## Bounding the Higgs width through interference effects

*Tuesday, April 9, 2019 11:35 AM (25 minutes)*

The Higgs decay width can be constrained by exploiting interference effects of the  $pp \rightarrow H \rightarrow \gamma\gamma$  signal with the  $pp \rightarrow \gamma\gamma$  continuum background, which leads to a width-dependent shift of the Higgs mass peak. I review a study in which my collaborators and I investigate the reach of an analysis that determines the reference mass by measuring the di-photon final state at high transverse momenta, using a full particle-level prediction calculated with the Monte-Carlo event generator Sherpa. We also propose a yet more powerful technique based on a direct fit to the experimentally observable  $m_{\gamma\gamma}$  line shape.
