Femtoscopic studies on proton- Ξ^- and proton- Ω^- correlations in p-Pb and pp collisions with ALICE

Tuesday 11 June 2019 18:45 (2 hours)

Two-particle correlations can be used to probe the strong interaction between nucleons and multi-strange baryons. We will show measurements of correlation functions of proton- Ξ^- pairs in p-Pb collisions at $\sqrt{s_{\rm NN}}$ = 5.02 TeV, and proton- Ω^- pairs produced in high-multiplicity pp collisions at $\sqrt{s} = 13$ TeV. Utilising newly developed femtoscopic techniques, we will demonstrate how these measurements can be compared to Lattice QCD and phenomenological model predictions for the strong potentials between protons and multi-strange baryons. Using the measured proton-proton correlation function to constrain the size and shape of the baryonemitting source, and the excellent precision of the ALICE data, we will demonstrate that our measurements are highly discriminating with respect to these predictions. The measured proton- Ξ^- correlation function indicates the corresponding strong interaction is attractive, while the proton- Ω^- correlation function will be compared to models predicting a bound nucleon- Ω^- di-baryon state. A precise evaluation of these models of the nucleon-hyperon interaction is crucial for the modelling of the core of neutron stars. We will discuss the consequences of our measurements for the equation of state of neutron-rich matter including hyperons.
