

Possible Design of a Solid Wire BBLR Compensator

A. Bertarelli, L. Gentini, M. Pasquali, A. Rossi (CERN)

with contributions from F. Carra, A. Dallocchio, S. Fartoukh, C. Fichera, M. Garlaschè, S. Mathot, F. Motschmann, Y. Papaphilippou, G. Sterbini, M. Timmins

8th HL-LHC Collaboration Meeting
CERN 18/10/2018

Context

- Beam-Beam Long-Range Compensators with physical wires are considered a valuable options for HL-LHC to **increase dynamic aperture at small crossing angles**
 - either in conjunction with Crab Cavities (HL-LHC round optics)
 - or as back-up solution (without Crab Cavities) with HL-LHC flat optics
- Requested in LHC Performance Workshop 2018 and 2018 HL-LHC Cost and Schedule:
 - Technical proposal for the HL-LHC wires integration by 2019-2020
- A space reservation of 4.5 m was made for both beams on either sides of IP1 and IP5

Initial Requirements (as understood)

- **1 wire per beam** per side of IP1 and IP5 → **8 wires** (4 H-wires and 4 V-wires depending on IP1/5 crossing angle)
- **Single wire** positioned in a vacuum chamber
- **Round wire** cross-section
- Wire total active length **3 m**
- Up to **400 Am DC** per wire (may be 220 Am depending on the chosen configuration), **133 A**
- Lateral stroke of the chamber ~ **15 mm** (parking wire at ~ 30 mm from beam?)
- Energy deposited by beam halo / particle showers not taken into account (particle tracking and FLUKA required)

The Idea

- Use a slim, light design with a **thin, naked, metal** wire, allowing to move as close as possible to the beam, while minimizing interactions with beam particles.
- Bond the metal wire onto a support being both an **electrical insulator** and a **thermal conductor (ceramic)**.
- Keep design simple and affordable, by using a **mobile vacuum chamber**, integral with wire, which can be shifted horizontally or vertically.
- To ease fabrication, assembling and installation, split the active length (3 m) in several **independent modules**, tentatively 3, **each 1 m long**, carrying up to **130 A**.
- Each module to be mounted and aligned on a **single support** structure, which can be integrally actuated.
- Exploit experience and know-how from collimators and TCTW, particularly for actuation system ...

The Idea

- A first concept presented by A. Rossi at Impedance WG on 1st June '18.
- Initially ok with impedance, detailed analysis to follow when full design is ready.
- The initial concept posed several technological changes ... concept evolved (and still evolving ...)

Main Design Features: Wire and Insulator

- Vacuum brazed solution. Dimensions of the insulator just preliminary.
- **Mo wire** has higher electrical resistivity compared to **Cu** (factor 3), but is **better matching** ceramic **CTE** and is refractory (higher robustness, similar density).
- Diameter **can hardly be smaller than 1 mm** for **technological reasons** (regardless of electrical current). Technological validation necessary ...

Main Design Features: Housing

- Insulator with wire is mechanically clamped to a Cu housing, via controlled-torque screws

Main Design Features: Vacuum Chamber

- Water cooling channel obtained by machining the housing and welding a circuit cover.
- Cu half-shell welded to the housing.
- Stainless steel flange brazed to copper and then welded to vacuum chamber.
- Total length: ~ 1200 mm. Welded bellows with RF fingers to be foreseen at extremities.

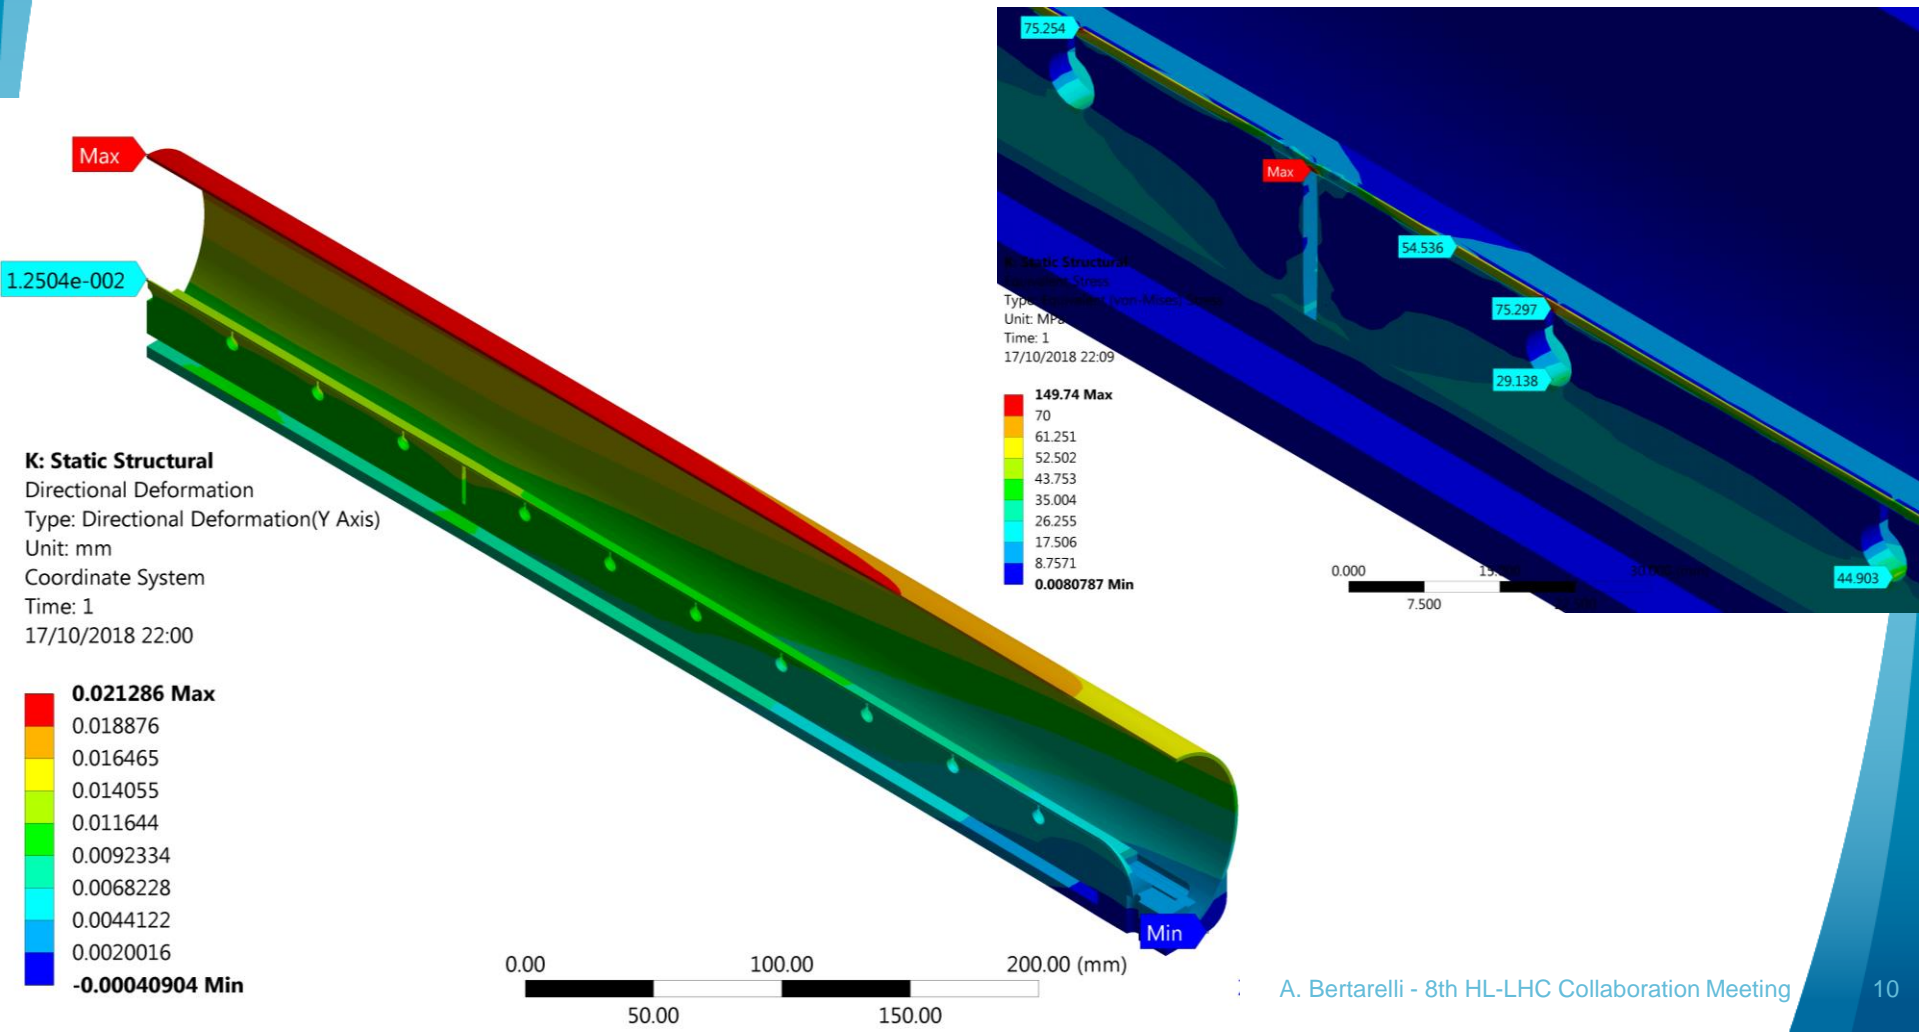

Engineering Parameters and Calculations

- With a \varnothing 1 mm wire and 133 A per module, Joule-effect power to be dissipated is ~ **0.5 kW** in case of **Cu** and ~ **1.7 kW** in case of **Mo** (reminder: no beam losses included)
- Maximum temperature ~ **50 °C** in case of Cu, and ~ **100 °C** in case of Mo
- Water coolant circulating at ~ **3 m/s**

Engineering Parameters and Calculations

- Thermally-induced deformations appear limited ($\sim 20 \mu\text{m}$) and stresses acceptable ($\sim 80 \text{ MPa}$ in Mo, $\sim 50 \text{ MPa}$ in AlN)

Outlook

- We are still at a brainstorming stage, exploring ideas, possibilities and specifications, concepts are evolving ...
- Favoured concept is based on a simple, affordable mobile vacuum chamber with a solid metal wire.
- No showstoppers identified (yet?) for a thin Mo (or Cu) naked wire ($\varnothing \geq 1$ mm) brazed onto a ceramic insulator.
- However, preliminary investigation **ignored several key physical and technological aspects** (e.g. beam losses, UHV aspects, RF impedance, transition feasibility, fabrication tolerances, bellows fatigue, RF fingers etc.) which should be the object of a proper design study.
- The manufacturing of a (small) demonstrator is paramount to validate the concept.

Thank you
