Charged-particle production as function of event multiplicity in ALICE

Tuesday, 2 June 2020 07:30 (1h 20m)

The ALICE experiment at the LHC is designed to investigate the properties of the Quark-Gluon Plasma by studying high-energy A–A collisions. Medium effects like parton energy loss can be examined by measuring the production of charged particles at high transverse momentum ($p_T$). In particular, the correlation between $p_T$ spectra and event multiplicity of charged particles can give a handle on the different production mechanisms of charged particles.

In this poster, we report on charged-particle $p_T$ spectra as a function of the event multiplicity in pp collisions at $\sqrt{s} = 2.76$, 5.02, 7 and 13 TeV as well as in p-Pb and Pb-Pb collisions at $\sqrt{s_{NN}} = 5.02$ TeV to study the energy and system size dependence. By comparing to QCD-inspired models, this measurement can help in understanding the event multiplicity dependence of charged-particle production mechanism.
