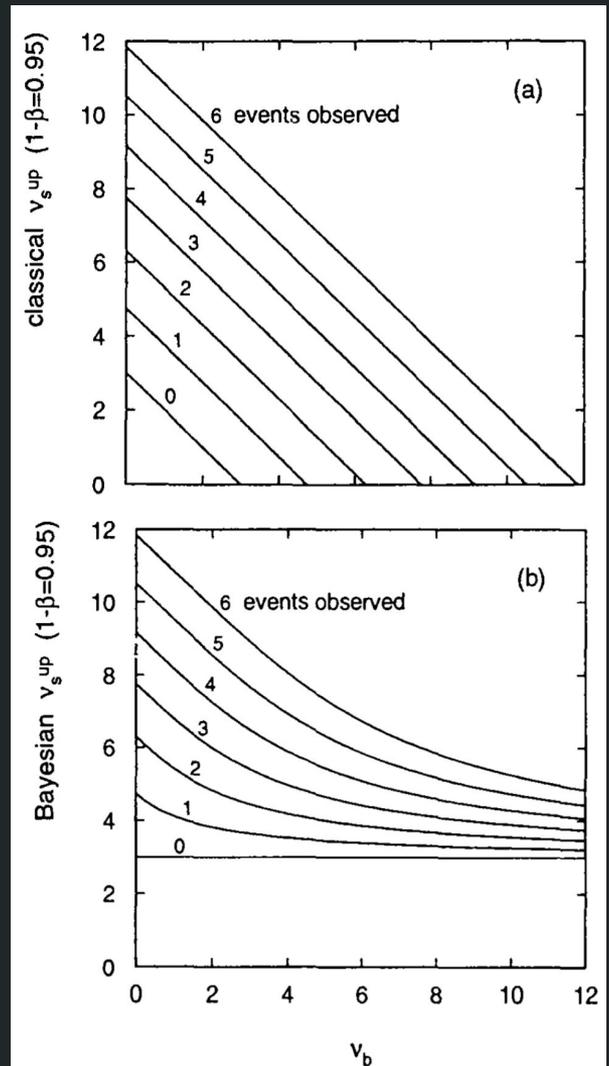

Frequentist framework:

- physical border ($\lambda_s \geq 0$)
- best fit in unphysical space when background under-fluctuates
- empty intervals emerge to preserve coverage
- stronger limits for higher background

Bayesian framework:

- low statistic \rightarrow strong impact of the prior

Large deviations between different techniques!

Frequentist methods

Two-sided test statistic:

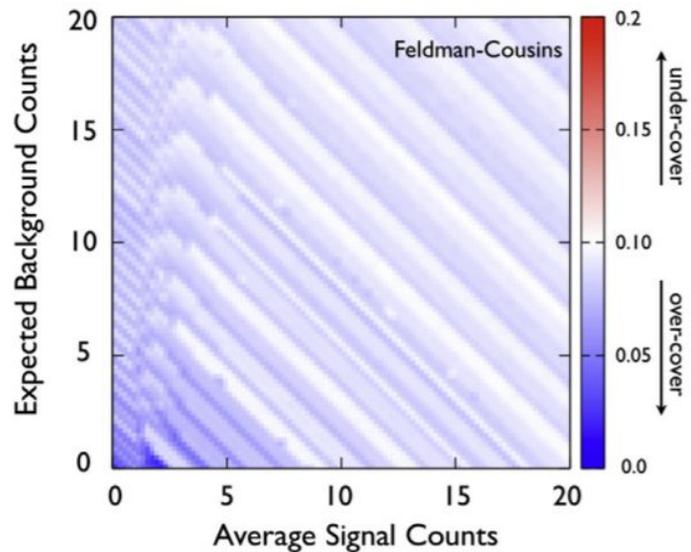

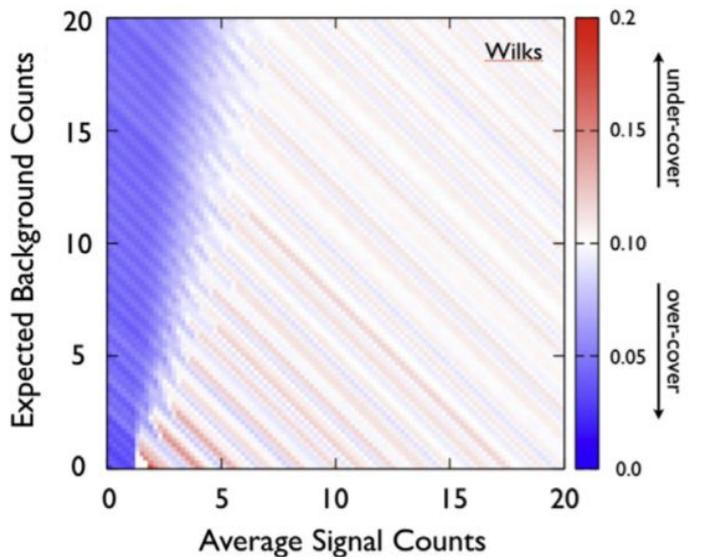

- χ^2
- profile likelihood

Confidence interval construction:

- Wilks' or Feldman Cousins (FC)
- λ_S bounded to positive values to avoid empty intervals

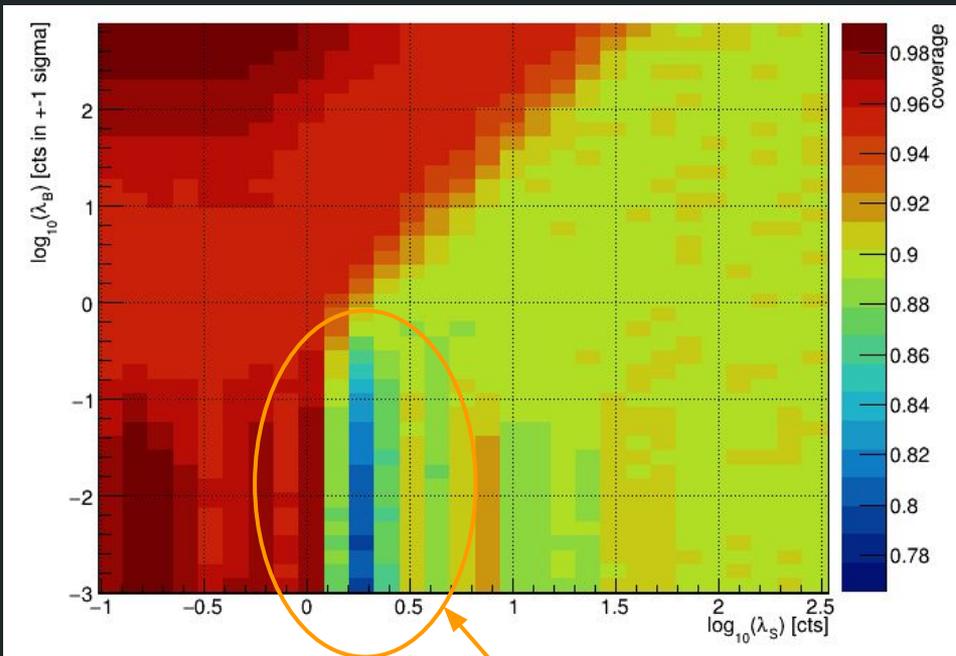

Coverage issues

- intrinsic in discrete problem
- Wilks' overcovers for $\lambda_S < \sqrt{\lambda_B}$
- FC overcovers for small λ_S

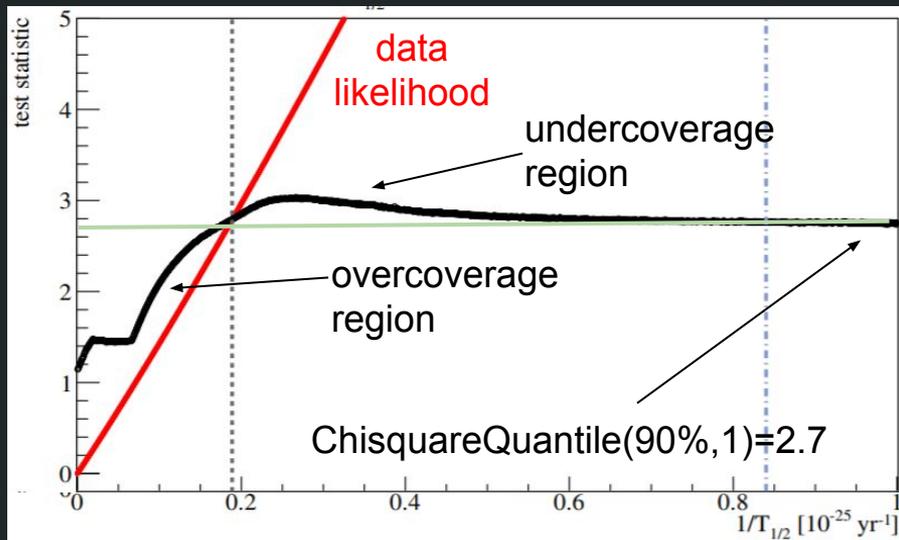

“Deep Poisson” regime

Spectral fit under Wilks' approximation

Background-free condition
Target of many experiments

Threshold of test statistic for a 90% CL derived through a FC construction (GERDA Phase II)

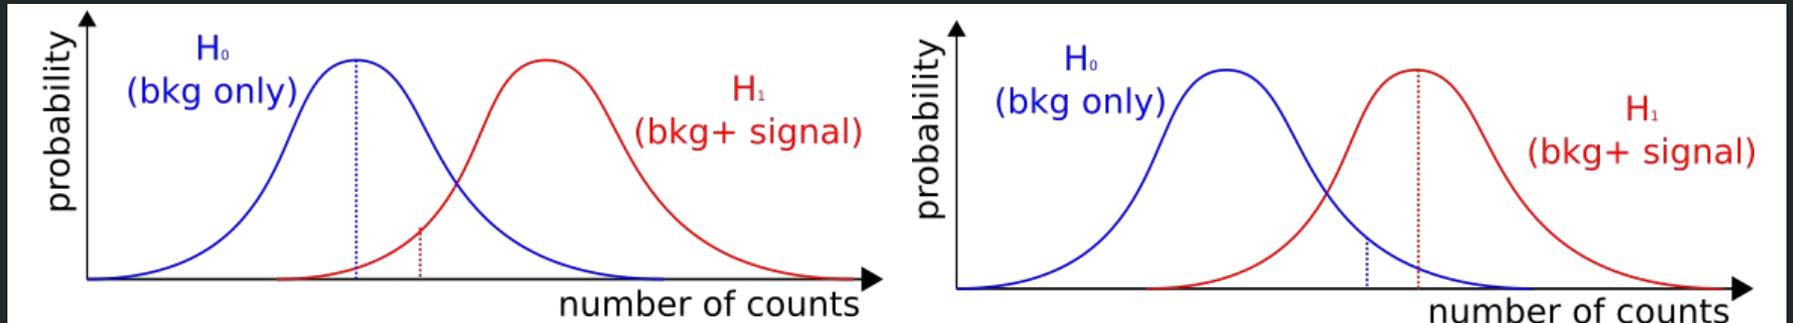

[V. Wagner, MPIK, PhD thesis]

Sensitivity Definitions

	CL	Concept	How to compute
limit setting	90%	Assuming there is no signal, what is the expected upper limit on the signal expectation?	find signal expectations that would be rejected with a median significance of 90% CL assuming the null hypothesis
signal discovery	99.7% (3σ)	Assuming there is a signal, how strong does it has to be to make a discovery?	find signal expectations for which the null hypothesis would be rejected with a median significance $\geq 3\sigma$

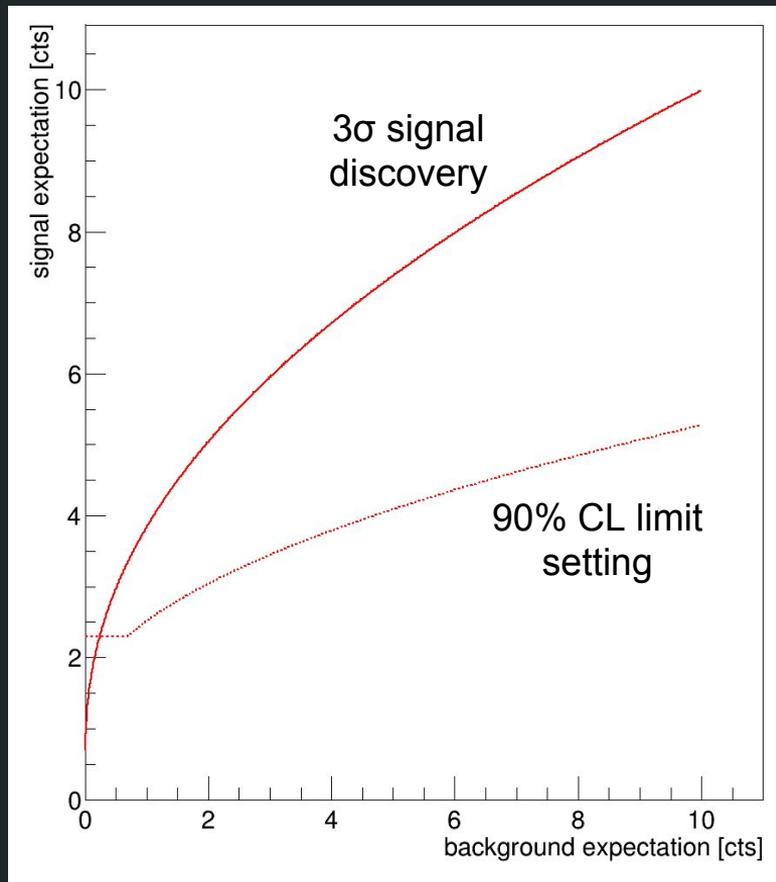

[Consistent with prescription from Cowan, Cranmer et al.]

Counting Experiment Sensitivity

Simple calculation for signal + known background:

- based on distributions of expected frequency of observations
- Poisson CDF approximated with gamma functions

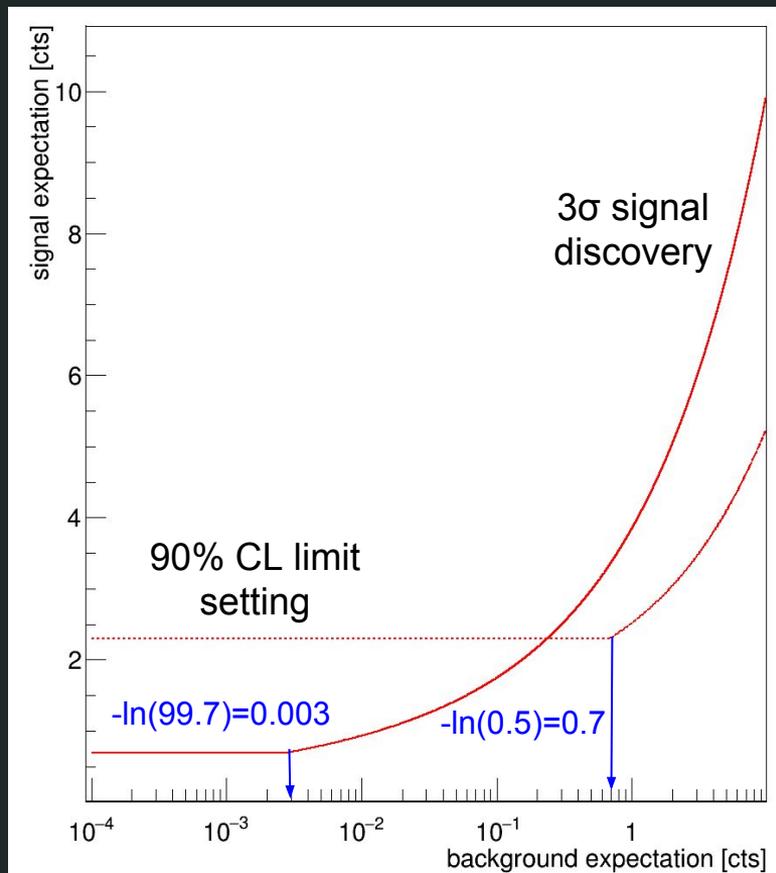

Counting Experiment Sensitivity

Simple calculation for signal + known background:

- based on distributions of expected frequency of observations
- Poisson CDF approximated with gamma functions

Background free regime:

- **limit setting sensitivity:** flattens for a background expectation of .7 cts (median of H_0 is at 0)
- **signal discovery sensitivity:** flattens for a background expectation of 0.003 (99.7% quantile of H_0 is at 0)
- 1 count is a discovery for low enough background

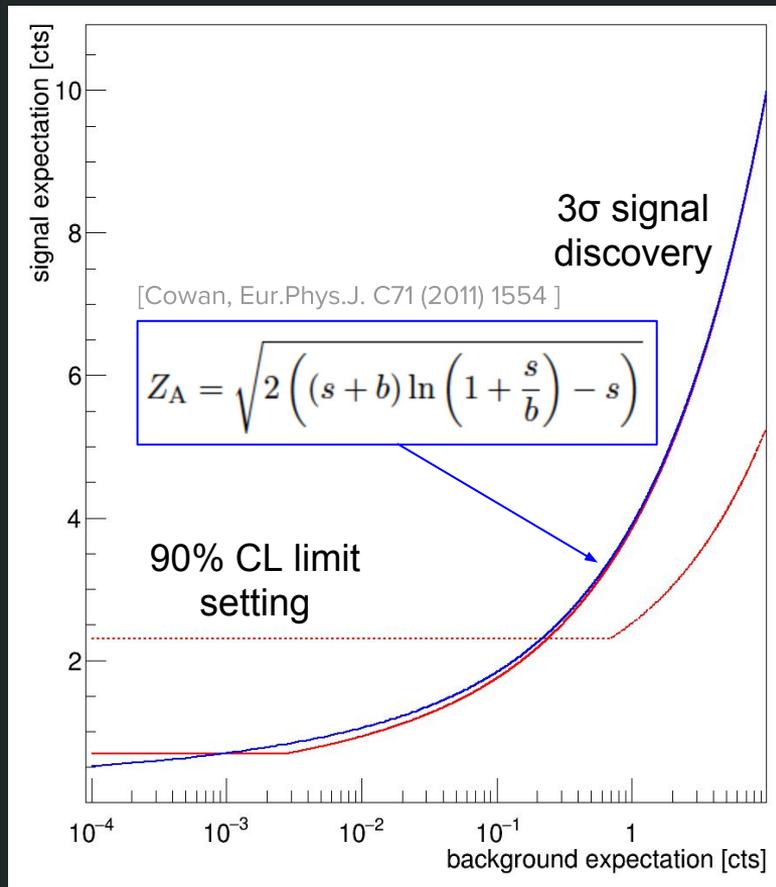

Counting Experiment Sensitivity

Simple calculation for signal + known background:

- based on distributions of expected frequency of observations
- Poisson CDF approximated with gamma functions

Background free regime:

- **limit setting sensitivity:** flattens for a background expectation of .7 cts (median of H_0 is at 0)
- **signal discovery sensitivity:** flattens for a background expectation of 0.003 (99.7% quantile of H_0 is at 0)
- 1 count is a discovery for low enough background

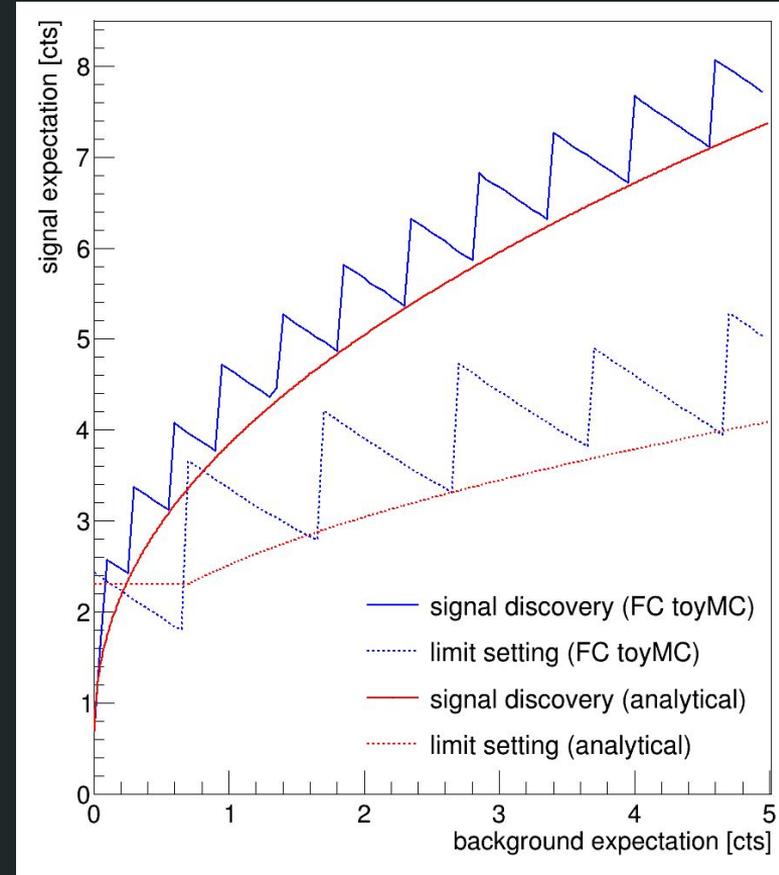

Counting Experiment Sensitivity

Comparison with a FC construction:

- likelihood ratio
- test statistic distributions from toy MC
- median significance (not mean!)

Features:

- jumps in coverage due to discrete nature of problem
- not monotonic functions -> apparent sensitivity improvement when increasing background
- “better than background free” regime

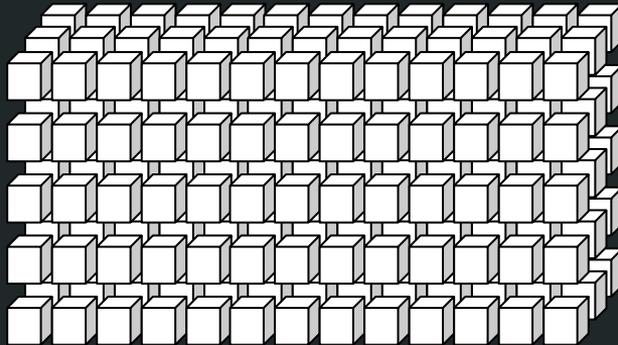

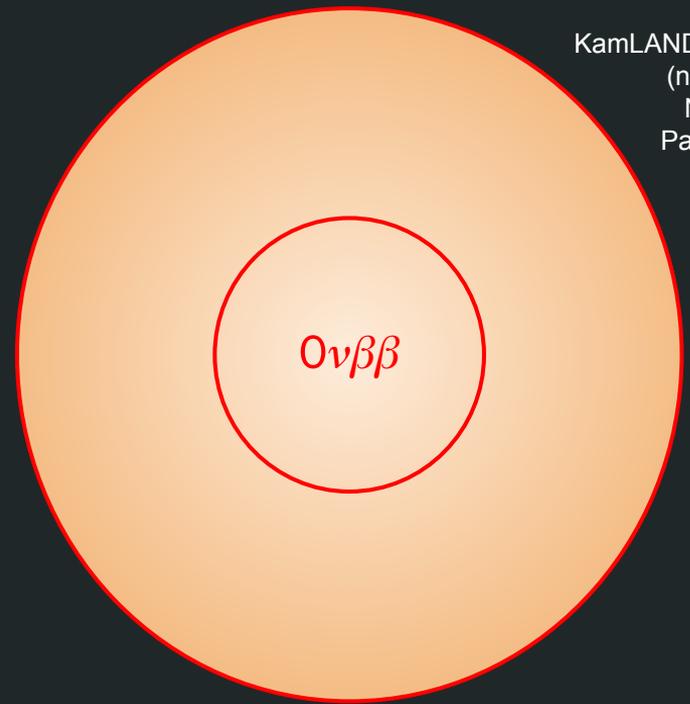

Liquid/Gas vs Solid Detectors

KamLAND-Zen
(n)EXO
NEXT
PandaX

Loaded scintillator detectors or Xe Time Projection Chambers

- $0\nu\beta\beta$ isotope mixed in the liquid/gas material
- self-shielding from external background
- volume fiducialization

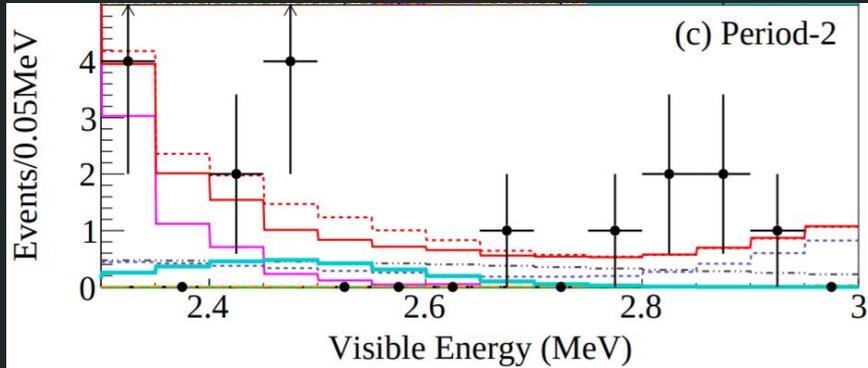

CUORE
CUPID
AMORE
Majorana
GERDA

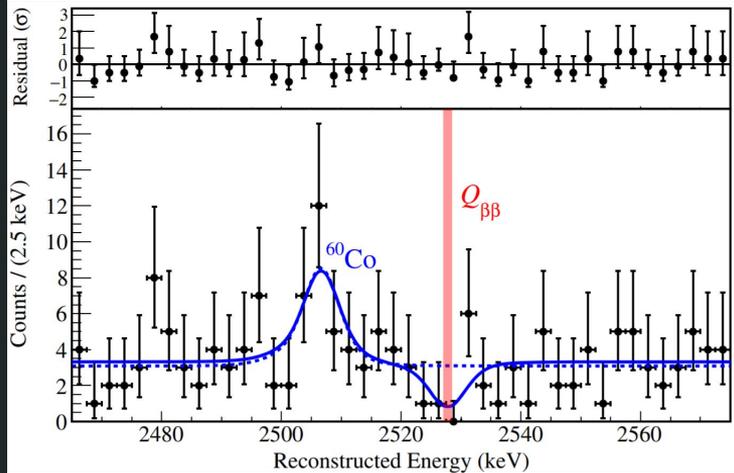

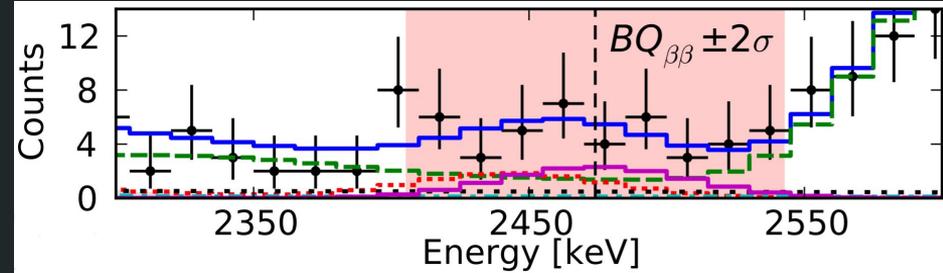

Cryogenic Bolometers or Semiconductor detectors:

- many crystals of isotopically enriched material
- detector granularity
- per mill energy resolution

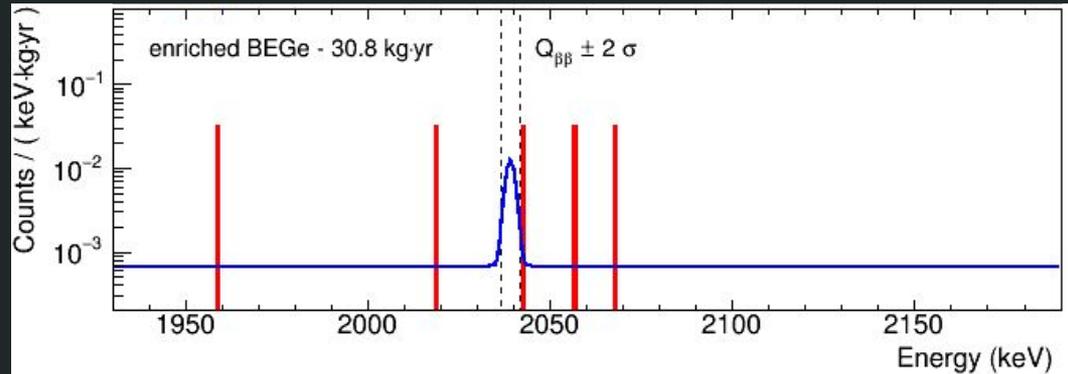

Liquid/Gas vs Solid Detectors

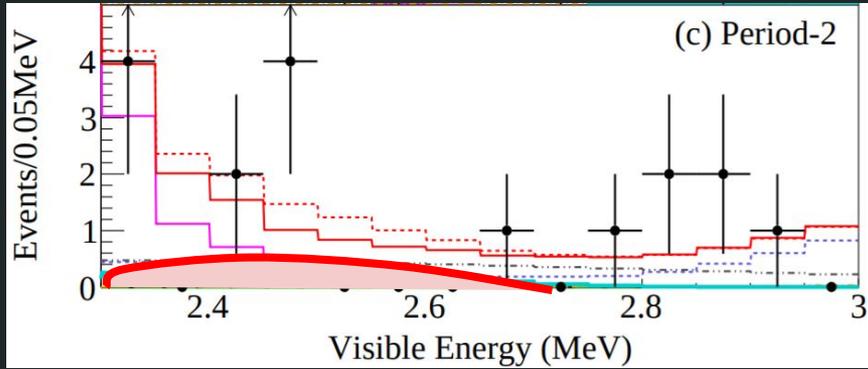

KamLAND-Zen
 $B=O(10)$ cts

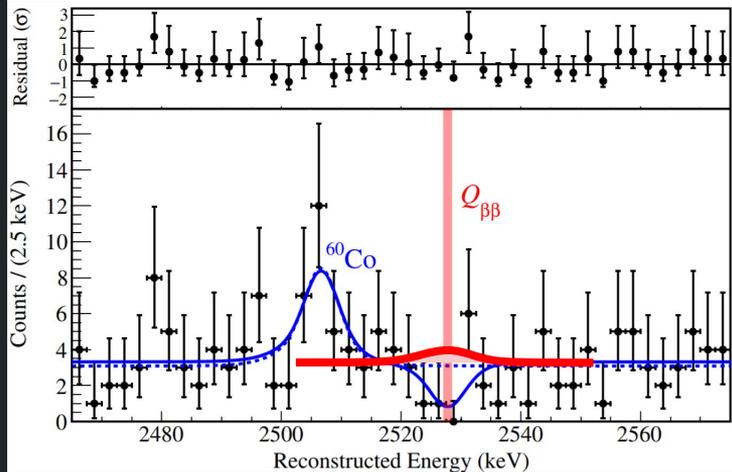

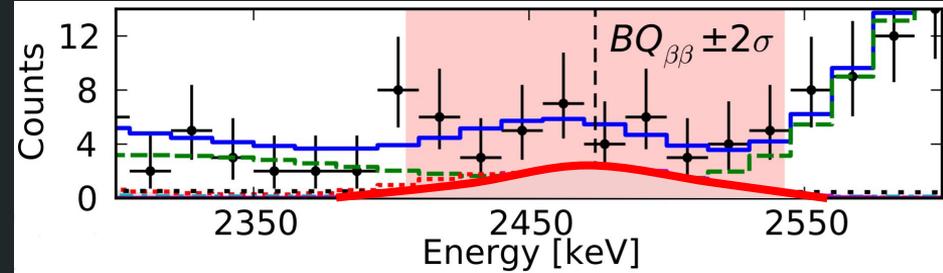

CUORE: $B=O(10)$ cts

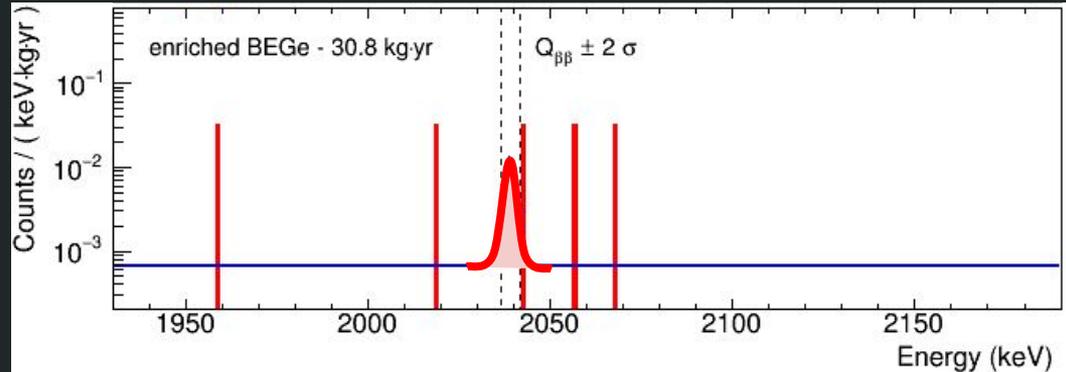

Liquid/Gas vs Solid Detectors

KamLAND-Zen
 $B=O(10)$ cts

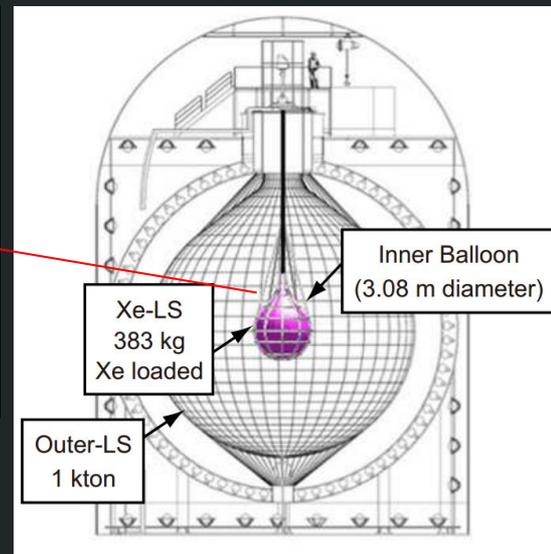

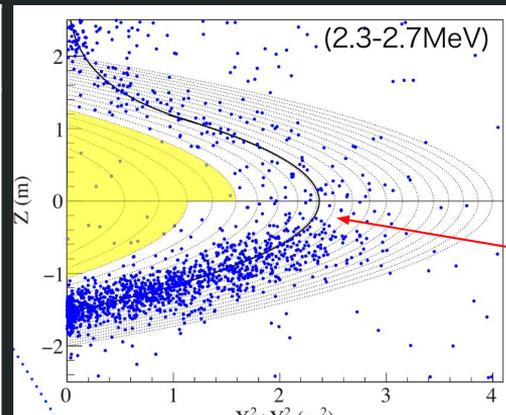

CUORE: $B=O(10)$ cts

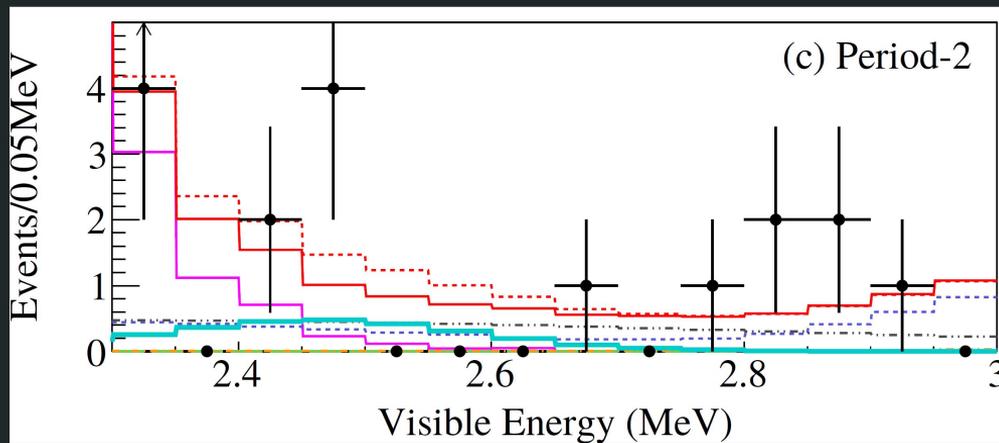

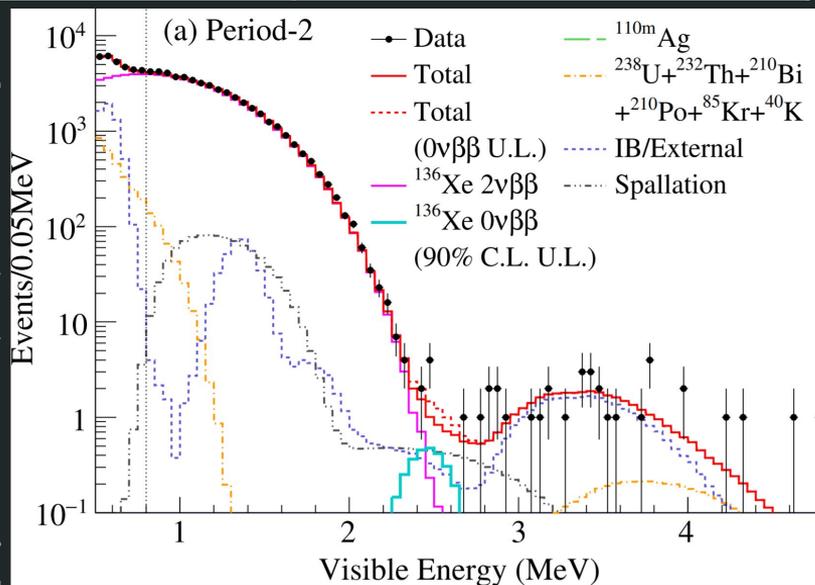

KamLAND-Zen

Location	Kamioka, Japan
Isotope	^{136}Xe [$Q_{\beta\beta} = 2458$ keV]
Technology	Xe-loaded liquid scintillator
Isotope Mass	350 kg
$0\nu\beta\beta$ efficiency	16%
Resolution [σ]	100-120 keV
Latest results	$T_{1/2} > 1.1 \cdot 10^{26}$ yr (90% CL)
Sensitivity	$T_{1/2} > 5.6 \cdot 10^{25}$ yr (90% CL)

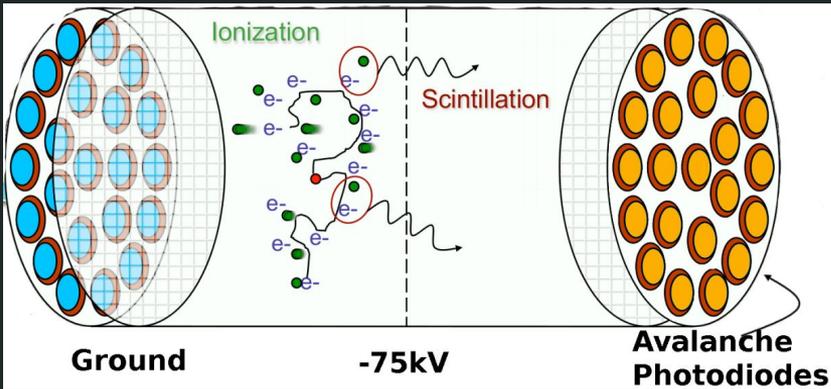

Frequentist likelihood fit

- Multivariate: E vs R
- Wilks' approximation tested with toy MC

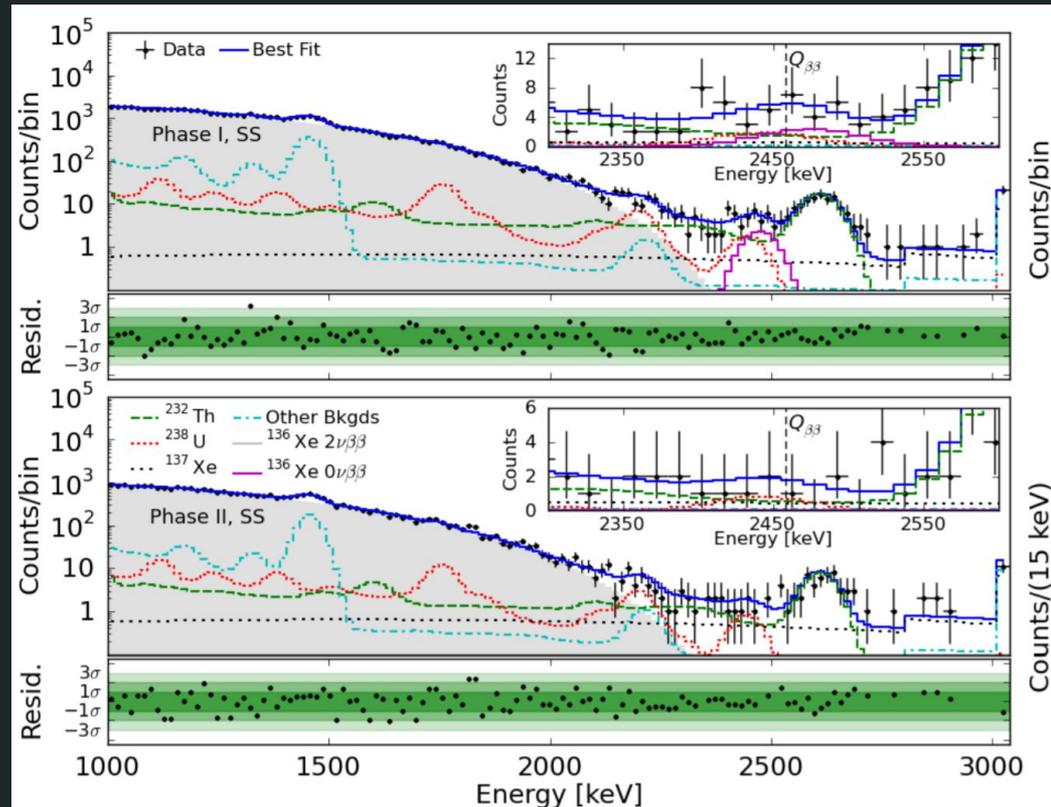

EXO-200

Location	WIPP, New Mexico, USA
Isotope	^{136}Xe [$Q_{\beta\beta} = 2458 \text{ keV}$]
Technology	TPC with liquid Xe
Isotope Mass	76 kg
$0\nu\beta\beta$ efficiency	80%
Resolution [σ]	34 keV
Latest results	$T_{1/2} > 1.8 \cdot 10^{25} \text{ yr}$ (90% CL)
Sensitivity	$T_{1/2} > 3.7 \cdot 10^{25} \text{ yr}$ (90% CL)

[Phys.Rev.Lett. 120 (2018) no.7, 072701]

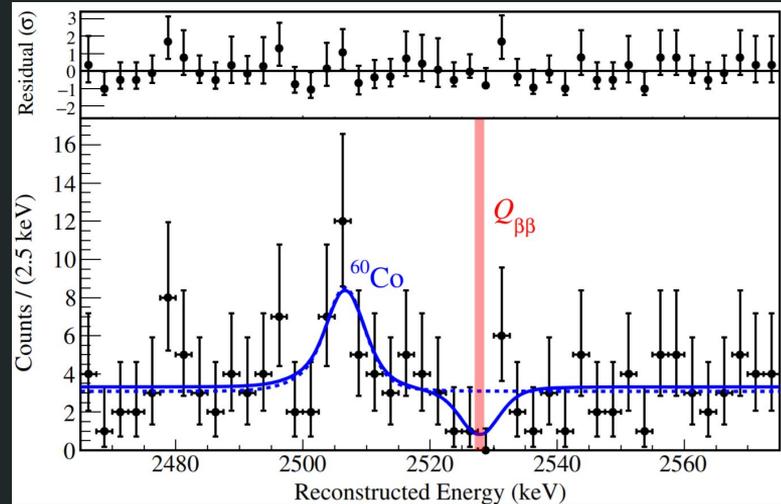

Frequentist binned likelihood fit:

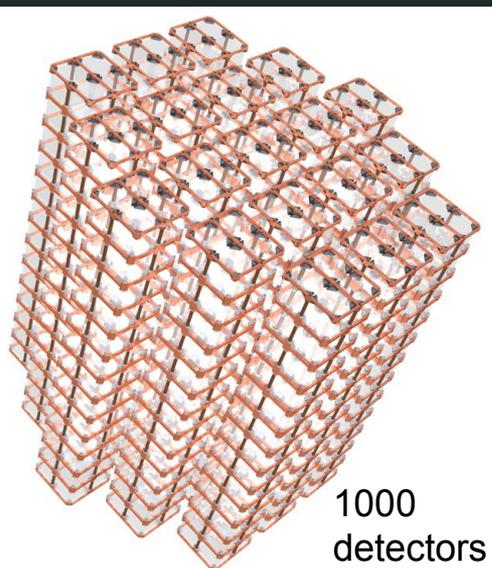

- multivariate (energy, position, TMVA observables)
- Wilks' approximation valid (coverage tested)

CUORE

Location	LNGS, Italy
Isotope	^{130}Te [$Q_{\beta\beta}=2527$ keV]
Technology	Cryogenic calorimeters
Isotope Mass	206 kg
$0\nu\beta\beta$ efficiency	68%
Resolution [σ]	3.3 keV
Latest results	$T_{1/2} > 1.5 \cdot 10^{25}$ yr (90% CL)
Sensitivity	$T_{1/2} > 0.7 \cdot 10^{25}$ yr (90% CL)

[Phys. Rev. Lett. 120, 132501 (2018)]

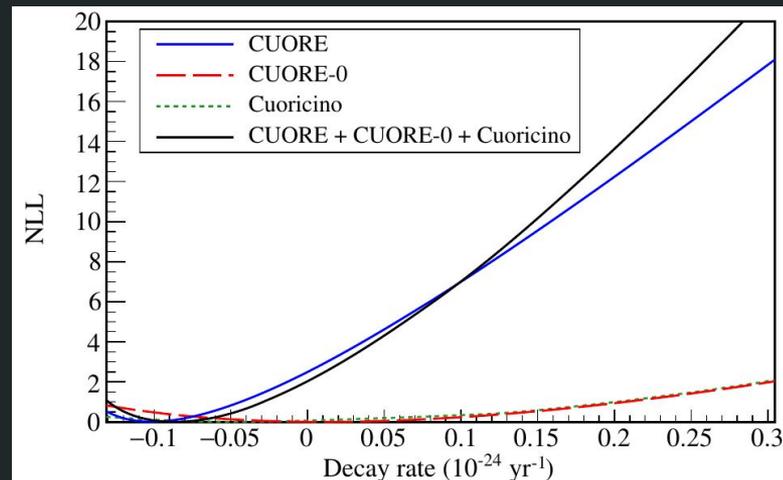

Bayesian:

- flat prior
- profiling instead of marginalization

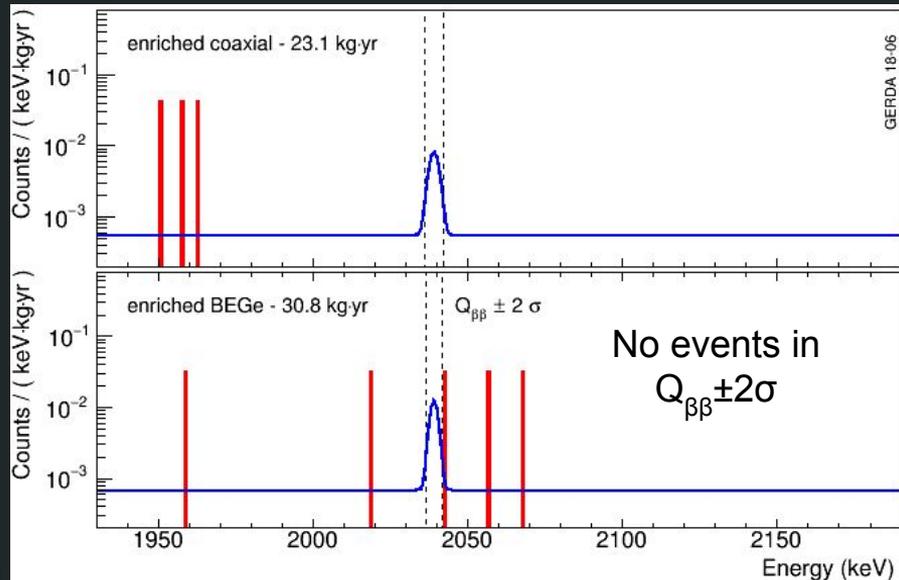

Frequentist:

- bounded profile likelihood
- Wilks approximation

GERDA

Location	LNGS, Italy
Isotope	^{76}Ge [$Q_{\beta\beta}=2039$ keV]
Technology	Semiconductor Ge detectors
Isotope Mass	35 kg
$0\nu\beta\beta$ efficiency	65%
Resolution [σ]	1.3 keV
Latest results	$T_{1/2} > 0.9 \cdot 10^{26}$ yr (90% CL)
Sensitivity	$T_{1/2} > 1.1 \cdot 10^{26}$ yr (90% CL)

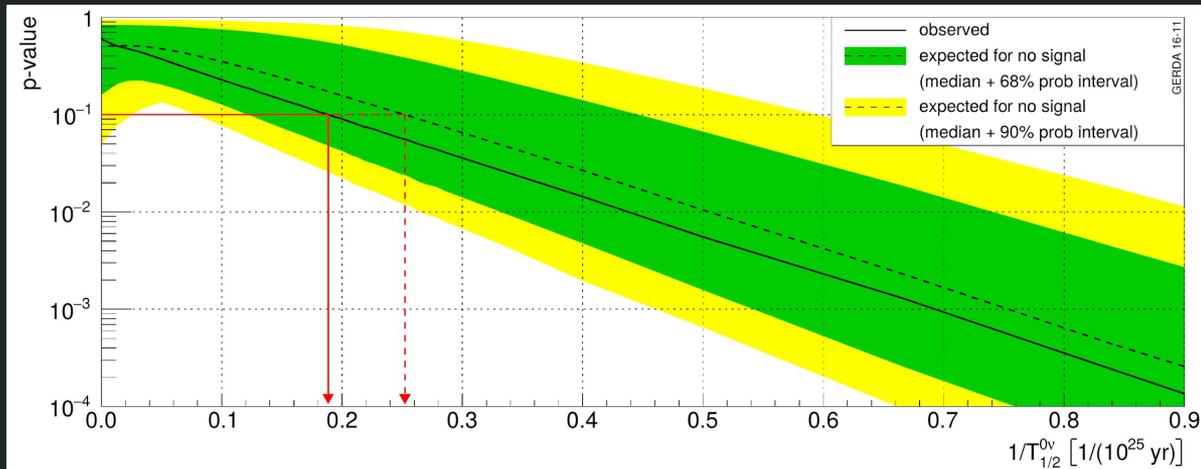

Frequentist:

- extended unbinned likelihood
- profile likelihood
- FC construction (only for best fit value of nuisance parameters)

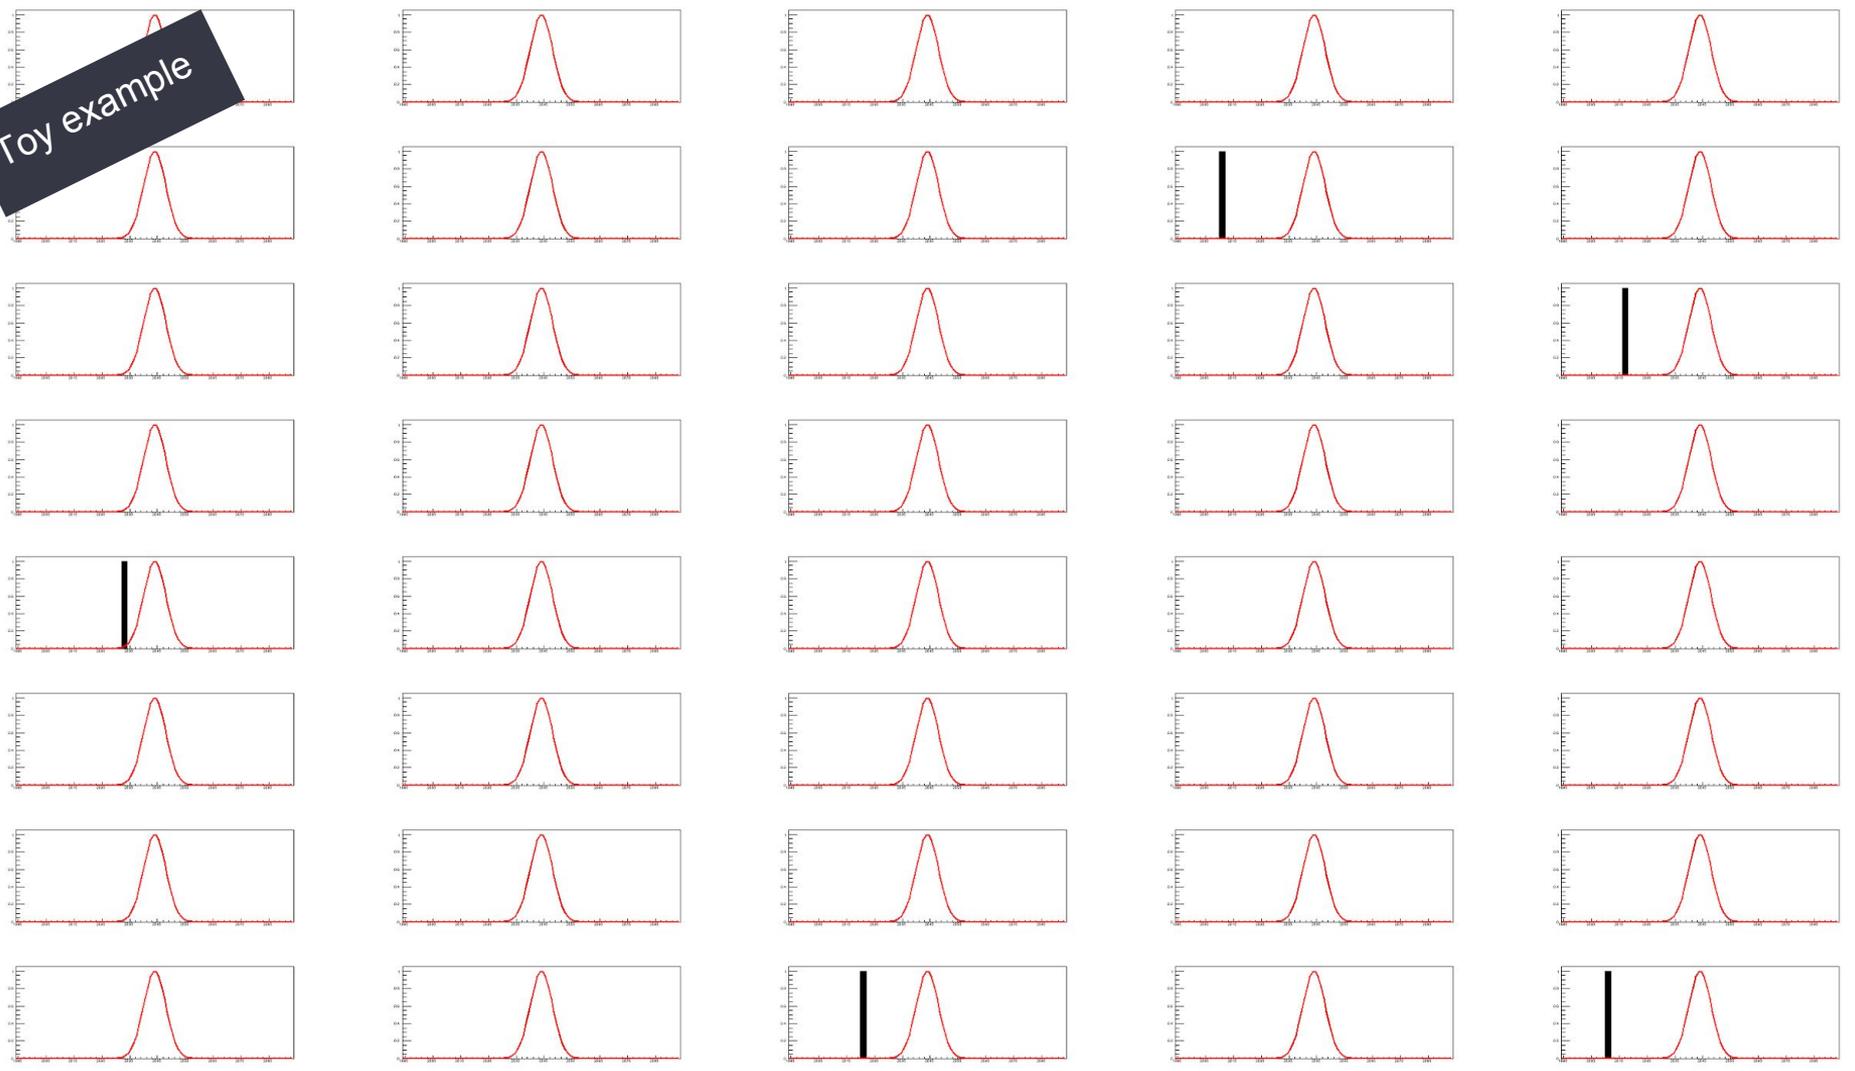

Bayesian:

- flat prior

[Nature 544 (2017) 47]

Toy example

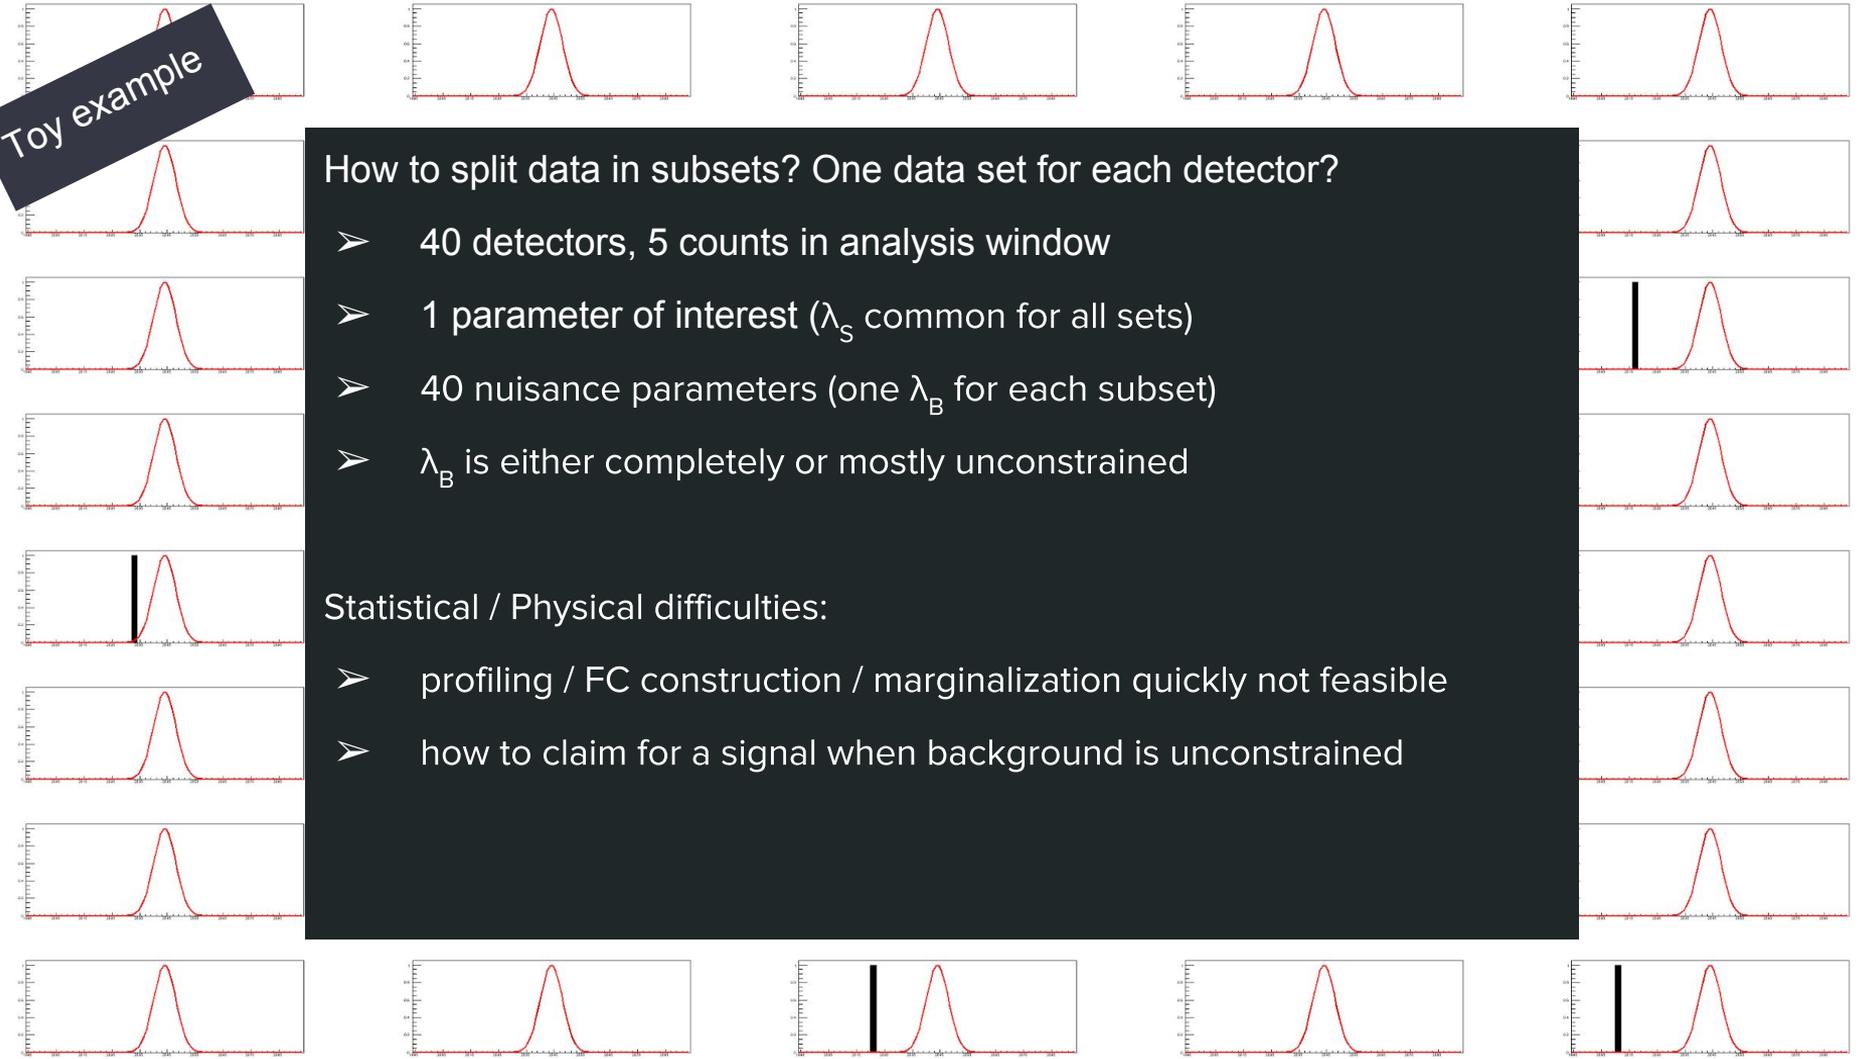

Toy example

How to split data in subsets? One data set for each detector?

- 40 detectors, 5 counts in analysis window
- 1 parameter of interest (λ_S common for all sets)
- 40 nuisance parameters (one λ_B for each subset)
- λ_B is either completely or mostly unconstrained

Statistical / Physical difficulties:

- profiling / FC construction / marginalization quickly not feasible
- how to claim for a signal when background is unconstrained

Discovery analysis with 1 candidate event

Conceptual problem:

- focus on a single signal-candidate event
- this event comes with a set of experimental parameters
- we feel like the analysis should use those parameters and not average values over a data set
- splitting data in more sets would reduce the difference between average parameters and those of a single event but leads to proliferation of nuisance parameters associated to empty data sets and larger uncertainties on their central values

Current approach:

- find a trade-off between number of data sets and variance of the average parameters
- blinded analysis (including blinded data set definition) avoid biases in the process

Systematics

Main systematics:

- background shape (liquid/gas experiments)
- energy scale and resolution
- signal detection efficiency
 - active volume
 - analysis cuts
 - ...

Approaches:

- nuisance parameters / pull terms
- fit with different models
- toy-MC generated under different models

Impact of systematic uncertainties

- not informative data -> impact determined by shape of priors or pull term
- 1% level for solid state detectors (no counts to pull nuisance parameters)
- 5-10% level for gas/liquid experiments
- different in case of signal

EXO-200 systematic uncertainties:

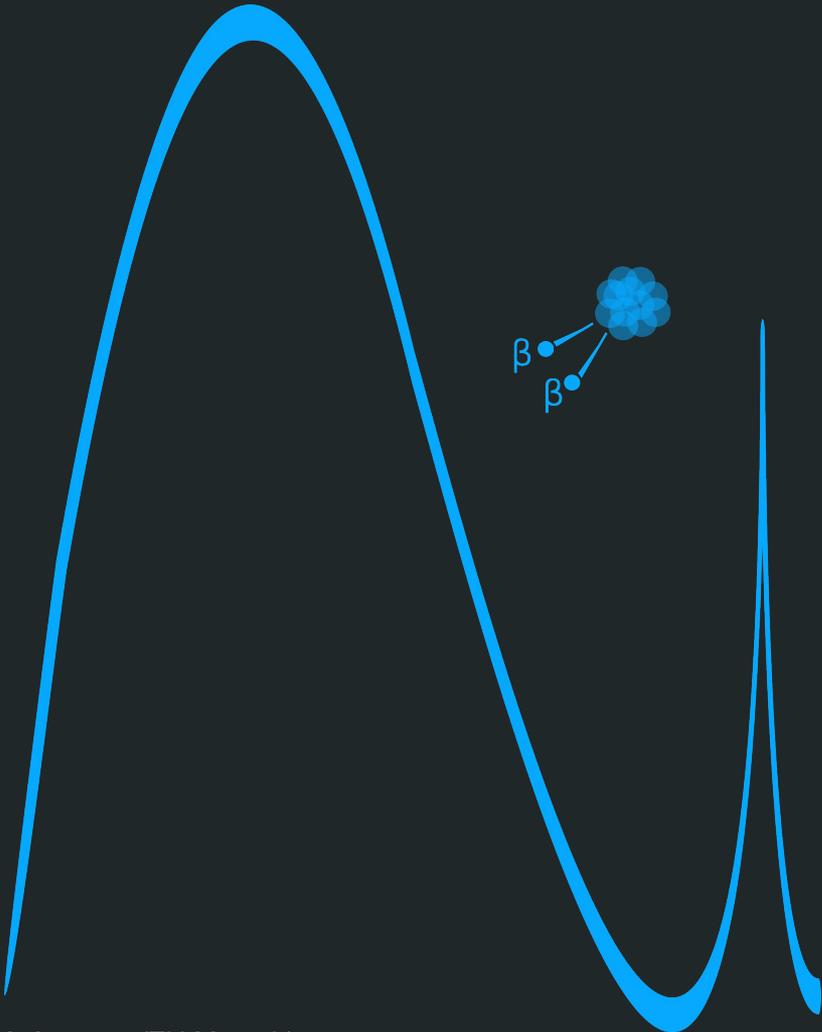

Source	Phase I	Phase II
Signal detection efficiency	3.0%	2.9%
Background errors		
Spectral shape agreement	2.1%	1.7%
Background model	5.6%	5.9%
Energy scale and resolution	1.5%	1.2%
Total	6.2%	6.2%

Statistics & Double- β Decay Community

[Phys. Rev. Lett. 120, 132502 (2018)]

- most experiments quote results from multiple methods and give enough info to reproduce the analysis
- sensitivity always reported (sometimes also for Bayesian methods)
- blind analysis is almost the standard
- frequentist intervals still used as Bayesian intervals (even when Bayesian interval is available)
- sensitivity computed for the no signal hypothesis, more interesting to quote discovery power

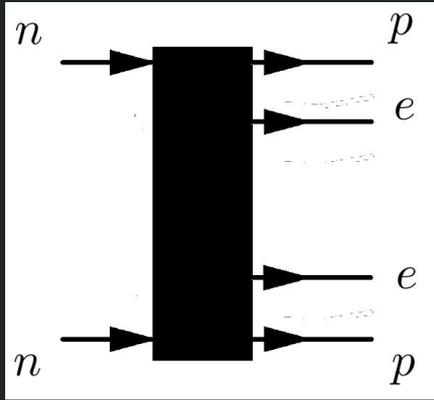

Statistical Method in the last PRL of the MAJORANA DEMONSTRATOR	$T_{1/2}$ lower limit 90% prob [10^{25} yr]	$T_{1/2}$ lower limit sensitivity [10^{25} yr]
Counting (FC)	1.6	
Unbinned likelihood fit (FC)	1.9	2.1
Unbinned likelihood fit & CLs	1.5	1.4
Bayesian flat prior	1.6	
Bayesian Jeffreys prior	2.6	

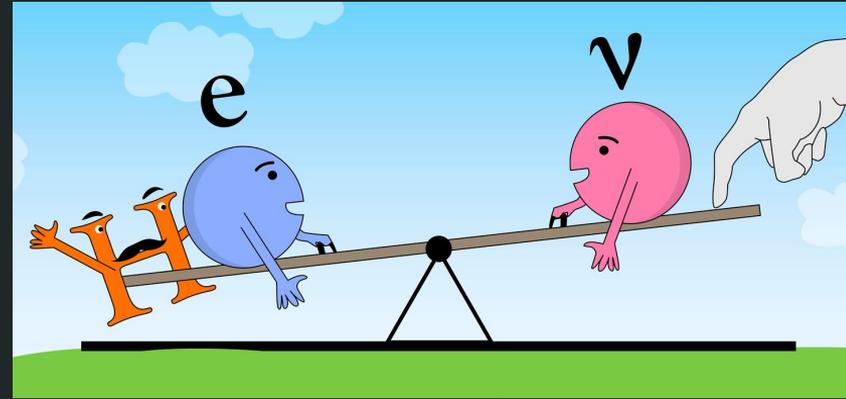

Outlook

- $0\nu\beta\beta$ decay is a portal to new physics and experiments are interested in signals at the edge of their sensitivity
- The search for a peak with background keeps on posing new challenges: (too) many methods available, very different results
- Many experiments operate in the “Deep Poisson” regime where even a simple concept as sensitivity requires attention
- Important to shift focus towards a discovery analysis and define in advance how to deal with it a discovery based on a single count

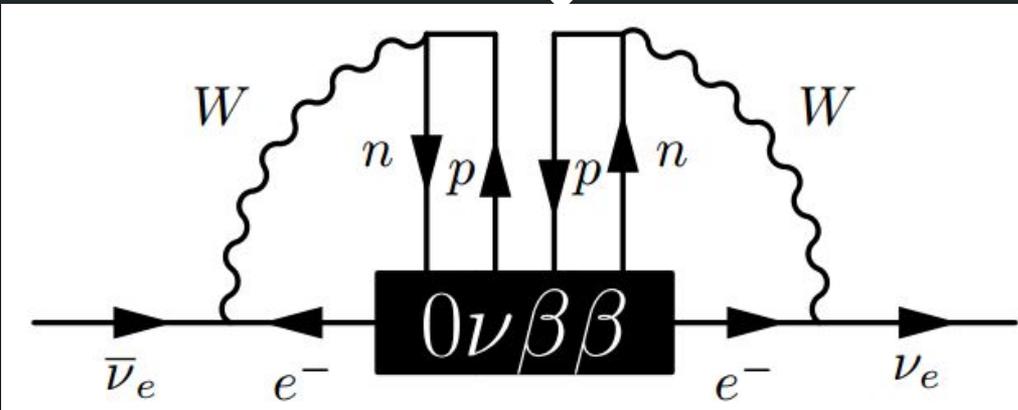

$0\nu\beta\beta$ and ν Mass Origin

Black Box theorem:
 $0\nu\beta\beta$ operator can be rearranged
 into a $\nu\bar{\nu}$ oscillation
 (i.e. a Majorana mass term)

[www.symmetrymagazine.org]

If $0\nu\beta\beta$ decay is discovered:

- neutrinos are their own antiparticle
- neutrinos can have a Majorana mass
- neutrino small masses can be explained through see-saw models

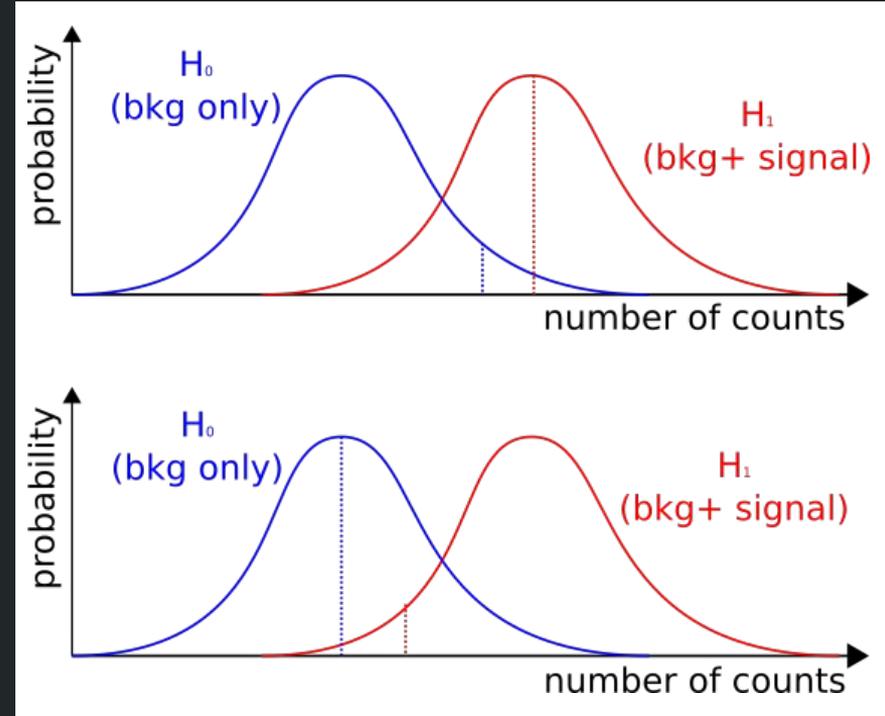

Sensitivity of an experiment

➤ 3σ signal discovery sensitivity

assuming there is a signal, find H_1 such that H_0 is rejected at 3σ in 50% of the cases

➤ 90% CL limit setting sensitivity

assuming there is no signal, find H_1 that is rejected in at 90% CL in 50% of the cases

Analytical computation of sensitivity

Signal discovery

- Find the number of counts $C_{3\sigma}$ such that: $\text{CDF}(C_{3\sigma}|B) = \text{erf}(3/\sqrt{2})$
- Solve: $\text{CDF}(C_{3\sigma} | S_{3\sigma} + B) = 50\%$
- $C_{3\sigma}$ is an integer: $S_{3\sigma}$ has discrete jumps → Approximate the Poisson CDF with the upper incomplete gamma function so that the above equations can be inverted with standard numerical methods

Limit Setting:

- Find the median number of cts expected from bkg only C_{med} : $\text{CDF}(C_{\text{med}}|B) = 50\%$
- Solve: $\text{CDF}(C_{\text{med}} | S_{90\%CL} + C_{\text{med}}) = 10\%$

[more in M.A. et al., Phys.Rev. D96 (2017) no.5]

The counting experiment with a profile likelihood

if **B** is perfectly known:

B := background expectation

S := signal expectation

N := number of cts in ROI

$$L(\mathbf{s}) = \text{Pois}(\mathbf{N}|\mathbf{S}+\mathbf{B})$$

$$t(\mathbf{s}) = -2 [\text{Pois}(\mathbf{N}|\mathbf{S}+\mathbf{B}) - \text{Pois}(\mathbf{N}|\mathbf{S}_{\text{best}}+\mathbf{B})]$$

$$\text{with } \mathbf{S}_{\text{best}} = \max(0, \mathbf{N}-\mathbf{B})$$

if **B** is derived from a side band or control region:

τ := side band width / ROI width

(for GERDA: $\tau = 220/6 \sim 40$)

M := number of cts in side band

$$L(\mathbf{s}) = \text{Pois}(\mathbf{N}|\mathbf{S}+\mathbf{B}) * \text{Pois}(\mathbf{M}|\tau\mathbf{B})$$

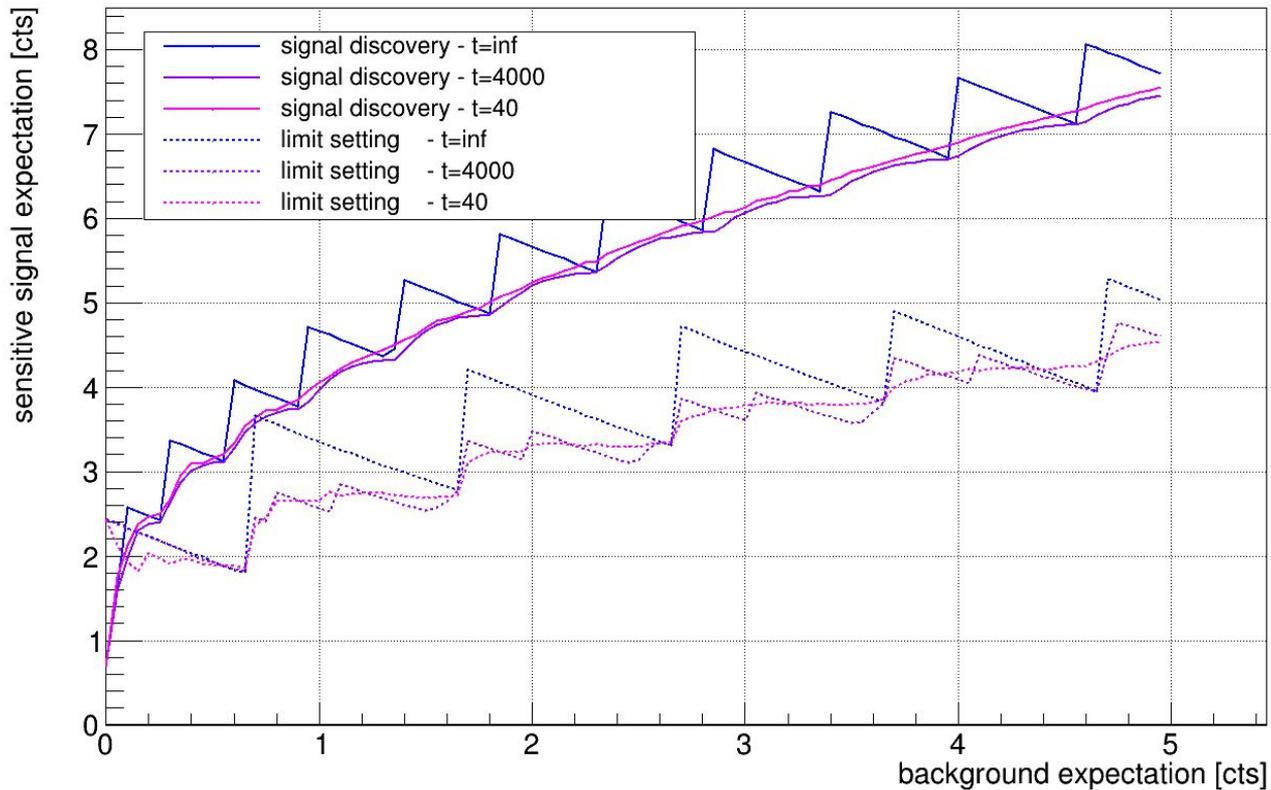

$$t(\mathbf{s}) = -2[\text{LogPois}(\mathbf{N}|\mathbf{S}+\mathbf{B}_{\text{cond}}) + \text{LogPois}(\mathbf{M}|\tau\mathbf{B}_{\text{cond}}) \\ - \text{LogPois}(\mathbf{N}|\mathbf{S}_{\text{best}}+\mathbf{B}_{\text{best}}) - \text{LogPois}(\mathbf{M}|\tau\mathbf{B}_{\text{best}})]$$

$$\text{with: } \mathbf{S}_{\text{best}} = \mathbf{N}-\mathbf{M}/\tau,$$

$$\mathbf{B}_{\text{best}} = \mathbf{M}/\tau$$

$$\mathbf{B}_{\text{cond}} = \mathbf{N}+\mathbf{M}-(1+t)\mathbf{S} + \text{sqrt}((\mathbf{N}+\mathbf{M}-(1+t)\mathbf{S})^2 + 4(1+t)\mathbf{S}\mathbf{M}) / [2(1+t)]$$

Probability Density from Global Fits

In absence of neutrino mass mechanisms or flavour symmetries that fix the value of the Majorana phases or drive m_{light} to zero, the probability distribution for $m_{\beta\beta}$ is pushed to large values:

[M.A., G Benato and J A Detwiler, PRD 96, 053001 (2017)]

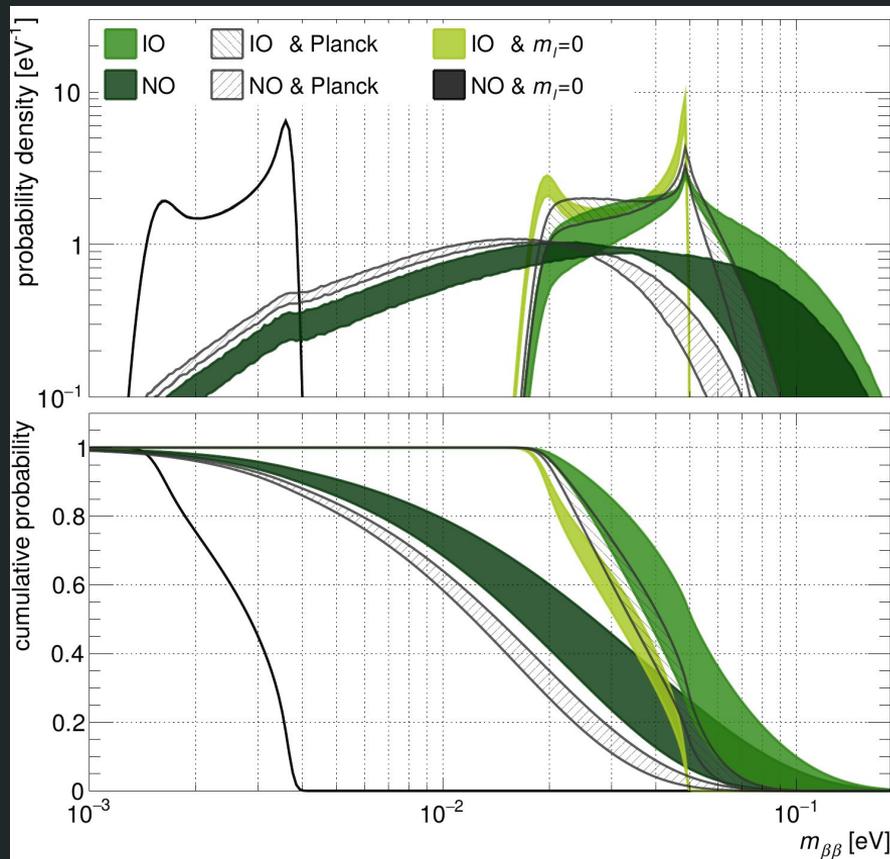

Flat prior for the Majorana phases \rightarrow small $m_{\beta\beta}$ values require a fine tuning of the parameters

Probability density from global fits

- data in the analysis: oscillations + $0\nu\beta\beta$ + (cosmology)
- bands shows deformation due to NME uncertainty
- $0\nu\beta\beta$ constraints on $m_{lightest}$ competitive with cosmology

Bulk of probability at reach with next generation experiments
