

Motivation for crystal collimation for HL-LHC

R. Bruce on behalf of WP5

Material from A. Abramov, C. Bahamonde, N. Fuster Martinez, A. Lechner, A. Mereghetti, D. Mirarchi, S. Redaelli

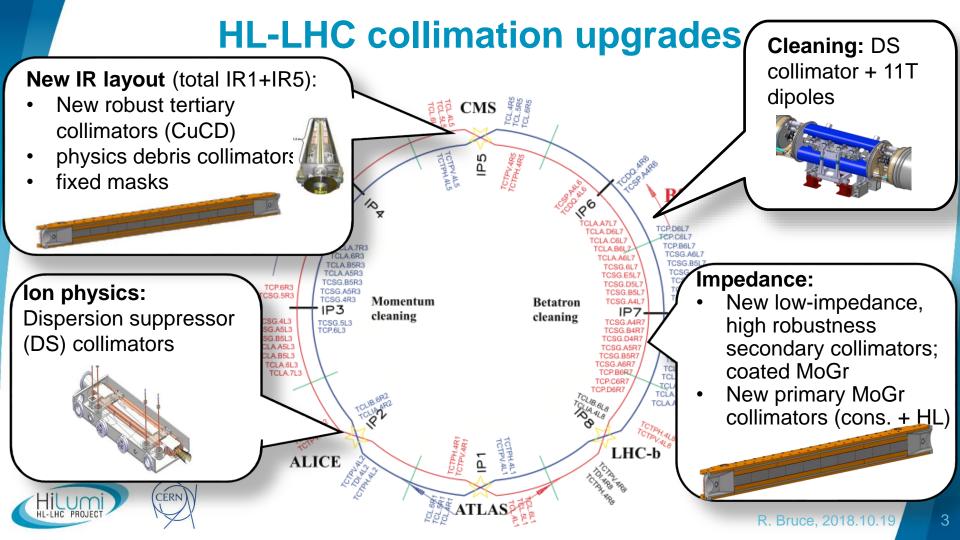

2018.10.19

Outline

- HL-LHC collimation baseline upgrades for betatron cleaning
- Cleaning efficiency with Run 3 and Run 4 layouts for protons and Pb ions
- Outcome of energy deposition studies
- Performance concerns for Pb ion collimation

Baseline collimation upgrades

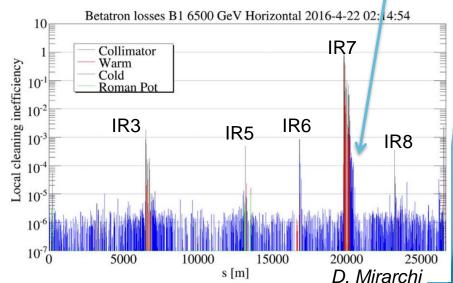

- LS2 collimation upgrades (per beam)
 - 2 low-impedance primary collimators (TCPPM) in IR7
 - 4 low-impedance secondaries (TCSPM) in IR7
 - 1 dispersion suppressor collimator (TCLD) downstream of IR7
 - 1 dispersion suppressor collimator (TCLD) downstream of IR2
- LS₃ collimation upgrades (per beam)
 - 7 low-impedance secondaries (TCSPM)
 - 6 new tertiary collimators (TCTPM), 2 re-used (TCTPV)
 - 4 physics debris collimators (TCLP)
 - 6 fixed masks (TCLM)

em should safely dispose proton losses

Reminder: Why do we need a cleaning upgrade?

- Collimation system should safely dispose of unavoidable losses
- Small leakage of particles out of collimation system (cleaning inefficiency)
 - Main bottleneck: IR7 dispersion suppressor
 - Quench limit and inefficiency limit allowed loss rate
 - For given beam lifetime, limit on total intensity

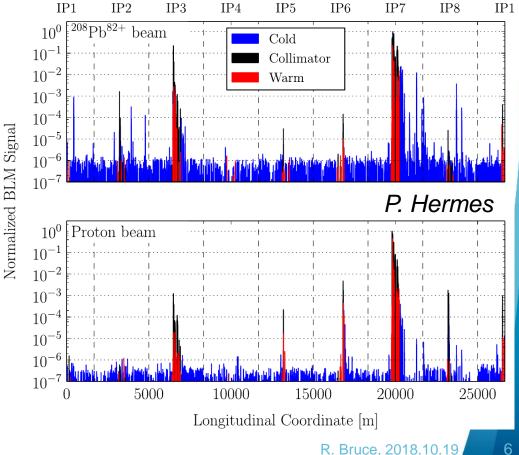

Comparison of Pb ions and protons

For both species, limit is in the IR7 DS

- Factor ~100 worse cleaning inefficiency for ions
 - lon cleaning is critical, in spite of stored energy being much lower than for protons

How to improve for HL-LHC

- Risk to be limited in intensity reach if nothing is done
- IR7 DS is the bottleneck, due to off-energy particles (or ion fragments) scattered out of primary collimator

Collimators

- Solution: introduce extra collimators, TCLDs, in dispersion suppressor
 - Make space by replacing a standard dipoles by two shorter 11T dipole, with TCLD in between
- Present HL baseline: install 1 IR7 TCLD per beam in LS₂
 - 2 TCLDs per side also studied (previous baseline would give best performance)
 - Excluded to have more 11T units available in LS2

TCLD

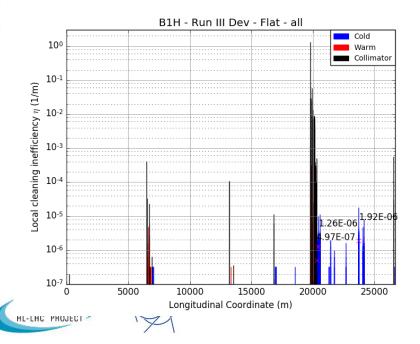

Performance with upgraded layouts

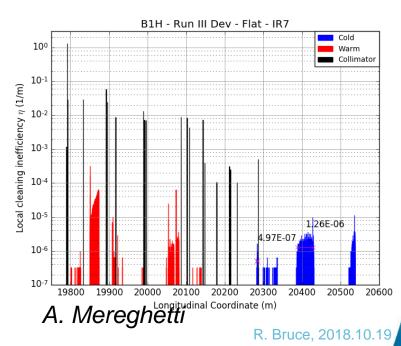

- Collimation cleaning inefficiency studied in tracking simulations
 - Using SixTrack-FLUKA coupling
 - Run 3 and Run 4 (HL-LHC) studied
 - See talks A. Mereghetti and N. Fuster Martinez on Tuesday

Proton cleaning – flat optics for Run 3

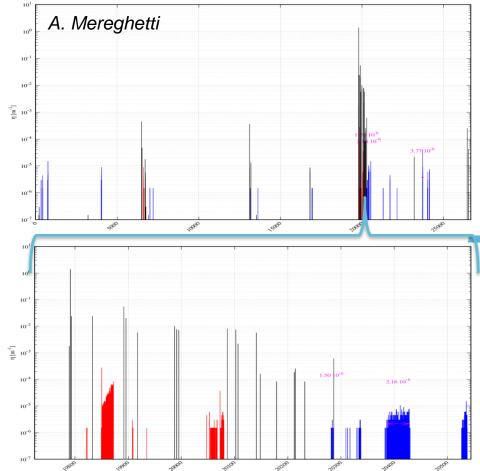

- Assumed similar collimator settings as 2018, β *= (50cm/15cm)
- TCLD shields well the first loss cluster

Proton cleaning – HL-LHC v1.3

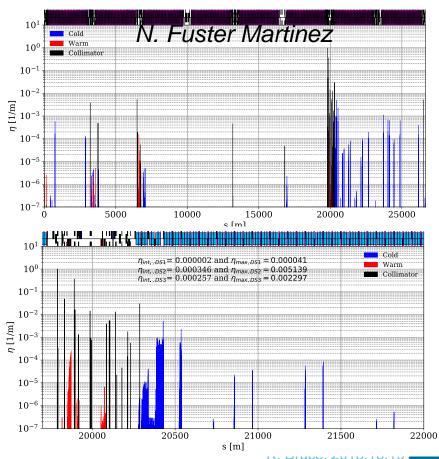

- Similar performance for HL-LHC v1.3, β*=15 cm
 - Slightly more open collimator settings assumed than for Run 3

Pb ion cleaning – Run 3 layout

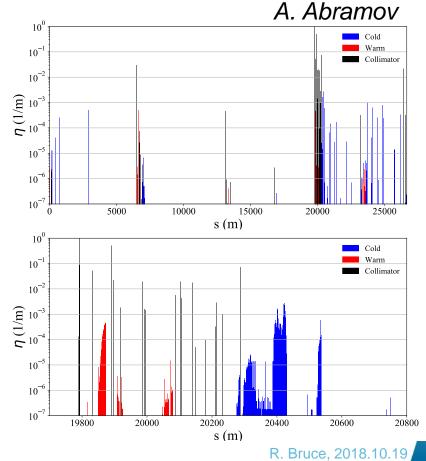

- Assuming the 2018 ion optics, but with the Run 3 layout
 - including TCLD and the foreseen low-impedance collimators

Pb ion cleaning – HL-LHC v1.2

- Using optics HL-LHC v1.2 ion version for v1.4 under development (R. de Maria)
- TCLD shields well the first loss cluster, but the second one remains almost unchanged
- Pb ion cleaning remains a factor ~100 worse than proton cleaning

Energy deposition studies

- Tracking simulations show the lost primary beam protons
- FLUKA energy deposition studies needed to assess the risk to quench magnets (C. Bahamonde, A. Lechner)
 - Using output from tracking as starting conditions
 - See talk C. Bahamonde in Wednesday's session
- Output: energy deposition, per lost primary proton or Pb ion on the collimation system
 - scaled up by factor 3 to compensate discrepancy with LHC measurement

Normalization of energy deposition studies

- Normalizing loss power to the two design loss scenarios:
 - 12 minute beam lifetime, to be sustained for 10 s
 - I h beam lifetime, to be sustained "infinitely"
- Assumptions on beam conditions for HL-LHC

	# bunches	# particles/bunch	Loss rate 12 min.	Loss rate 1 h.	Loss power (12 min.)	Loss power (1 h)
Protons	2760	2.3e11	8.81e11 p/s	1.76e11 p/s	988 kW	198 kW
Pb lons	1248	2.1e8	3.64e8 Pb/s	7.28e7 Pb/s	33 kW	6.7 kW

Outcome of energy deposition study

- Numbers shown already in Madrid 2017 (see talk C. Bahamonde)
- The installation of the TCLD always improves the situation
- For protons, the HL-LHC baseline is solid and shows good performance
 - Some margin up to quench limit
- For Pb ions, even with the TCLD, peak energy deposition on standard dipole in cell 11 above estimated quench limit
- Unless typical beam lifetime drops stay significantly above 12 minutes, risk for availability issues due to beam dumps on losses

Conclusions

- Baseline collimation layouts for Run 3 and Run 4 presented
- Cleaning performance with protons and Pb ions estimated through tracking studies and energy deposition
 - Collimation system meets requirements for protons
 - For Pb ions, estimated peak energy deposition is above quench limit during 12 minute lifetime drop – risk to introduce operational bottlenecks
- Other alternative means of improving cleaning efficiency for Pb ions should be investigated
 - Crystals?
