TOP MASS MEASUREMENT THROUGH RADIATIVE EVENTS

- ▶ METHOD DESCRIPTION
- ▶ ESTIMATED UNCERTAINTIES
 - ▶ THEORETICAL UNCERTAINTY : SCALE VARIATION
 - ▶ THE LUMINOSITY SPECTRUM ROLE IN THE SCALE VARIATION
 - ▶ STATISCAL UNCERTAINTY (UPDATED FOR THE NEW LUMINOSITY SCHEDULE)
 - ▶ SYSTEMATIC UNCERTAINTY : PHOTON ENERGY SCALE
 - ▶ SYSTEMATIC UNCERTAINTY : IMPERFECT SIMULATION
 - ▶ SYSTEMATIC UNCERTAINTY : PROPAGATION OF THE LUMINOSITY SPECTRUM DETERMINATION

INTRODUCTION TO THE OBSERVABLE

Complementary to the threshold scan measurement, but also in a well defined mass scheme.

Using the 380GeV run (1ab^{-1} integrated luminosity)

Well establish technique:

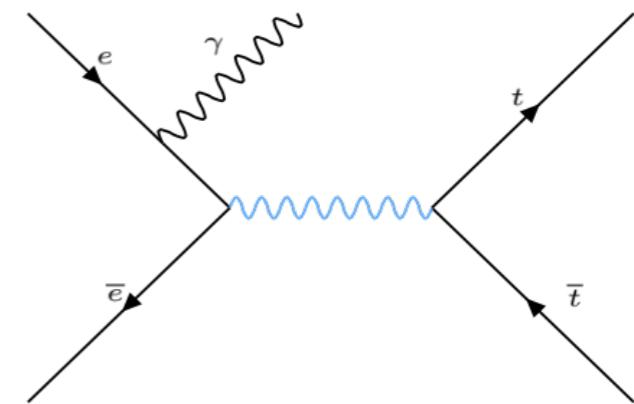

PROPOSED: [**EUR. PHYS. J. C73 \(2013\) 2438**](#)

USED BY ATLAS (@7TEV) : [**JHEP 10 \(2015\) 121**](#)

AND CMS (@8TEV): [**CMS-PAS-TOP-13-006**](#)

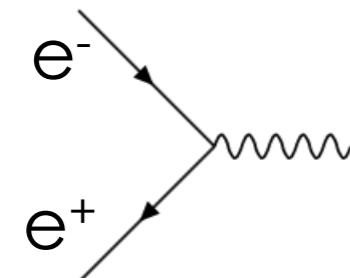

INTRODUCTION TO THE OBSERVABLE

- ▶ The idea is to measure the top-quark mass (m_t) measuring the differential cross section of the process $e^+e^- \rightarrow t\bar{t}\gamma_{\text{ISR}}$.

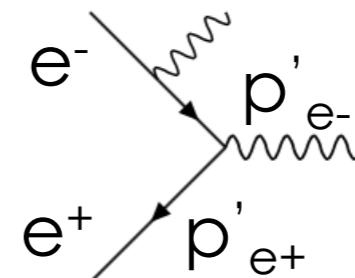

- ▶ The $t\bar{t}$ production cross section is sensitive to the center of mass energy and m_t :

$$\sigma(e^+e^- \rightarrow t\bar{t}) = f(s, m_t)$$

$$s = (p_{e^-} + p_{e^+})^2$$

$$\sigma(e^+e^- \rightarrow t\bar{t}\gamma) = f(s', m_t)$$

$$s' = (p'_{e^-} + p'_{e^+})^2$$

- ▶ The emitted γ_{ISR} reduces the available phase space for the $t\bar{t}$ production.
- ▶ Therefore the $t\bar{t}\gamma_{\text{ISR}}$ production cross section is sensitive to the emitted ISR photon energy.

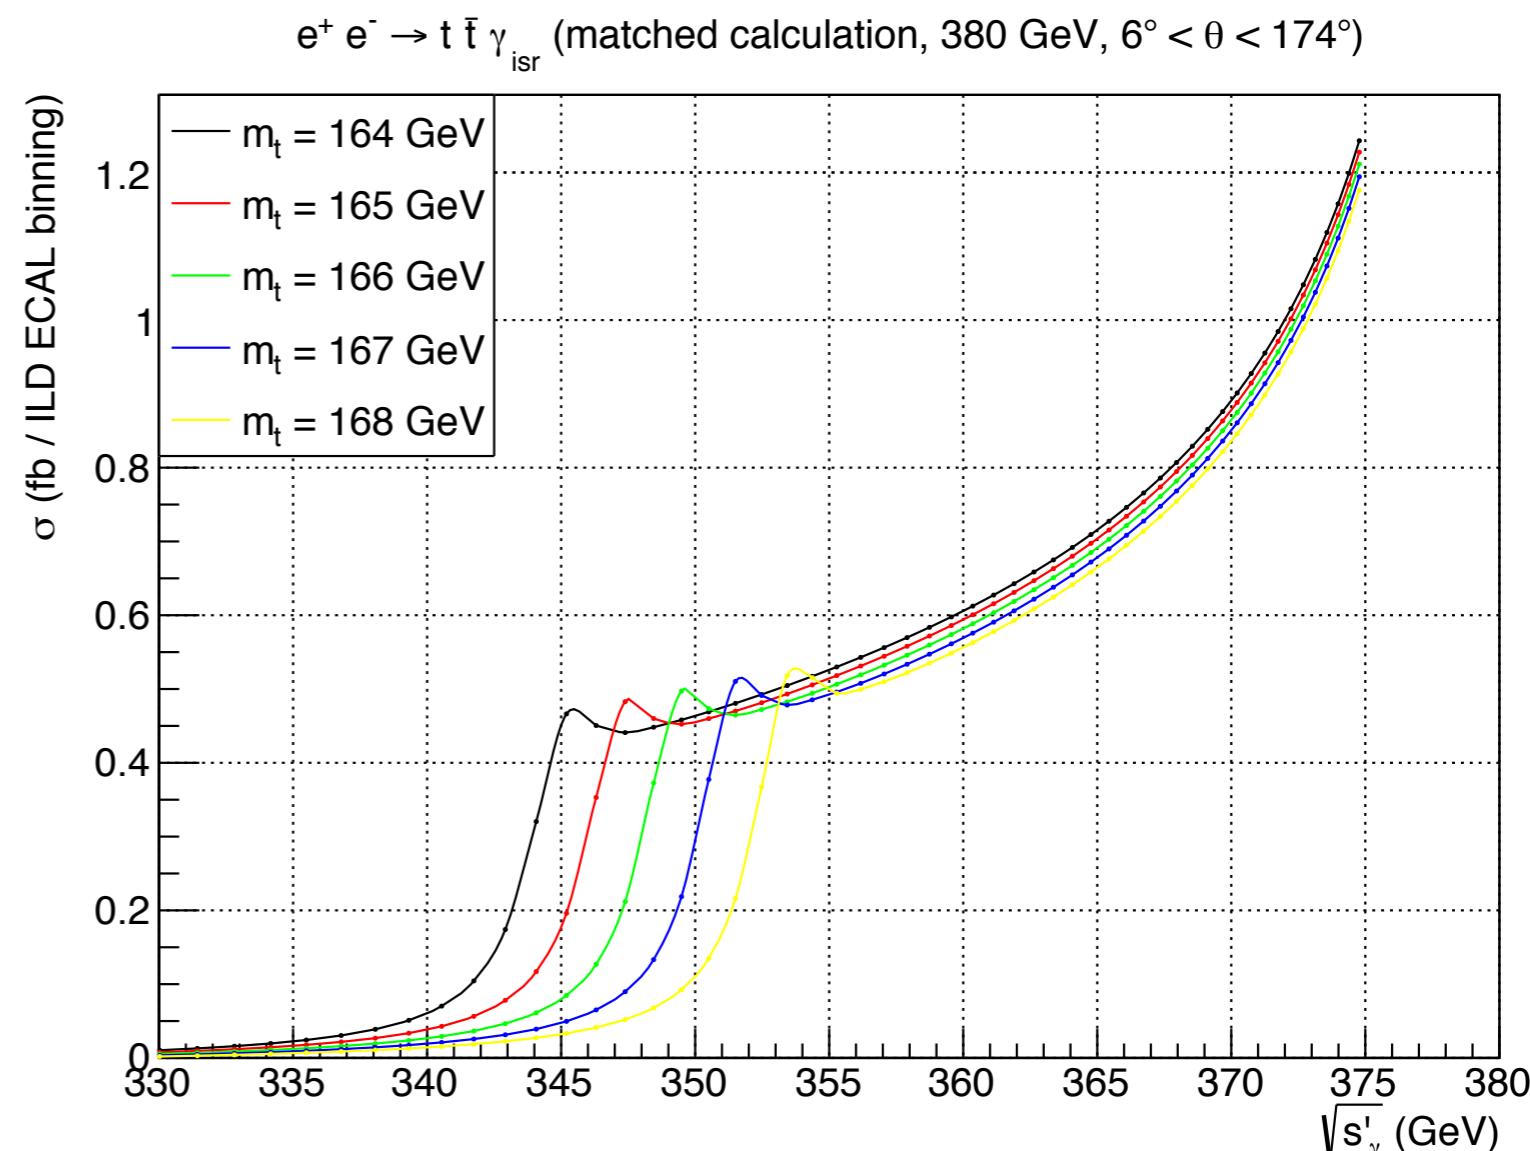

INTRODUCTION TO THE OBSERVABLE

- ▶ m_t can be measured by counting the $t\bar{t}$ events produced for a certain s' (i.e ISR energy photon):

$$s' = s \left(1 - \frac{2E_\gamma}{\sqrt{s}} \right)$$

- ▶ Our observable is the differential cross section of the $t\bar{t}$ production as a function of $\sqrt{s'}$.

- ▶ The observable is more sensitive to m_t near the top production threshold, and the dependence diminishes as $\sqrt{s'}$ grows.

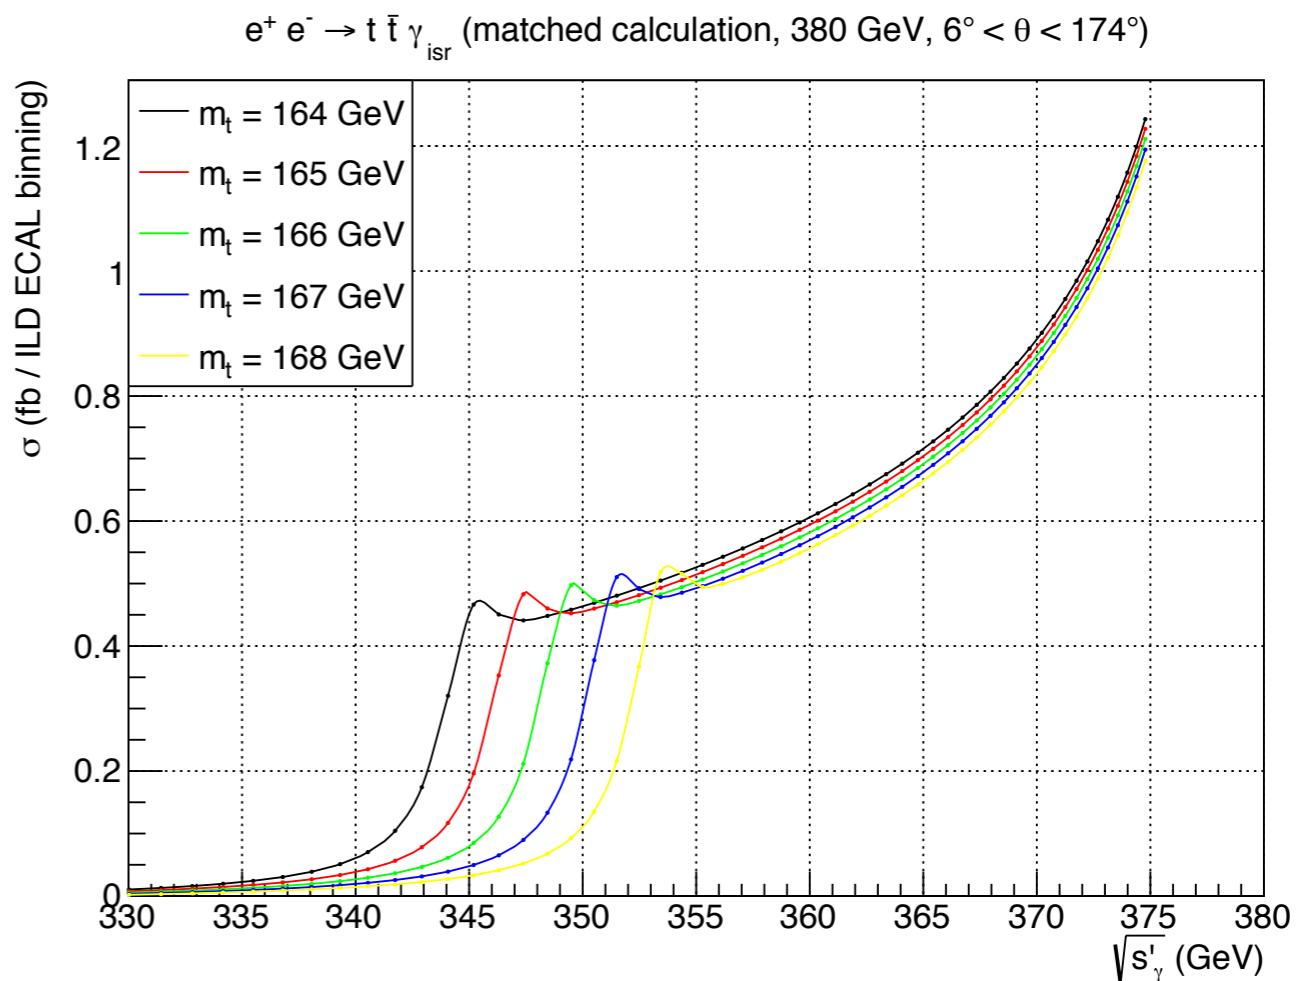

THEORETICAL MODEL: MATCHED CALCULATION

- ▶ A factorization theorem valid at $O(a_{QED})$ and to all orders in a_s (beyond perturbation theory) has been established by A. H. Hoang and V. Mateu in which the observable can be calculated analytically:

$$\sigma_{t\bar{t}\gamma_{ISR}}(m_t, s') = \sigma_{ISR}(E_\gamma) * \sigma_{t\bar{t}}(m_t, s')$$

- ▶ The model convolves the ISR calculation with the threshold - continuum matched calculation by A. H. Hoang et al.
- ▶ The model outputs the differential cross section of the $e^+ e^- \rightarrow t\bar{t}\gamma_{ISR}$ as a function of the photon energy and polar angle respect to the head-on collision, for a given top mass.
- ▶ The input mass can be chosen to be any short-distance mass scheme, in this case we chose the \overline{MS} scheme. For the calculation itself the 1S and MSR masses are used.

- ▶ For more information and details on the matched calculation:

ANGELIKA WIDL LCWS17 TALK

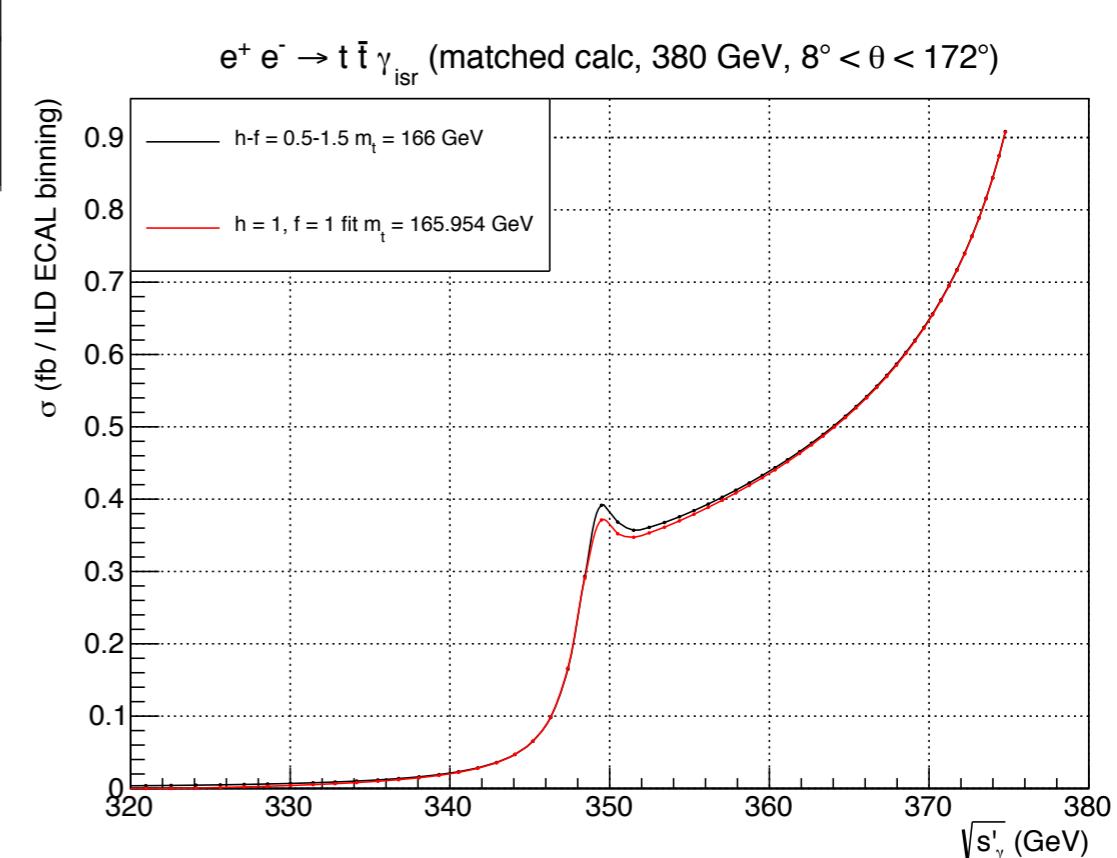

THEORETICAL MODEL UNCERTAINTY

- The main sources of uncertainty in the matched calculation come from the hard, soft and ultra soft scales in the NRQCD calculation, which can be parametrized as a function of the h and f parameters.

* results for $8^\circ < \theta < 172^\circ$

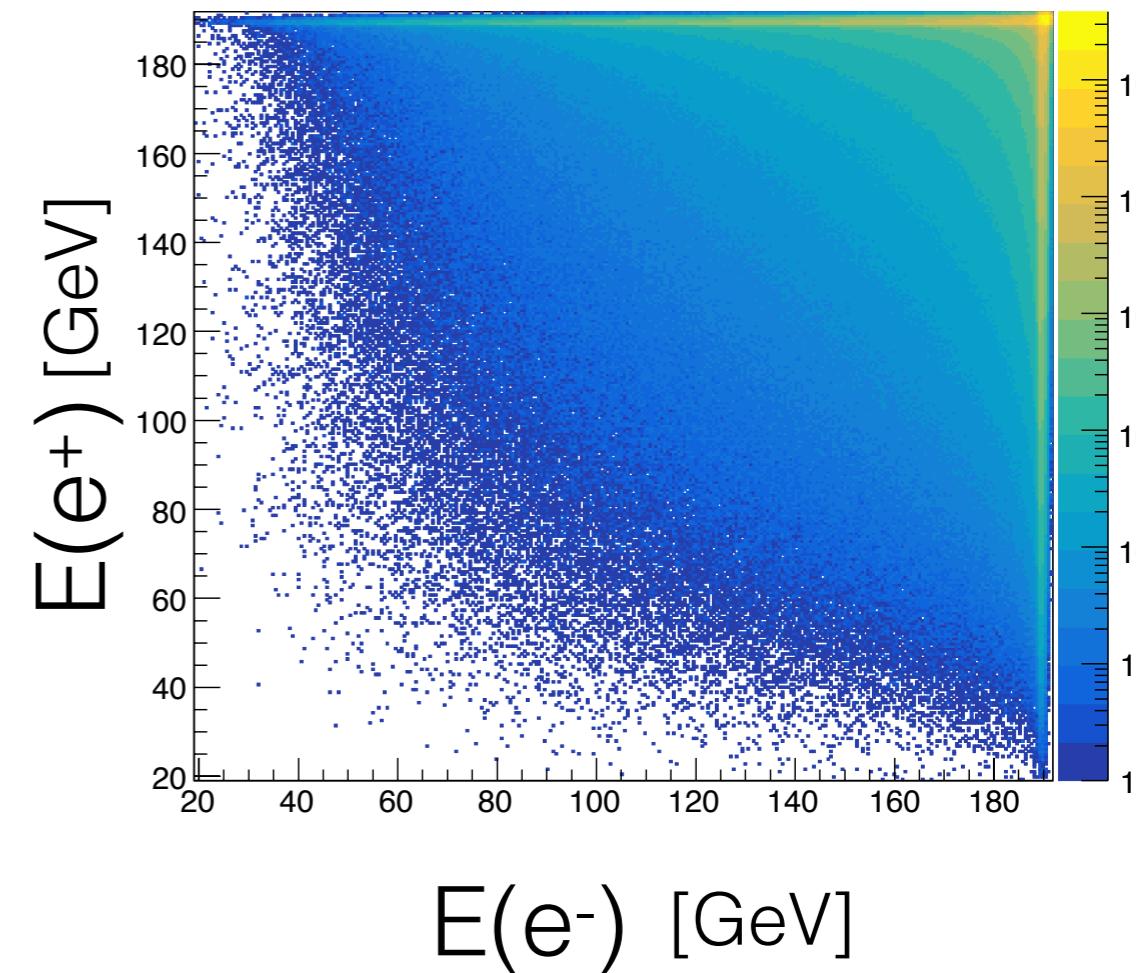

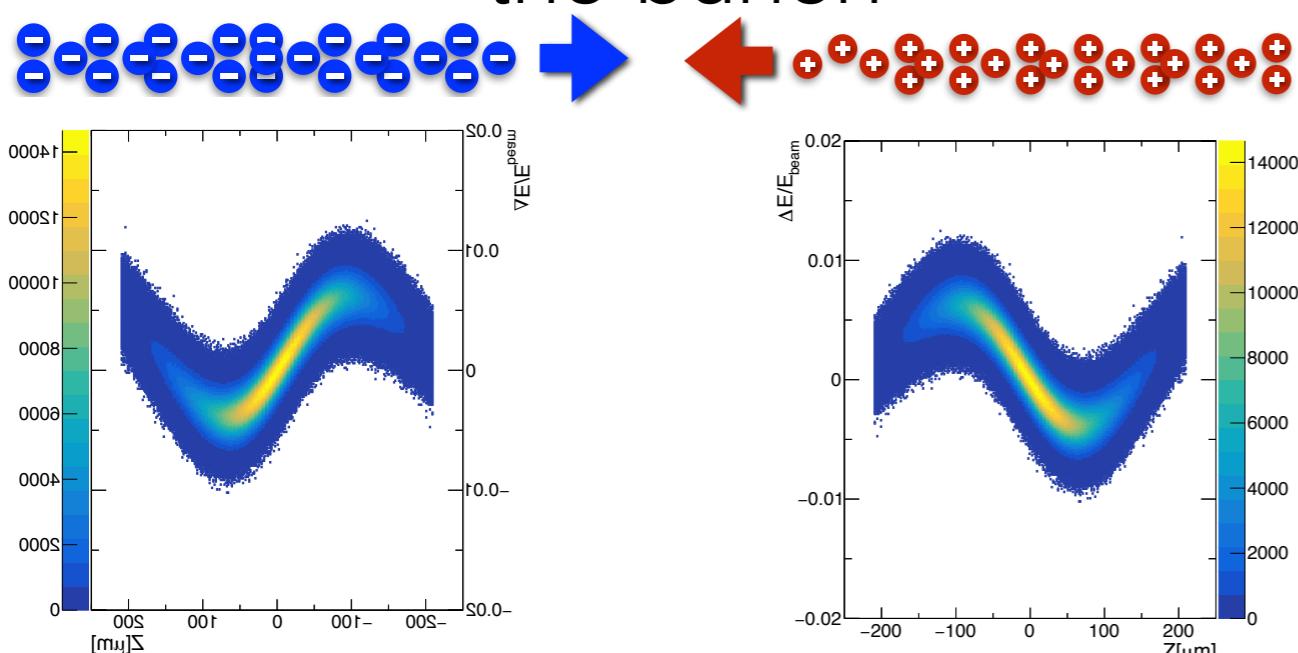

Proposed scale parameters variations (A. Hoang , M. Stahlhofen)									
h	1/2	1/2	1/2	1	1	1	2	2	2
f	2	3/2	1	1	$\sqrt{2}$	$\sqrt{(1/2)}$	1	$3/4$	$1/2$
Δm (MeV) @380 GeV	-44	-46	-43	0	-1	8	29	30	45
Δm (MeV) @500 GeV	-55	-58	-54	0	-2	12	32	34	51

- We evaluate the theoretical uncertainty by fitting the model (at 380GeV, 500 fb⁻¹) with modified scales and a given top mass (166 GeV) to the same model with the nominal scales and with the top mass as a fit parameter.
- The fits lead to an estimation of **50 MeV**
(without the luminosity spectrum)

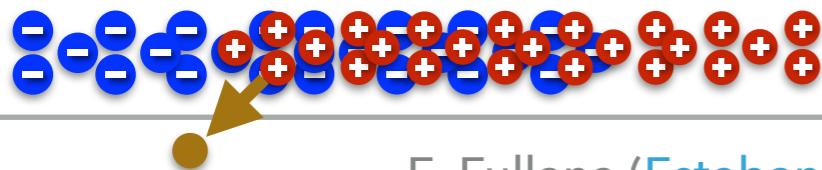

CLIC 380GeV LUMINOSITY SPECTRUM

(1) **beam energy spread** : energy distribution of the particles inside the bunch

(2) **beamstrahlung**: radiation emitted due to the interaction with the em field of the opposite bunch

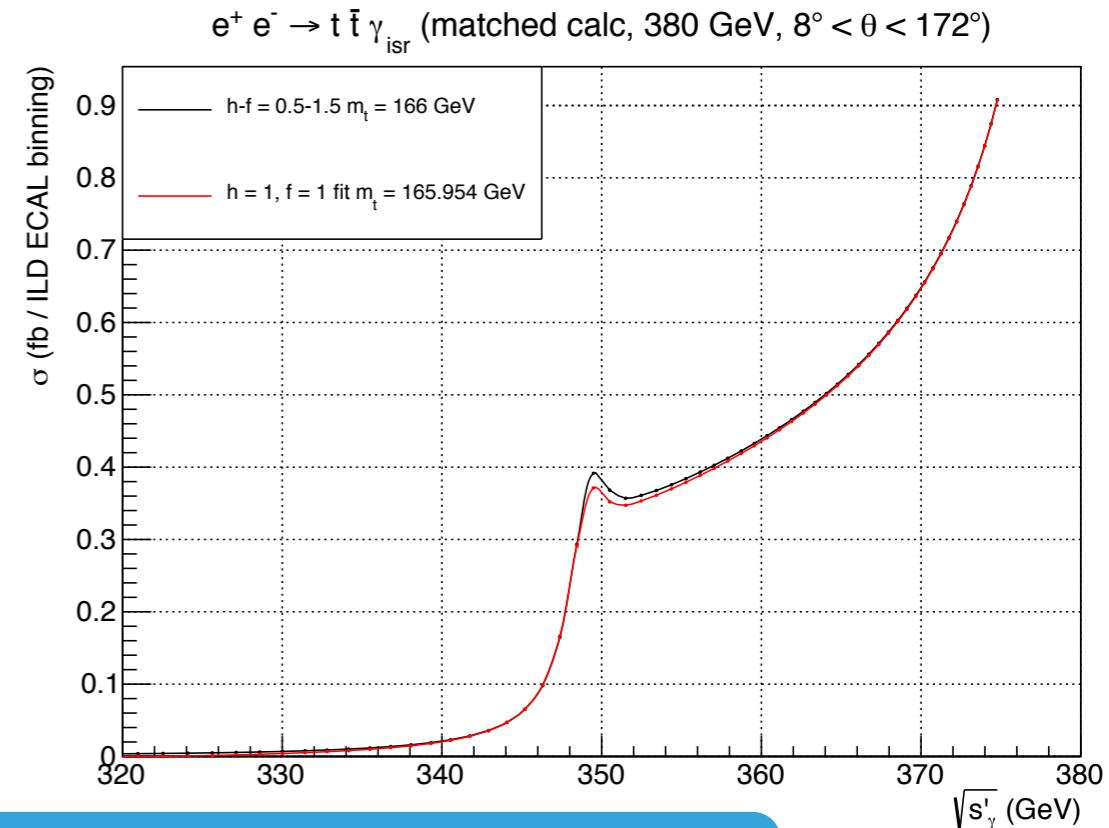

THEORETICAL MODEL UNCERTAINTY

- The main sources of uncertainty in the matched calculation come from the hard, soft and ultra soft scales in the NRQCD calculation, which can be parametrized as a function of the h and f parameters.

* results for $8^\circ < \theta < 172^\circ$

Proposed scale parameters variations (A. Hoang , M. Stahlhofen)									
h	1/2	1/2	1/2	1	1	1	2	2	2
f	2	3/2	1	1	$\sqrt{2}$	$\sqrt{(1/2)}$	1	$3/4$	$1/2$
Δm (MeV) @380 GeV	-44	-46	-43	0	-1	8	29	30	45
Δm (MeV) @500 GeV	-55	-58	-54	0	-2	12	32	34	51

- We evaluate the theoretical uncertainty by fitting the model (at 380GeV, 500 fb $^{-1}$) with modified scales and a given top mass (166 GeV) to the same model with the nominal scales and with the top mass as a fit parameter.
- The fits lead to an estimation of **50 MeV**
(without the luminosity spectrum)

SO, HOW WE ACCOUNT FOR THE LUMINOSITY SPECTRUM?

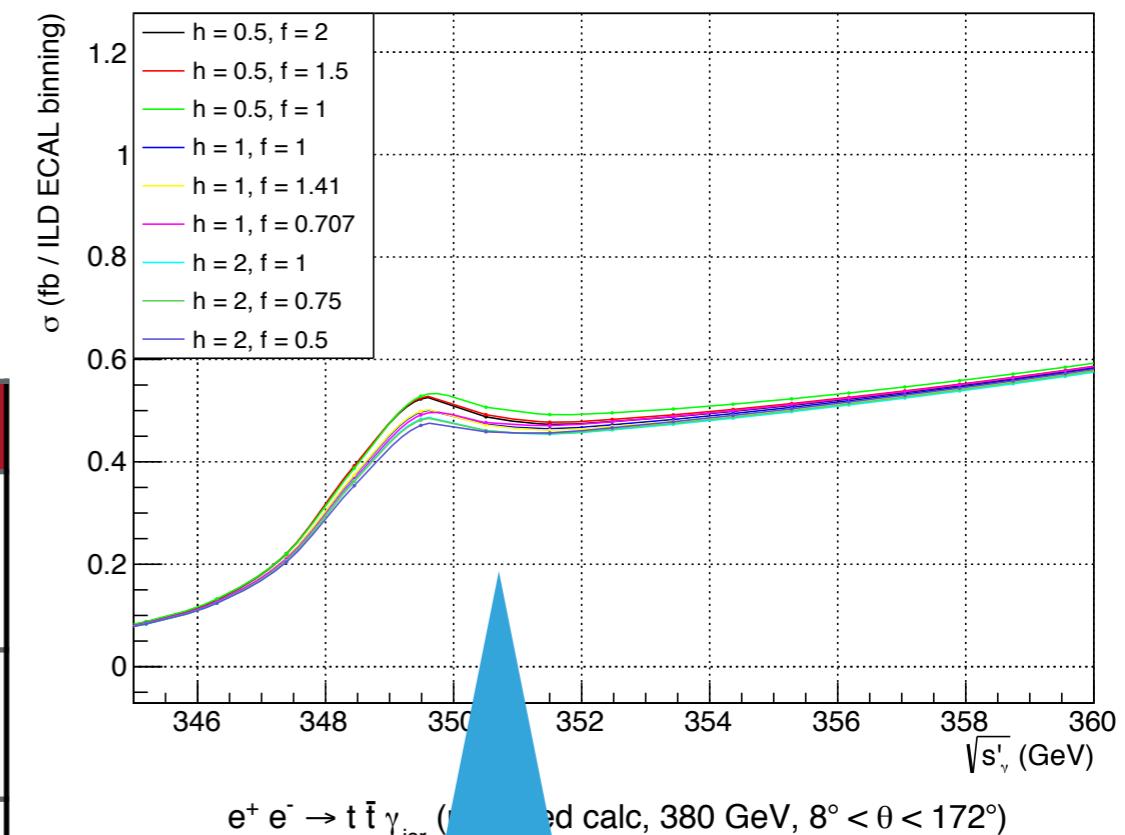

THEORETICAL MODEL UNCERTAINTY

- The main sources of uncertainty in the matched calculation come from the hard, soft and ultra soft scales in the NRQCD calculation, which can be parametrized as a function of the h and f parameters.

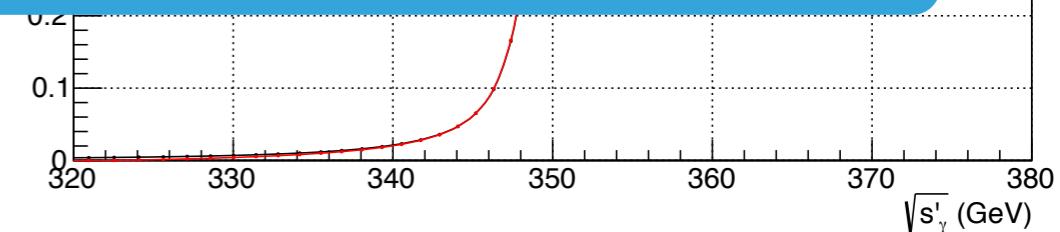

* results for $8^\circ < \theta < 172^\circ$

Proposed scale parameters variations (A. Hoang , M. Stahlhofen)									
h	1/2	1/2	1/2	1	1	1	2	2	2
f	2	3/2	1	1	$\sqrt{2}$	$\sqrt{1/2}$	1	$3/4$	$1/2$
Δm (MeV) @380 GeV	-44	-46	-43	0	-1	8	29	30	45
Δm (MeV) @500 GeV	-55								

- We evaluated the uncertainty by fitting the spectrum and recomputing the scale uncertainties, the value went to about 100 MeV, but since then we are exploring other approaches...
- The fits lead to an estimation of **50 MeV** (**without the luminosity spectrum**)

THE FIRST ATTEMPT WAS TO WEIGHT THE OBSERVABLE BY THE LUMINOSITY SPECTRUM AND RECOMPUTE THE SCALE UNCERTAINTIES, THE VALUE WENT TO ABOUT 100MEV, BUT SINCE THEN WE ARE EXPLORING OTHER APPROACHES...

THEORETICAL MODEL UNCERTAINTY

11

Proposed scale parameters variations (A. Hoang , M. Stahlhofen)									
h	1/2	1/2	1/2	1	1	1	2	2	2
f	2	3/2	1	1	$\sqrt{2}$	$\sqrt{1/2}$	1	3/4	1/2
Δm (MeV) @355 GeV	-45	-47	-41	0	-2	12	26	29	49
Δm (MeV) @360 GeV	-41	-42	-35	0	-2	11	23	26	43

Δm (MeV) @380 GeV	-43	-46	-43	0	0	8	29	30	45
Δm (MeV) @385 GeV	-45	-48	-45	0	0	8	30	31	46

* results for $10^\circ < \theta < 170^\circ$, lumi spectra unfolded

THEORETICAL MODEL UNCERTAINTY

12

WE COMPUTE THE SCALE UNCERTAINTY AT EACH COLLISION ENERGY STARTING AT 355GeV TO 385GeV AT 5GeV INTERVALS, THE UNCERTAINTY IS CONSTANT AT ~50MeV

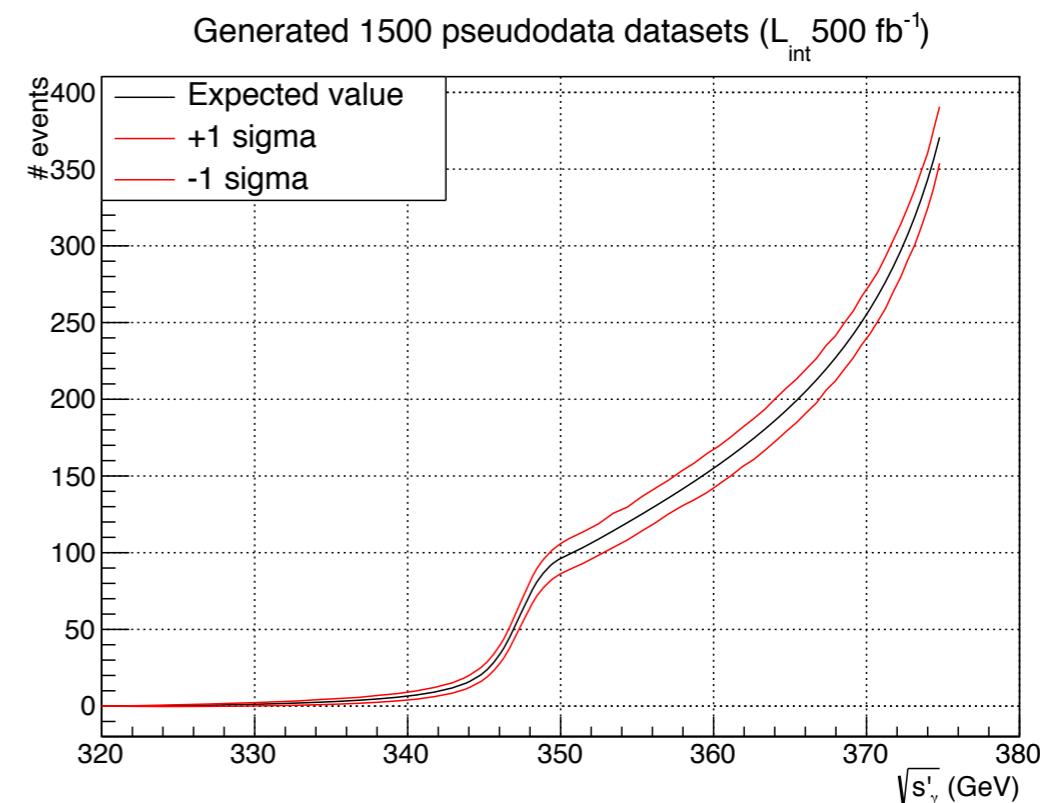

Proposed scale parameters variations (A. Hoang , M. Stahlhofen)									
h	1/2	1/2	1/2	1	1	1	2	2	2
f	2	3/2	1	1	$\sqrt{2}$	$\sqrt{1/2}$	1	3/4	1/2
Δm (MeV) @355 GeV	-45	-47	-41	0	-2	12	26	29	49
Δm (MeV) @360 GeV	-41	-42	-35	0	-2	11	23	26	43
Δm (MeV) @365 GeV	-43	-45	-40	0	-1	10	27	28	44
Δm (MeV) @370 GeV	-43	-46	-42	0	-1	9	27	28	43
Δm (MeV) @375 GeV	-44	-46	-44	0	0	9	29	30	44
Δm (MeV) @380 GeV	-43	-46	-43	0	0	8	29	30	45
Δm (MeV) @385 GeV	-45	-48	-45	0	0	8	30	31	46

* results for $10^\circ < \theta < 170^\circ$, lumi spectra unfolded

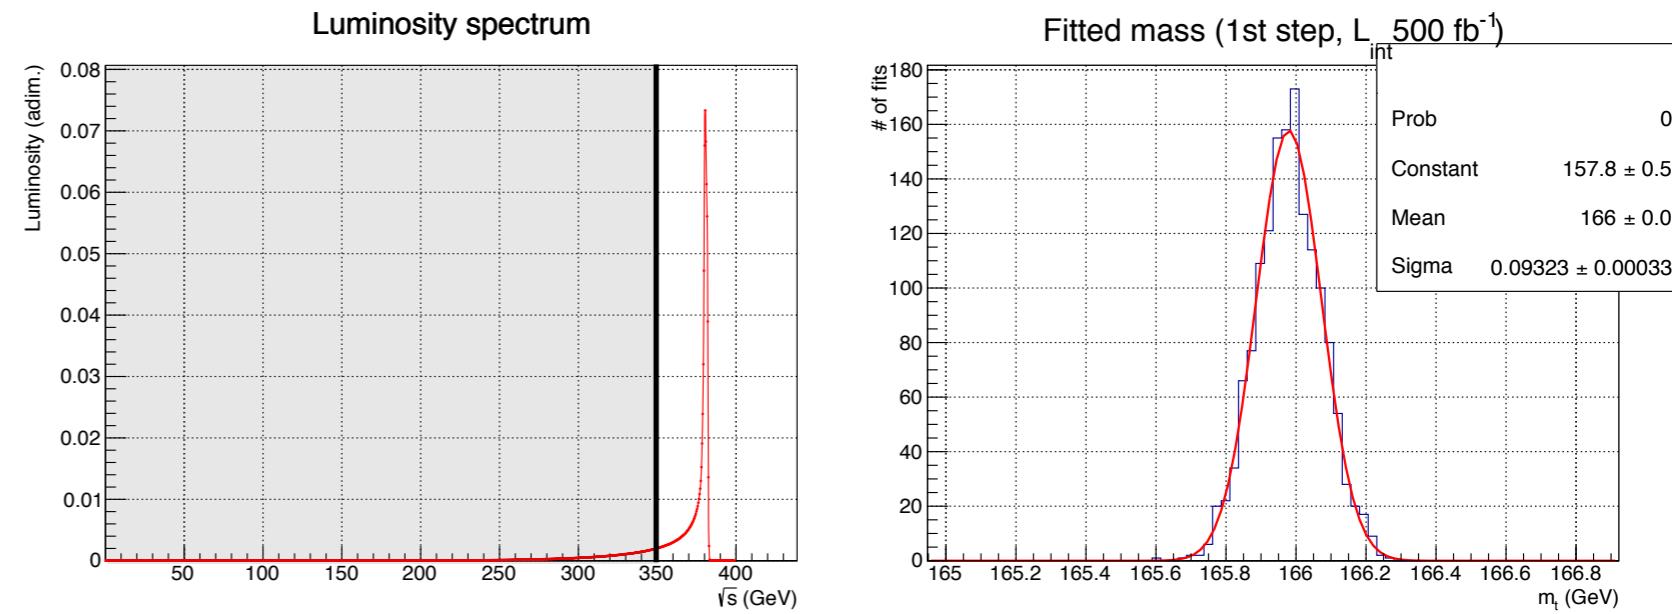

UNCERTAINTY ON THE TOP MASS (STATISTICS)

- ▶ Propagation of the statistical uncertainty into the top mass through pseudo experiments
- ▶ The Luminosity spectrum is propagated into the observable through a weighted sum
- ▶ Increment of $\sim 30\text{MeV}$ when you include the Luminosity Spectrum in the observable

	$6^\circ < \theta < 174^\circ$	$8^\circ < \theta < 172^\circ$	$10^\circ < \theta < 170^\circ$
CLIC Spectrum @ 500 fb$^{-1}$	75 MeV (50 MeV w/o)	93 MeV (60 MeV w/o.)	104 MeV (65 MeV w/o. s.)

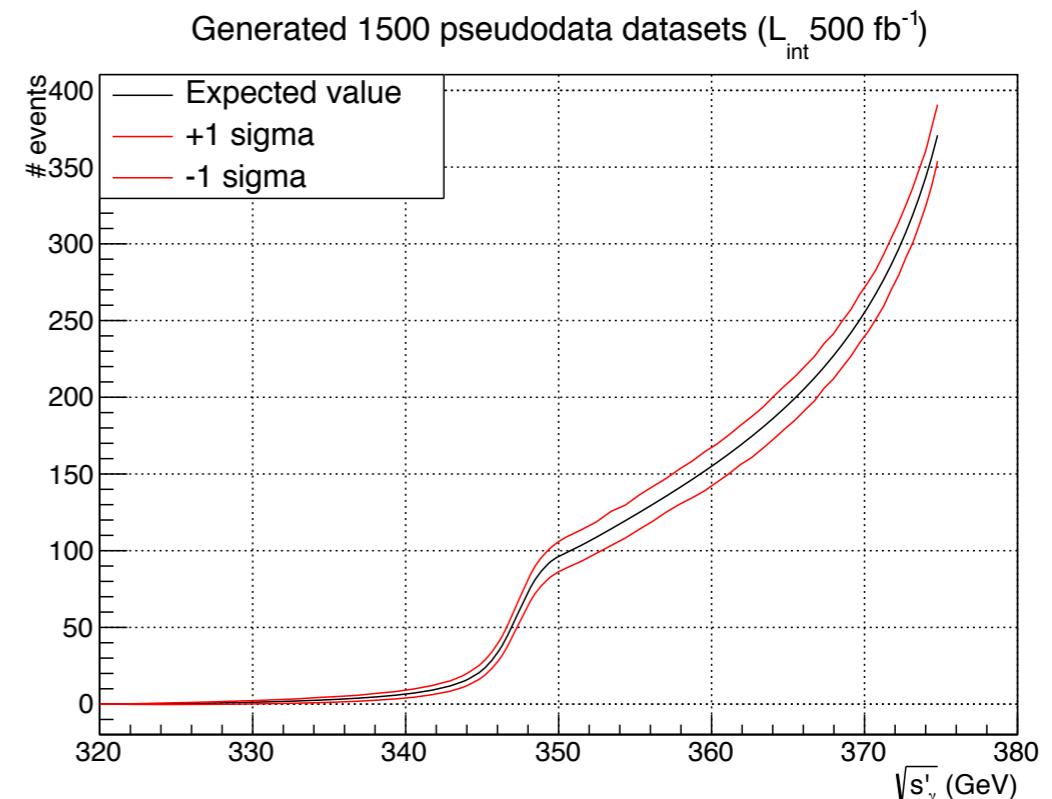

- ▶ Part of this loss in sensitivity is due to a loss of statistics ($t\bar{t}$ threshold acceptance). The other part, concerns the change in the shape due to bin migrations.
- ▶ Work in progress: by taking into account the correlations between these bins we expect to improve the sensitivity prospect.

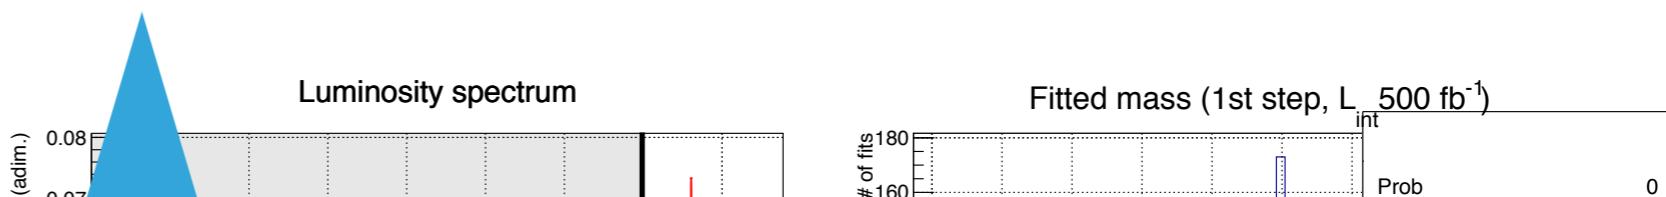

UNCERTAINTY ON THE TOP MASS (STATISTICS)

- ▶ Propagation of the statistical uncertainty into the top mass through pseudo experiments
- ▶ The Luminosity spectrum is propagated into the observable through a weighted sum
- ▶ Increment of $\sim 30\text{MeV}$ when you include the Luminosity Spectrum in the observable

	$6^\circ < \theta < 174^\circ$	$8^\circ < \theta < 172^\circ$	$10^\circ < \theta < 170^\circ$
CLIC Spectrum @ 500 fb $^{-1}$	75 MeV (50 MeV w/o)	93 MeV (60 MeV w/o.)	104 MeV (65 MeV w/o. s.)

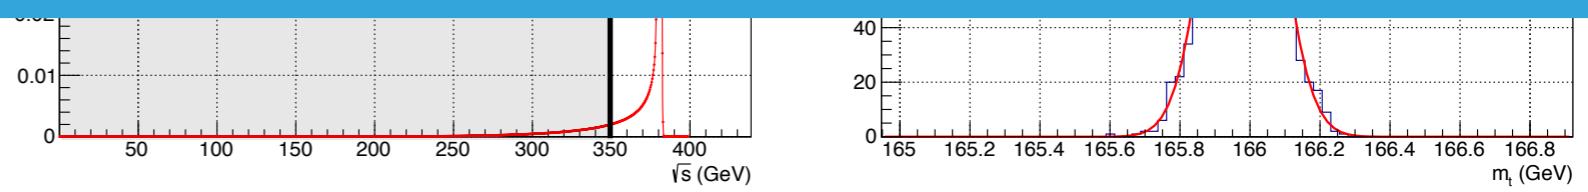

- ▶ Part of this loss in sensitivity is due to a loss of statistics ($t\bar{t}$ bar)

UPDATED TO 71.3 MeV WITH THE NEW LUMINOSITY SCHEDULE (TOTAL @ 380 GeV 1 ab $^{-1}$)

- ▶ work in progress: by taking into account the correlations between these bins we expect to improve the sensitivity prospect.

PROPAGATION OF THE UNCERTAINTY ON THE LUMINOSITY SPECTRUM INTO THE TOP MASS

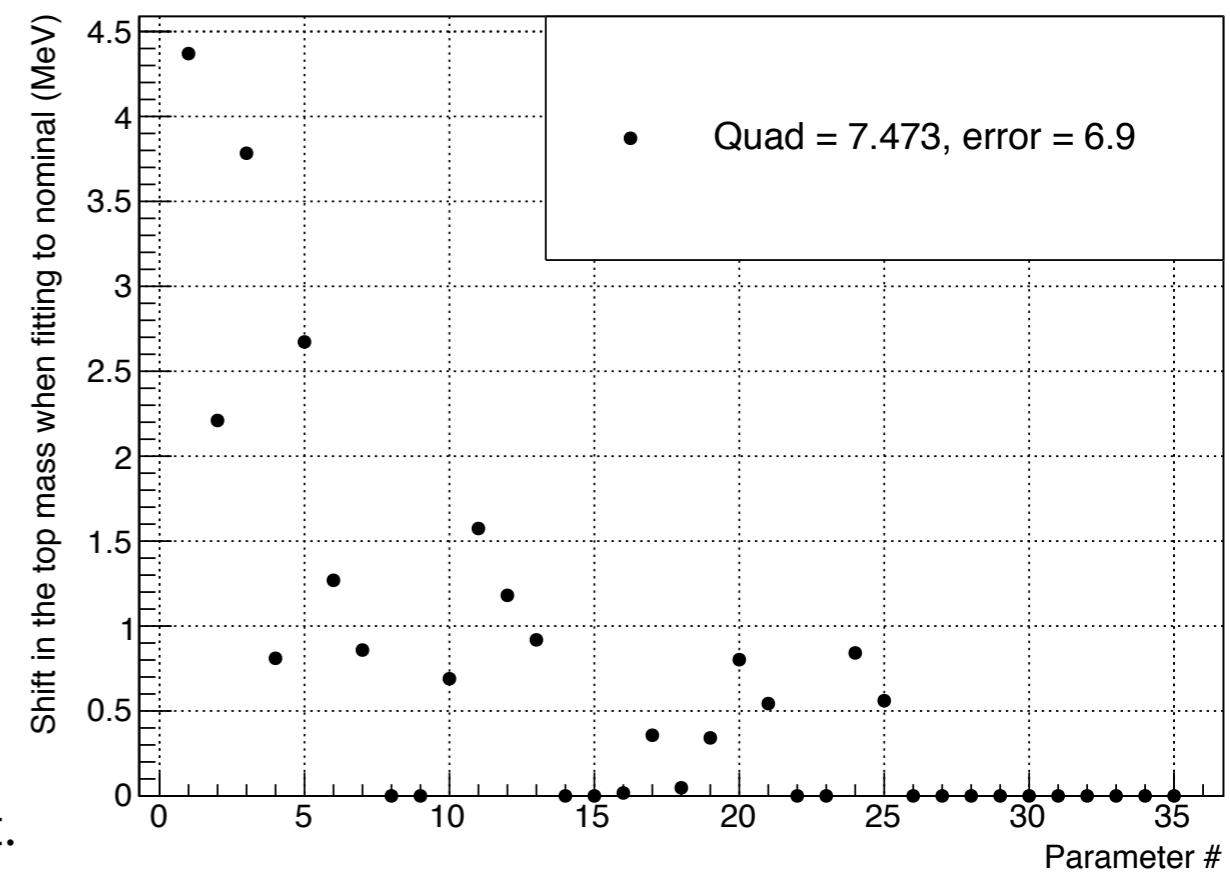

PABLO GOMIS

15

- ▶ To estimate the effect of the luminosity spectrum uncertainty in our study we propagate the error from its 19 free parameters ()
- ▶ Using the 19 parameter errors from the luminosity spectrum reconstruction we generate 38 (19 parameters x 2 σ up, σ down) spectrums.
- ▶ We weight the spectrums with the observable and we fit it to the model weighted with the “nominal” reconstruction.
 - ▶ The propagated error for each parameter is taken as the symmetrisation (σ up, σ down) of the mass shifts obtained through the fits.
 - ▶ The total uncertainty is found by performing $E = \sqrt{E_p \text{ Cov } E_p^T}$.
 - ▶ We find a total uncertainty of **7 MeV**.
 - ▶ ~30M events were used in data and MC for this fit.

- ▶ CLIC @ 380GeV can measure the top quark mass with an uncertainty :
 - ▶ Theoretical uncertainty : between **50MeV to 100MeV** @380GeV. Goal is **50MeV** by improving the fit procedure.
 - ▶ Statistical uncertainty : $\sim 100\text{MeV}@\text{500fb}^{-1} \rightarrow \sim \text{70MeV}@1\text{ab}^{-1}$ (including the effect of the luminosity spectrum)
 - ▶ Propagation of the uncertainty on the luminosity spectrum determination on the top mass: **$\sim 10\text{MeV}$**

END

SENSITIVITY TO THE TOP QUARK MASS

- ▶ In order to evaluate the sensitivity of the observable to the top mass we generate pseudo data of certain luminosities.
- ▶ We assume that the real number of events in that bin will follow a Poisson distribution with a mean equal to the multiplication of the cross section expected for each of the bins by the integrated luminosity.
- ▶ By generating thousands of datasets and fitting them to the theoretical model we obtain thousands of values for the mass, which then are used to fill a histogram.
- ▶ Then we fit the histogram to a gaussian and we estimate the precision for the mass measurement as its sigma.

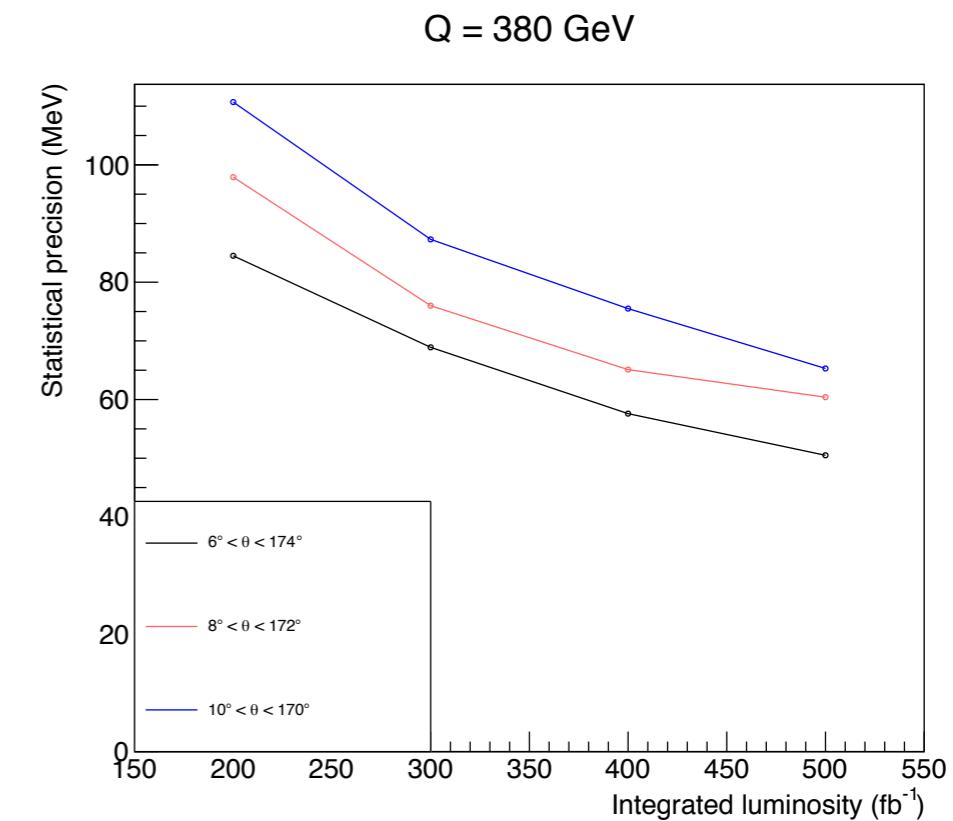

SENSITIVITY TO THE TOP QUARK MASS (II)

33

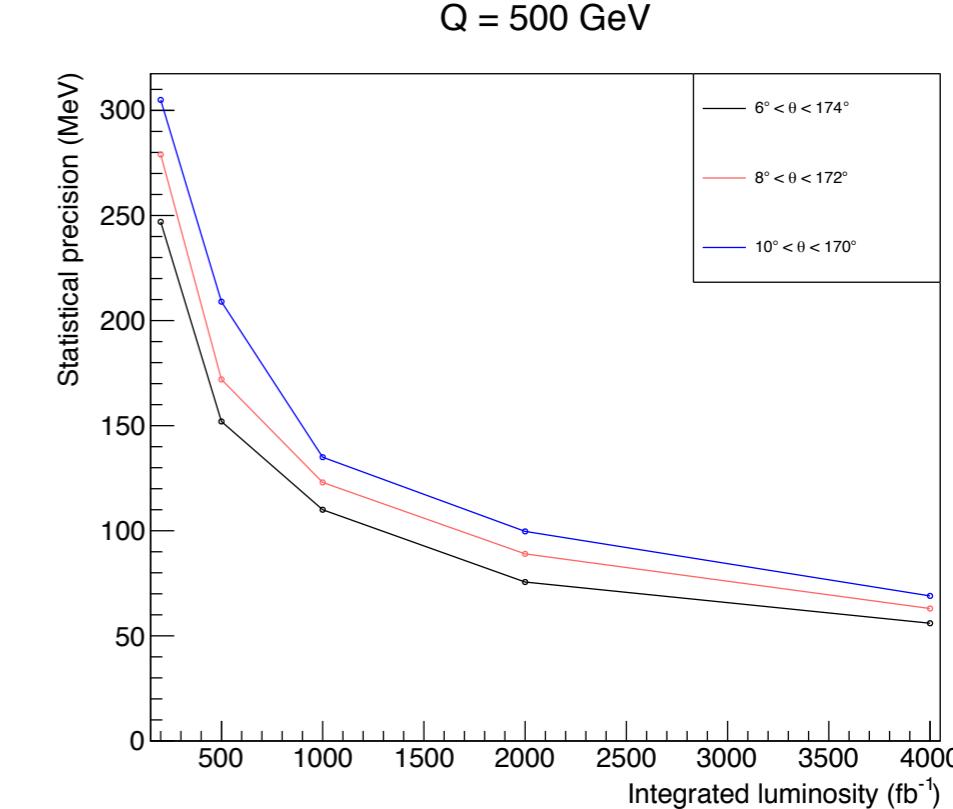

Considering a detector coverage of $6^\circ < \theta < 174^\circ$

	200 fb $^{-1}$	500 fb $^{-1}$	1000 fb $^{-1}$	4000 fb $^{-1}$
σ_m (MeV) @380 GeV	85	50

LUMINOSITY SPECTRUM WEIGHTING

34

- In the experiment, s isn't fixed to 380 GeV, but instead, it has a spectrum. To account for that, we fold our model with the luminosity spectrum.

- We weight our observable distributions of a given Q with the luminosity spectrum.
