The background features a complex network of overlapping lines in three colors: red, blue, and green. The lines are of varying thickness and intersect at various points, creating a web-like pattern. The red lines are primarily on the left side, blue lines are more central, and green lines are on the right side. The overall effect is a dynamic and interconnected visual field.

Pileup Suppression Techniques: Looking to the Future

Jennifer Roloff
October 24, 2018

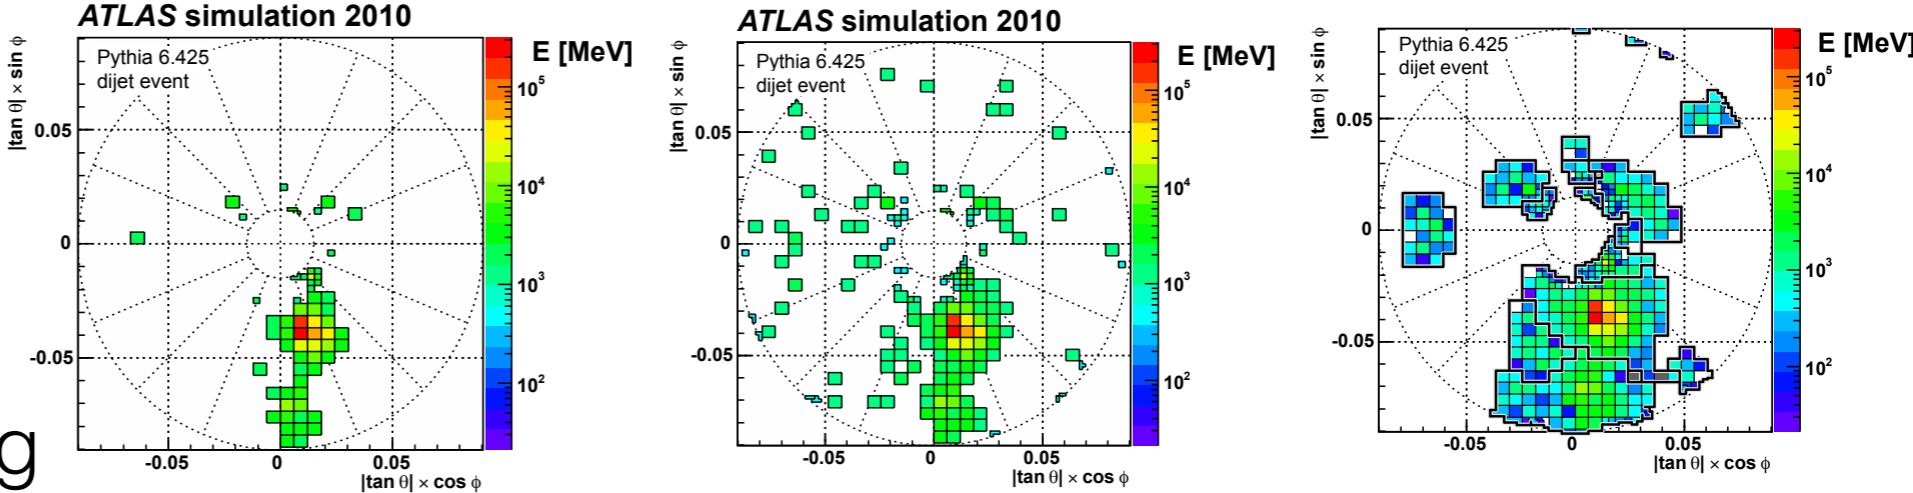

Pileup: Back to Basics

- ▶ Multiple collisions per bunch interaction at the LHC allows us to take huge amounts of data
 - ▶ These soft collisions contaminate events with hard collisions
 - ▶ Extra radiation included inside jets → worse resolution for all jet observables
 - ▶ More reconstructed objects → extra pileup jets in the event
- ▶ *Characteristics of Pileup*
 - ▶ Fairly soft collisions → low p_T particles
 - ▶ On average, fairly uniformly distributed in ϕ , and some slight dependence on η
 - ▶ For a given event, the energy density distribution is approximately Gaussian, with an average ρ , and a spread σ

How do we mitigate pileup?

▶ **Detector-level suppression**

- ▶ e.g. Noise thresholds, timing information

▶ **Constituent-level mitigation**

- ▶ e.g. CHS, PUPPI, SoftKiller, Constituent Subtraction, Voronoi Subtraction, ...

Original event

After SoftKiller

▶ **Jet-level information**

- ▶ e.g. Jet area subtraction, JVT, fJVT, Pileup Jet ID, jet cleansing

Pileup Mitigation

- ▶ What do we want in a pileup mitigation technique?
 - ▶ *Stability* — Same parameter choice works for a variety of observables over a wide range of pileup conditions
 - ▶ *Average correction* — Correction should produce the same result as zero pileup conditions on average
 - ▶ *Resolution* — Technique should result in as little worsening of resolution as possible
 - ▶ *Simplicity* — Easy to optimize parameter choices
- ▶ *To understand the future of pileup mitigation, we need to understand why current techniques work*
 - ▶ Have both event-level and local observables which can improve

Event-Level Observables

Detector Level

- ▶ Both ATLAS and CMS will be upgraded with timing detectors
 - ▶ Will cover different η regions
- ▶ Can help deal with vertex merging without requiring better vertex ID
- ▶ See [yesterday's talk by Andrea](#) for more information about this work on CMS

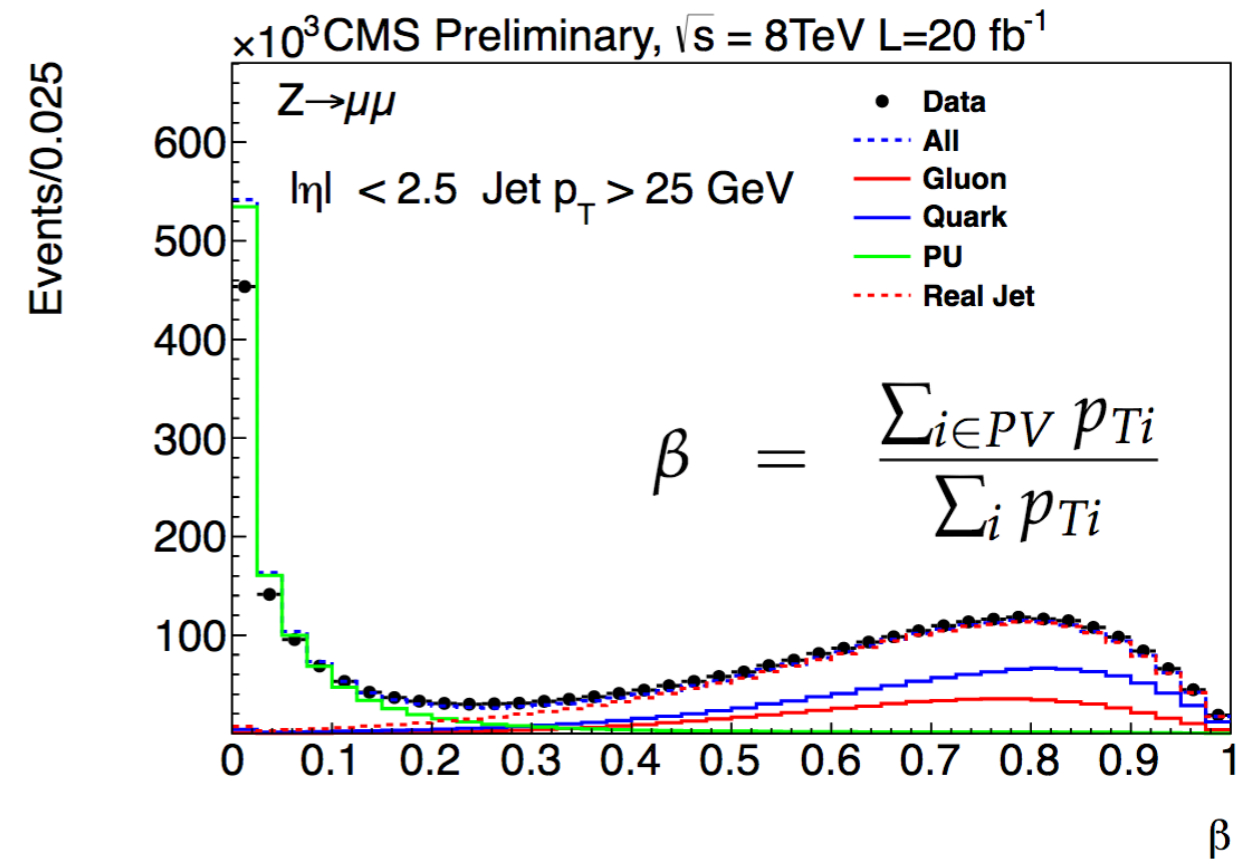

Object Level

- ▶ Event-level information can tell you how much pileup is present
 - ▶ NPV, μ , and ρ are several of the most common observables
- ▶ Median energy density ρ used for a many pileup mitigation schemes
 - ▶ The spread of ρ in an event is also of interest, though not often used
- ▶ Distribution of constituent properties for the event
- ▶ Vertex association for tracks

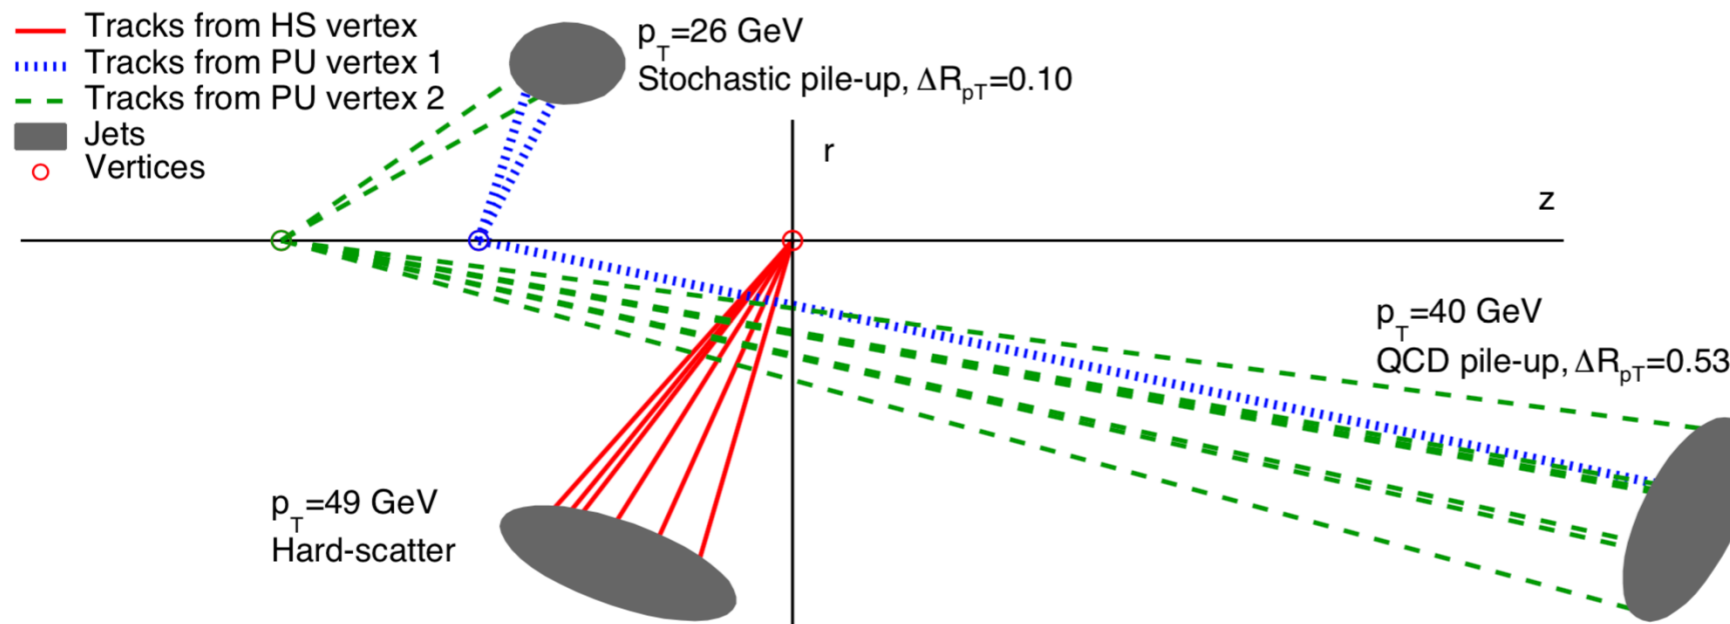

Jet Level

- ▶ Median energy density
 - ▶ Jet area subtraction
- ▶ Other jets in the event
 - ▶ Used by fJVT
- ▶ Vertex association of tracks in the jet

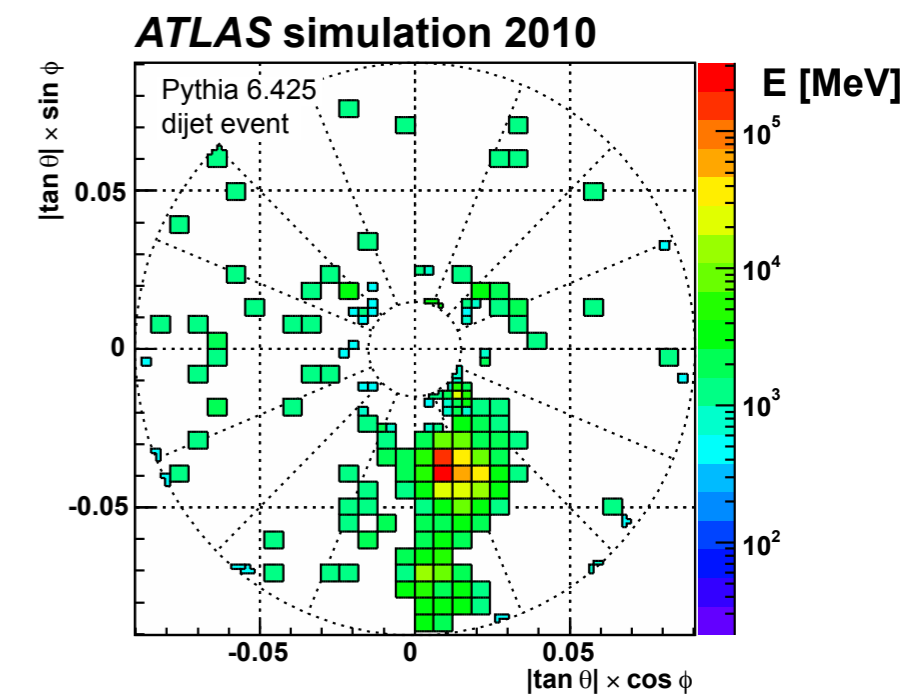

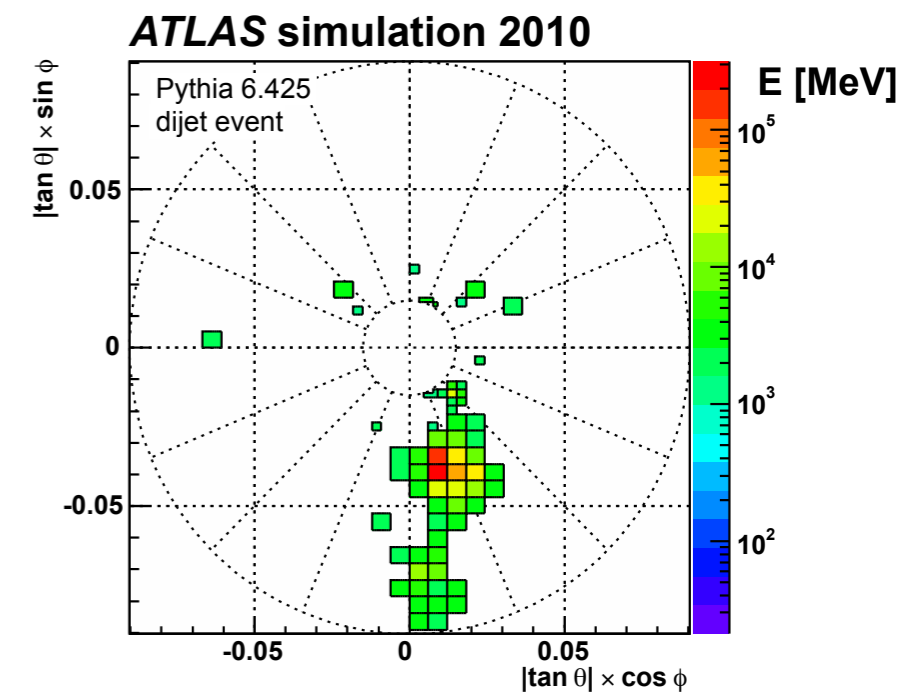

ATLAS Simulation

Local Observables

Detector Level

- ▶ **Amount of energy deposited**
 - ▶ Used to seed clusters for both ATLAS and CMS
 - ▶ Helps eliminate low-energy deposits
- ▶ **Nearby activity in the detector**
 - ▶ Used to include soft energy
- ▶ **Timing information**
 - ▶ Can be used to eliminate out-of-time pileup

Object Level

- ▶ ***Distribution of nearby constituents***

- ▶ Used by Voronoi subtraction to determine what area to assign to each constituent
- ▶ Used by PUPPI to determine α
- ▶ Used by Constituent Subtraction to determine ghost association

- ▶ ***p_T of constituents***

- ▶ Used by PUPPI to determine α
- ▶ Indirectly used by Constituent Subtraction to determine ghost subtraction

- ▶ ***Local energy density***

Jet Level

- ▶ **Area of jet**
 - ▶ Used in jet area subtraction
- ▶ **Jet width**
 - ▶ Used by fJVT
- ▶ **Jet timing**
 - ▶ Lots of different jet characteristics which can be used to discriminate between HS and PU

A Couple Examples

Case Study: Constituent Subtraction

- ▶ Calculate the median energy density ρ
- ▶ Add low- p_T ghosts to the event such that the energy density of ghosts is the same as the median energy density
- ▶ Cluster ghosts and constituents together using ΔR matching
 - ▶ Only match up to some maximum ΔR
 - ▶ Subtract off the ghost p_T from the matched constituent
- ▶ Once a constituent has zero p_T , it won't be matched to more ghosts

Constituent Subtraction

Whole event before correction

Whole event after correction

Case Study: Constituent Subtraction

- ▶ ρ changes as a function of rapidity
 - ▶ Introduced rapidity dependence in ghost momentum
- ▶ ρ fluctuates across the event
 - ▶ This means that we are under-subtracting in regions which fluctuate up
 - ▶ Could change radius parameter ΔR_{\max} , but this leads to over-subtraction in jets
 - ▶ Iterative CS redistributes the remaining p_T to a set of new ghosts
 - ▶ Allows for additional subtraction in regions with energy density above ρ without overly biasing jets

Case Study: PUPPI

- ▶ PUPPI uses a local variable α to signify how HS- or PU-like a constituent is

$$\alpha_i = \log \sum_{j \in \text{event}} \xi_{ij} \times \Theta(R_{\min} \leq \Delta R_{ij} \leq R_0)$$

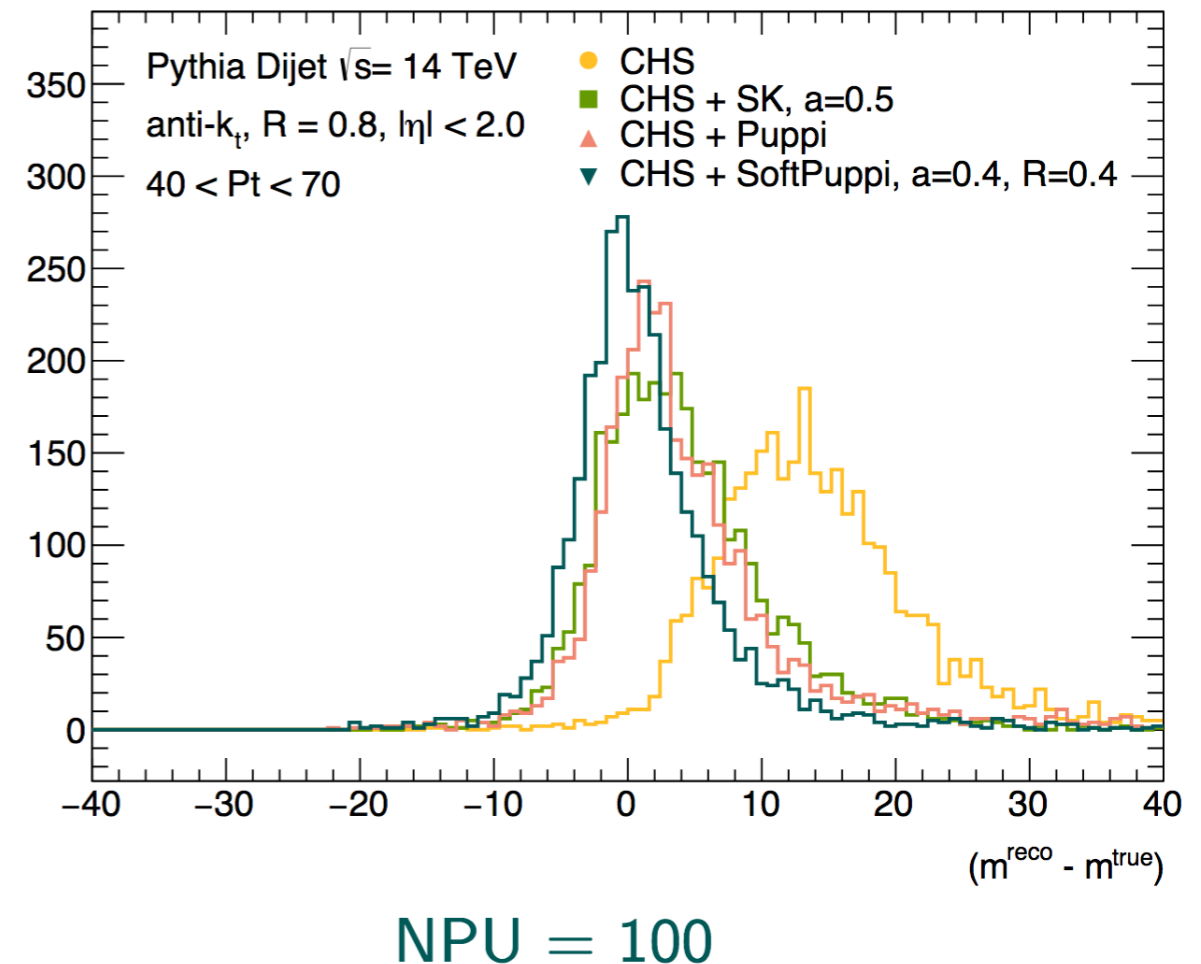

$$\text{where } \xi_{ij} = \frac{p_{Tj}}{\Delta R_{ij}}$$

- ▶ Quantifies at how close it is to hard PU or HS activity
- ▶ Uses the distribution of α for charged PU in that event to determine the weighting for the neutral constituents in the event
- ▶ Apply an NPV-dependent p_T cut to the constituents
 - ▶ Different treatment needed in regions with or without tracking
 - ▶ In total, have somewhere around 6+ parameters to optimize

Case Study: PUPPI

- ▶ PUPPI has lots of tunable parameters
 - ▶ Can use SoftKiller instead to determine p_T cut \rightarrow cuts down parameters significantly
- ▶ Many other possible improvements to the α metric as well
 - ▶ Currently only considers relationship to HS constituents
 - ▶ Why not also include information about PU vertices?
 - ▶ Could also incorporate other pileup information into the metric

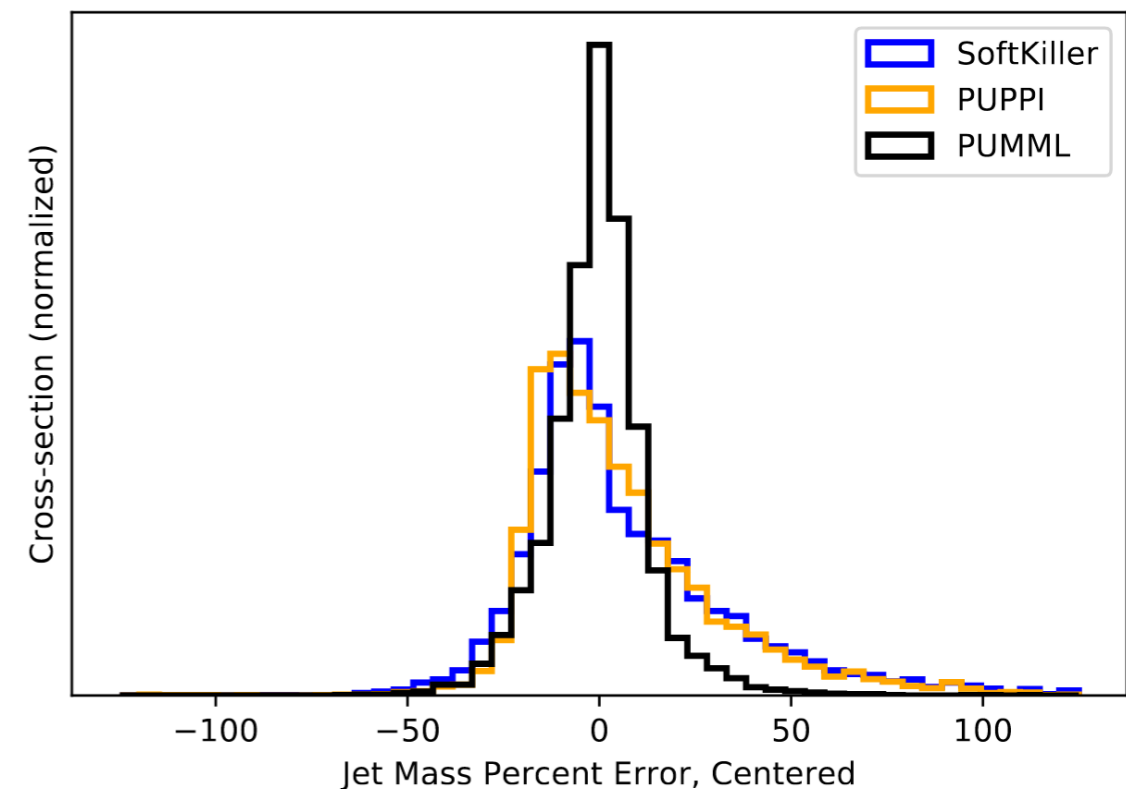

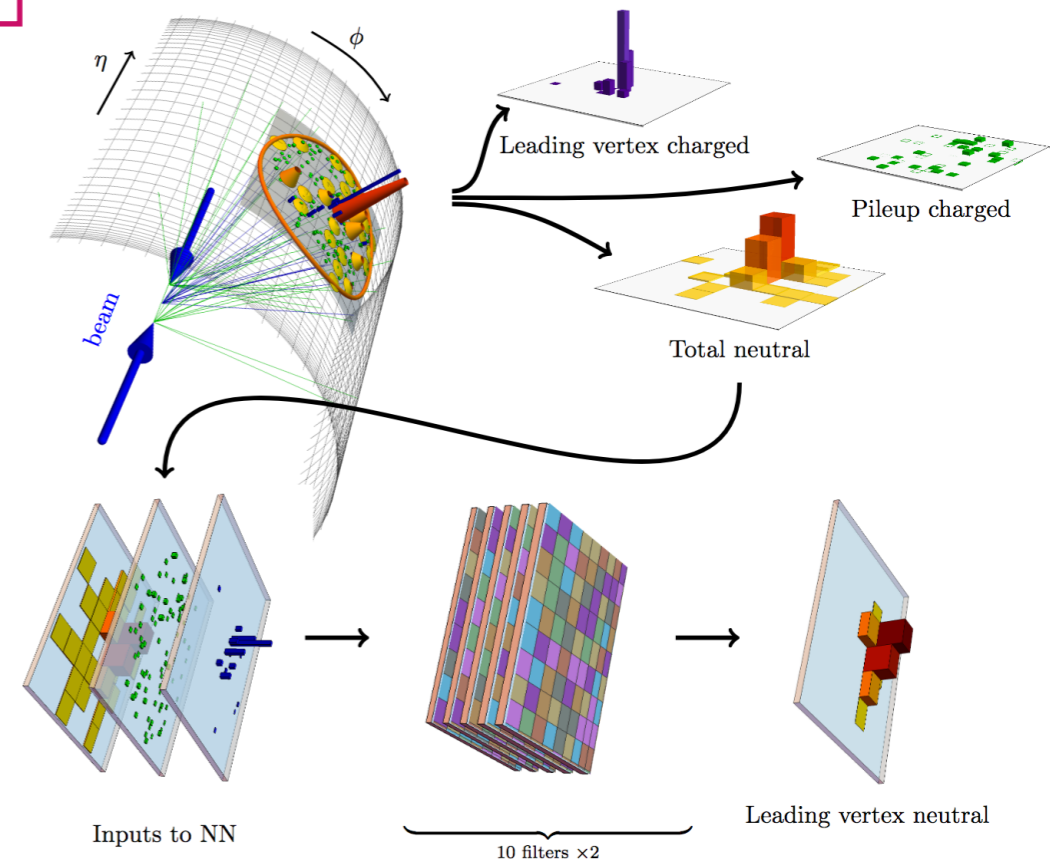

Bringing it all together: Machine Learning

- ▶ Machine learning techniques can help tie all of these ideas together
 - ▶ Need to give relevant information to deep learning algorithms in order to make use of them
- ▶ Challenges: what is the best way to use all relevant information?

Case Study: PUMML

- ▶ PUMML: **P**ile**U**p **M**itigation with **M**achine **L**earning
 - ▶ Uses a convolutional neural network with a jet image to determine what to subtract
- ▶ Jet images indirectly contain information about several pileup-related observables
 - ▶ Encodes charged HS, charged PU, and neutral activity separately
 - ▶ p_T of constituents \rightarrow can eliminate low p_T pileup constituents
 - ▶ Density of constituents \rightarrow can reduce non-collinear emissions
- ▶ Still more information that could be included
 - ▶ Event-level information

Summary

- ▶ ATLAS and CMS are both using a variety of techniques to deal with pileup
- ▶ Current techniques can be improved in a few different ways
 - ▶ *Encoding information differently* — what are the best, most concise ways of representing the information we have?
 - ▶ Including *more pileup-sensitive observables* in current algorithms
 - ▶ Creating *new observables* which are sensitive to pileup
- ▶ *Machine learning* can help bring together information from a variety of sources
 - ▶ Still a variety of things to understand about how to do this best
 - ▶ How do we best represent our jets and events?

Backup

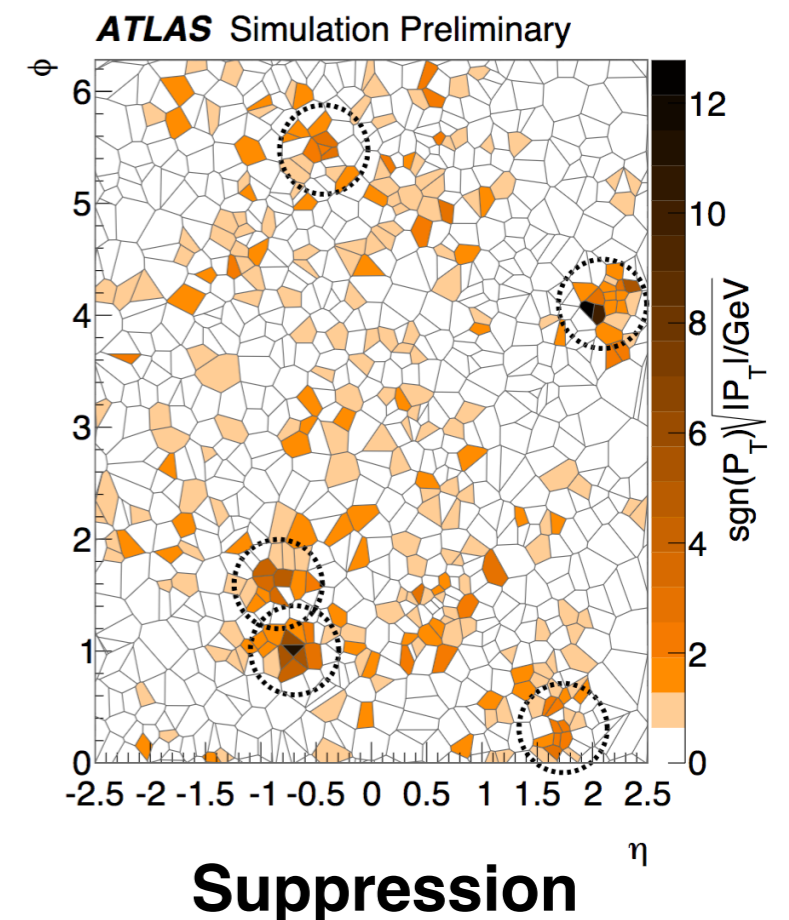

Pileup Mitigation: SoftKiller

- ▶ Determines an event-by-event p_T cut for constituents
 - ▶ Should apply either Voronoi Subtraction or Constituent Subtraction first
- ▶ Makes a grid, finds p_T cut where half of grid cells are empty afterwards
 - ▶ Makes the median energy density approximately zero

Voronoi Subtraction

- Voronoi subtraction is a type of constituent-level pileup mitigation which uses the **median energy density** (ρ) and the **Voronoi area** to reweight constituents
 - Voronoi area is the area of points in η - ϕ space which are closer to a constituent than any other
- Voronoi subtraction will leave some constituents with negative p_T — use **Voronoi suppression**, which discards any constituents with negative p_T

Pileup Mitigation: Constituent Subtraction

- ▶ Constituent-level pileup mitigation technique which *rescales* the constituent 4-momentum
- ▶ Adds ghosts evenly throughout an event with p_T density equal to the median energy density ρ
- ▶ Ghosts matched to constituents, and the ghost p_T is subtracted off
 - ▶ Only matched within some maximum ΔR of the constituent
- ▶ After subtraction, the median energy density should be approximately zero

Whole event before correction

Whole event after correction
