

# STOPPING PROTONS ANALYSIS

---

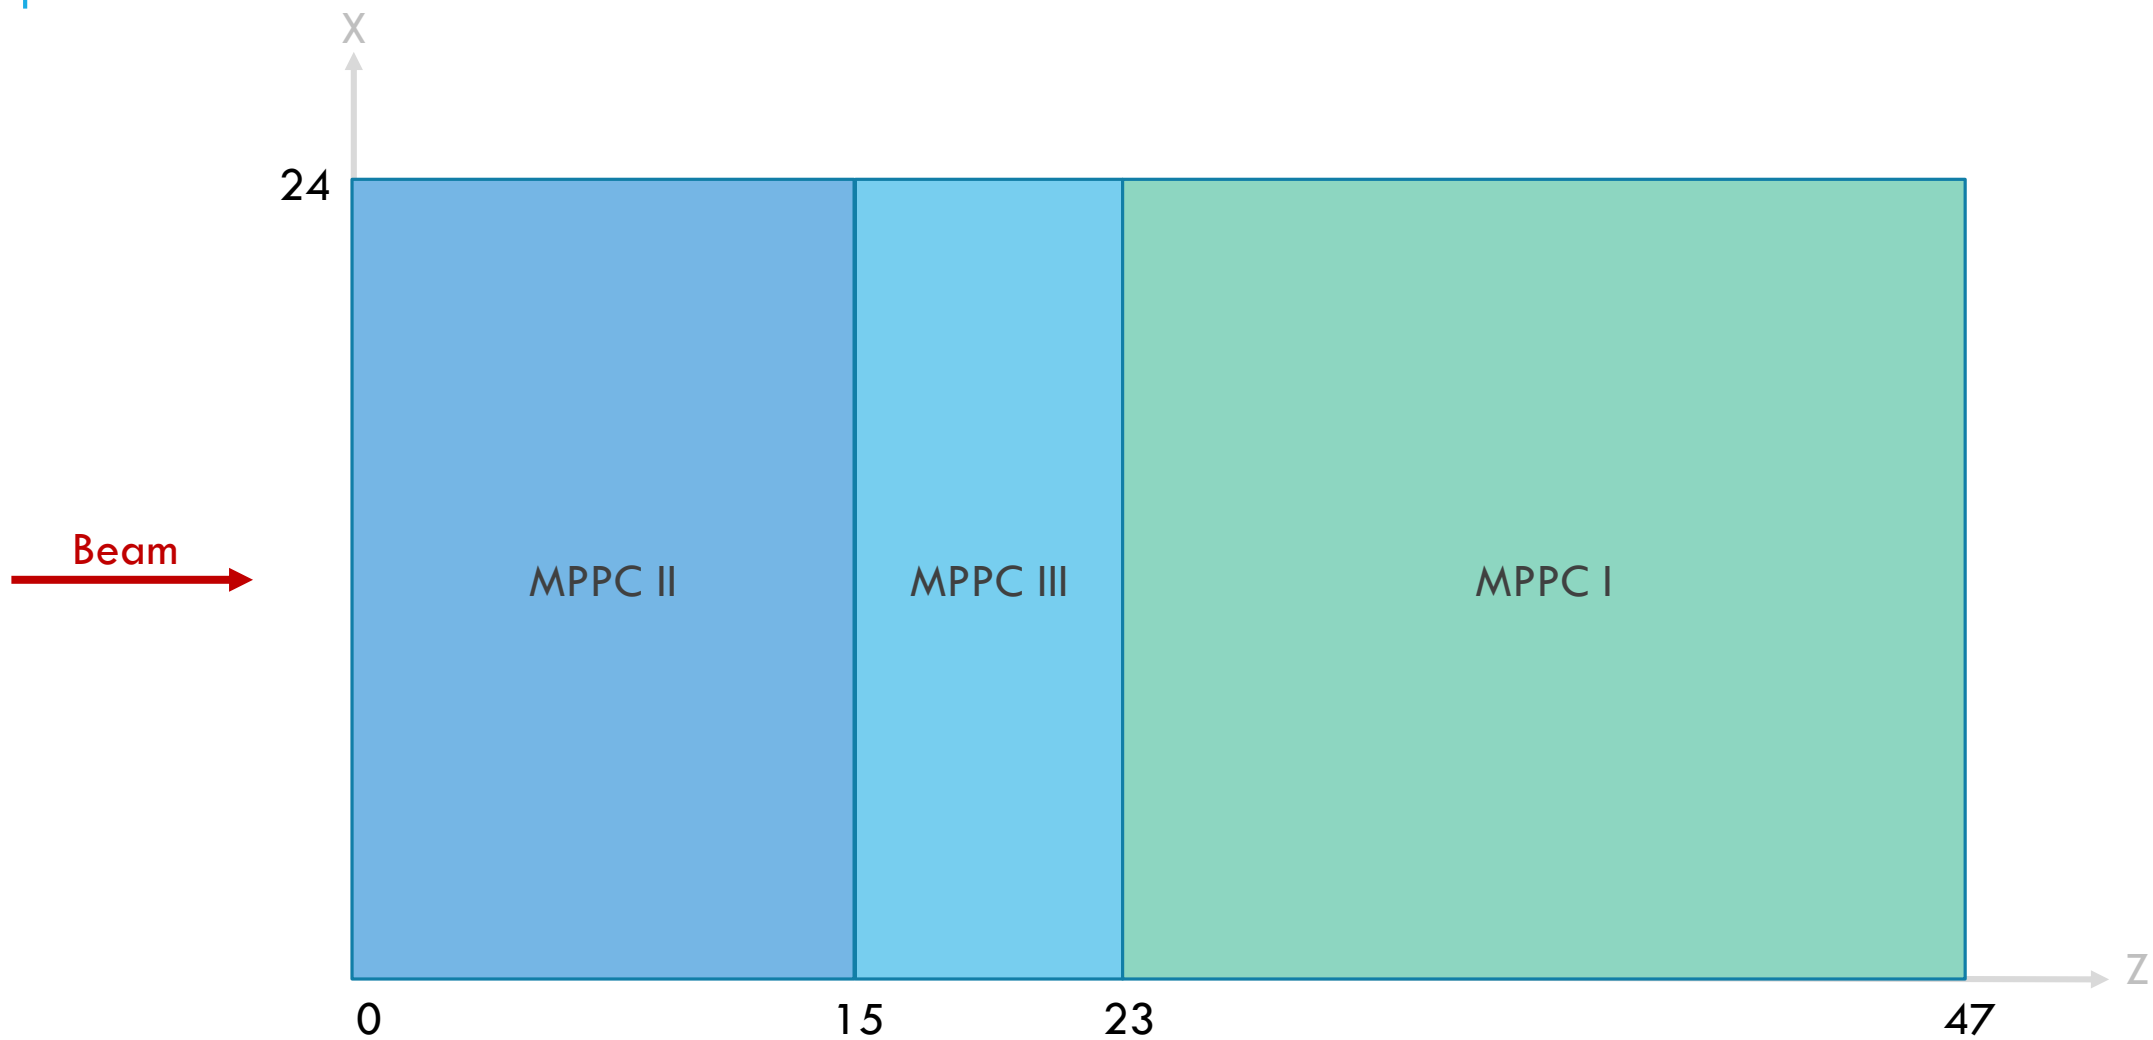

# GOAL

To study stopping protons in the SuperFGD using data from the Aug/Sep test beam, analyzing where protons stop in the detector.

By considering the three types of MPPCs separately, build a distribution of the energy deposited in the last cell the proton reaches.

Use the shape of the distribution to check whether there is a saturation effect.

# MPPCS IN THE DETECTOR

# STEPS

1.  $dE/dx$
2. Event Selection.
3. Treat MPPCs separately.
4. Obtain relative  $dE/dx$  from end point of each event.
5. Build histogram for energy deposited in the last cell.

# DATA SAMPLE

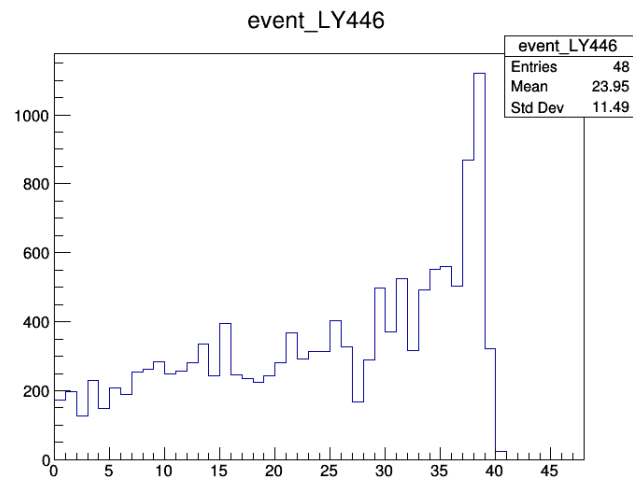

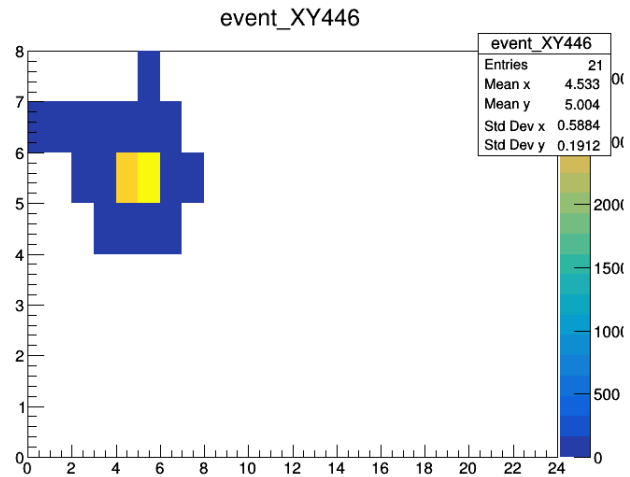

0.8 GeV/c Protons.

Magnet ON, 135 A.

Default HG, default LG (55, 55).

Proton trigger ON.

# 1. ENERGY DEPOSITION

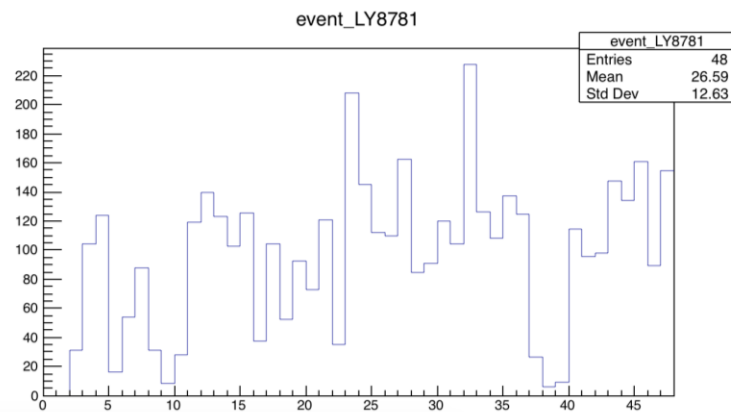

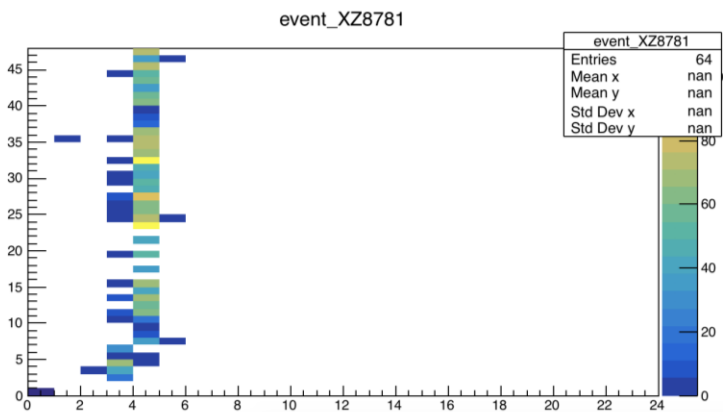

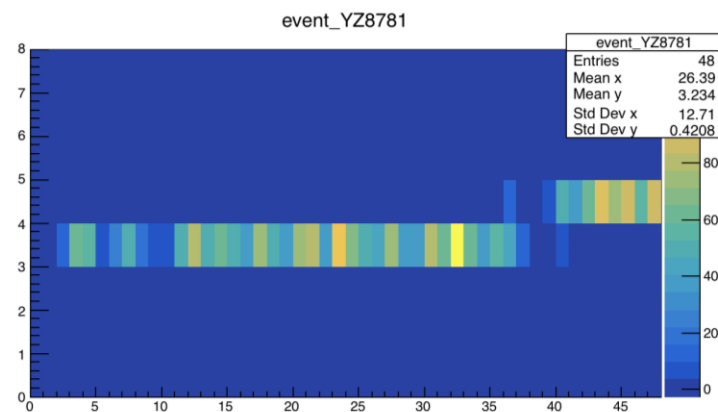

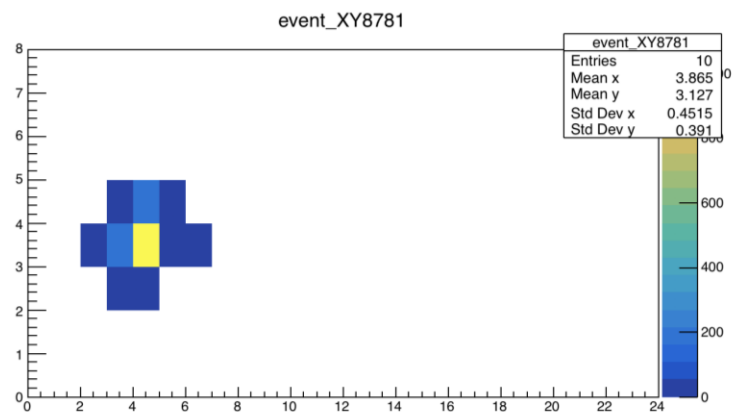

Code by Sasha

## 2. EVENT SELECTION

Need to consider different event scenarios.

Which to include, which to discard.

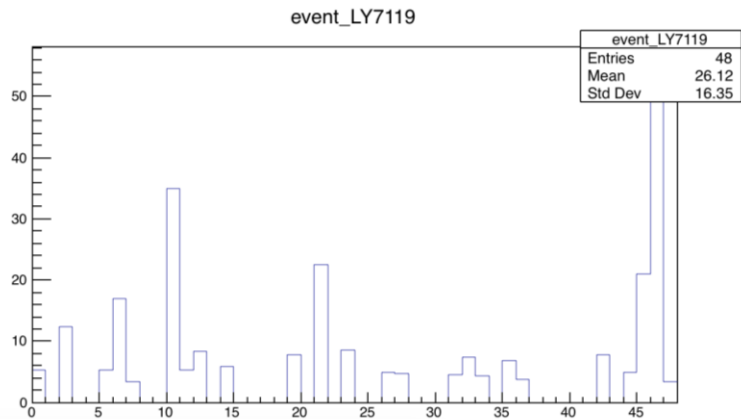

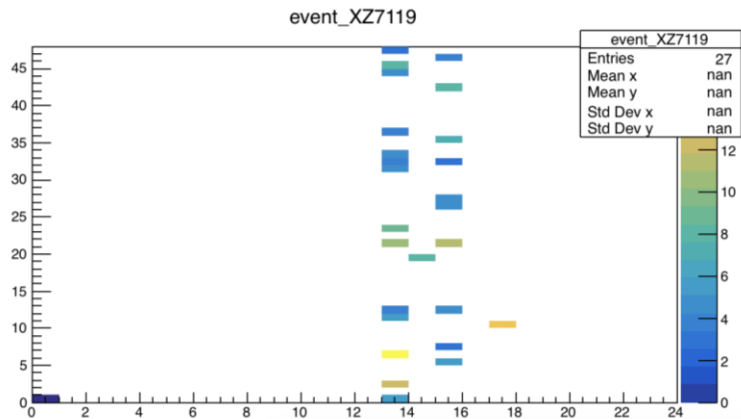

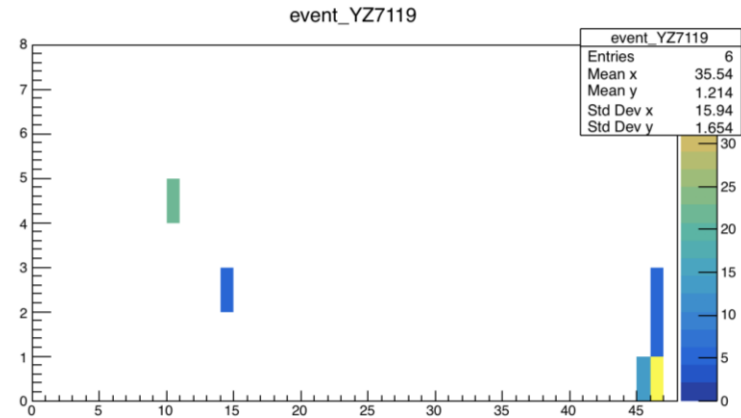

# NO STOP

Cut: No energy deposited in last layer (Z=47)

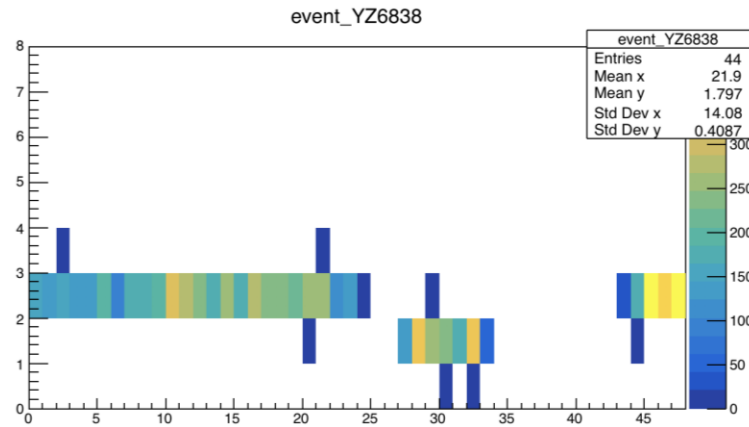

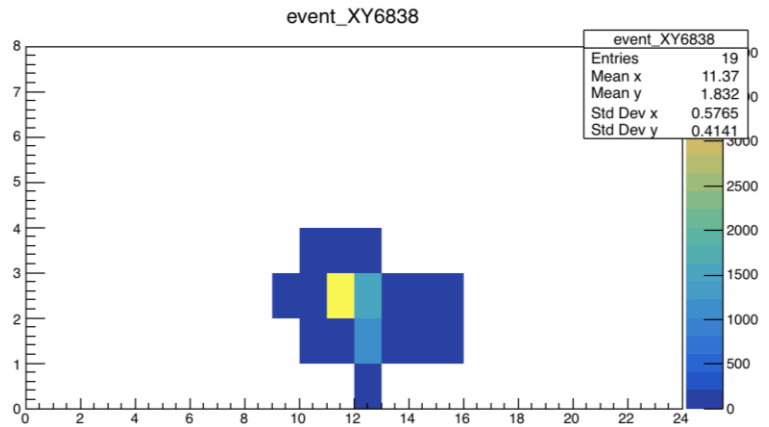

# MEANINGLESS EVENTS

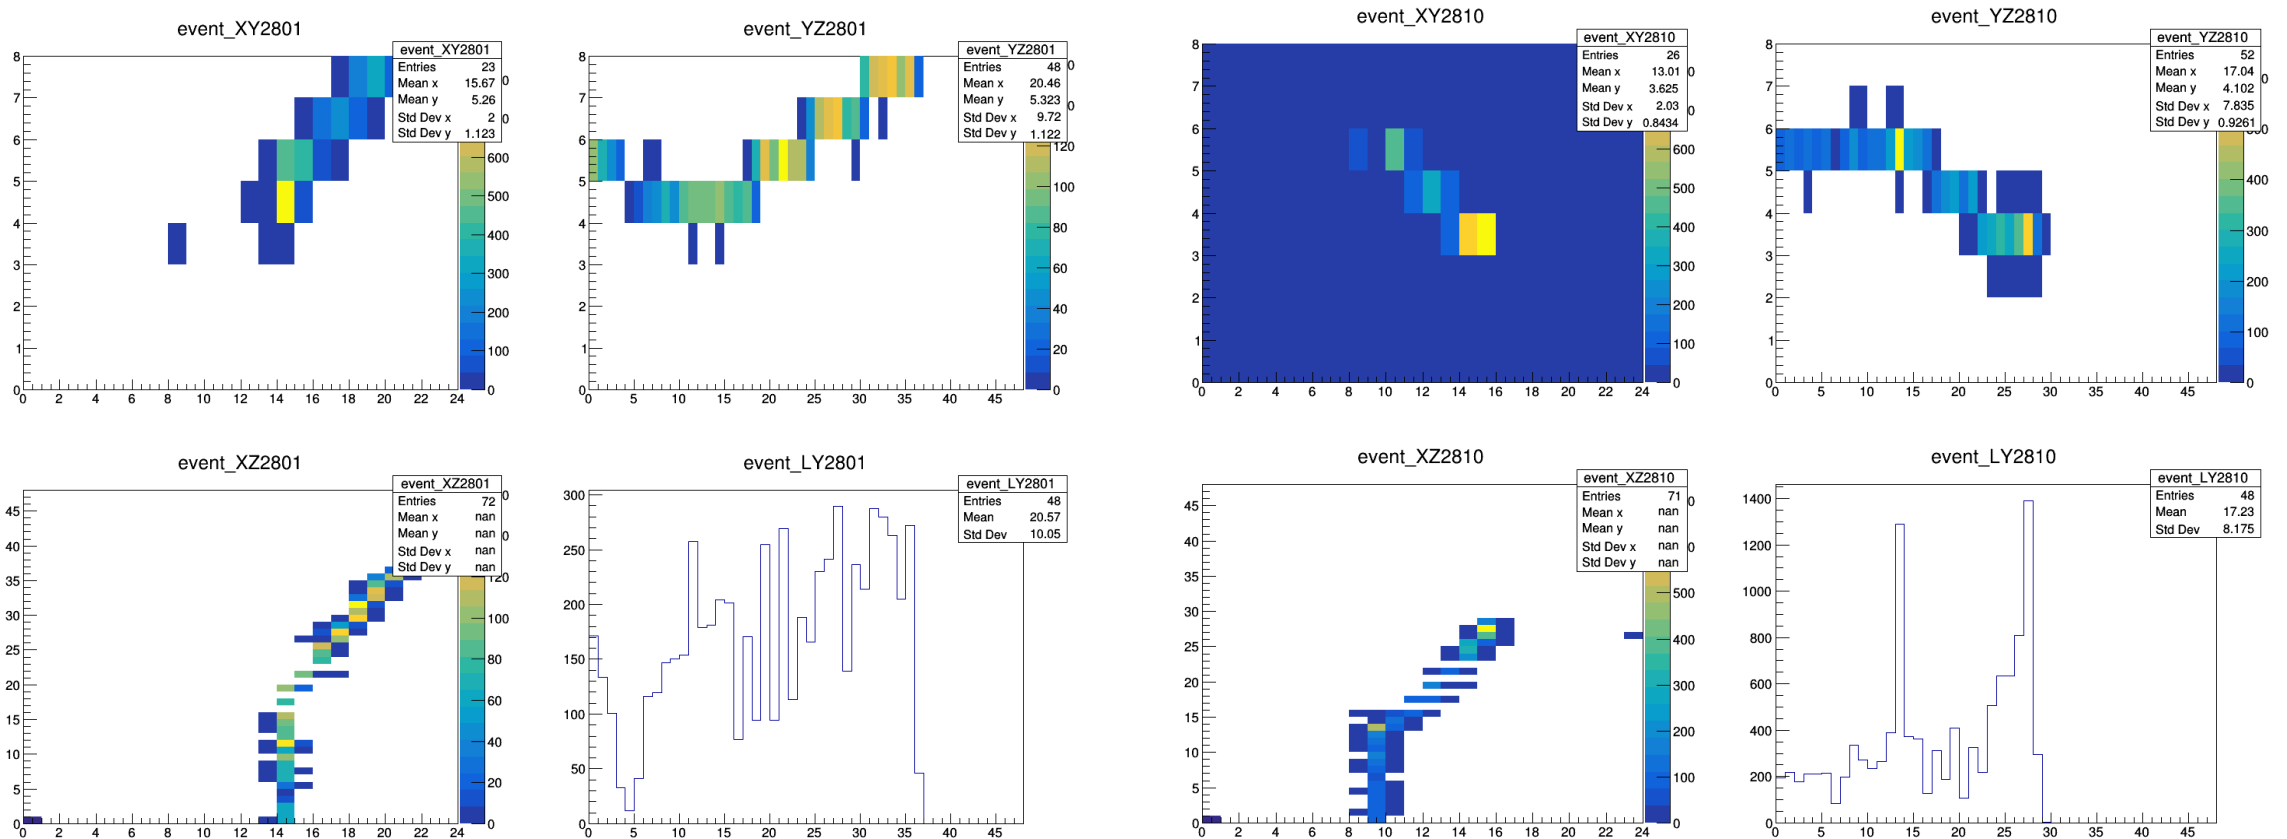

Cut: Energy deposited at the peak  $> 250$  p.e.

# DISCONTINUITIES

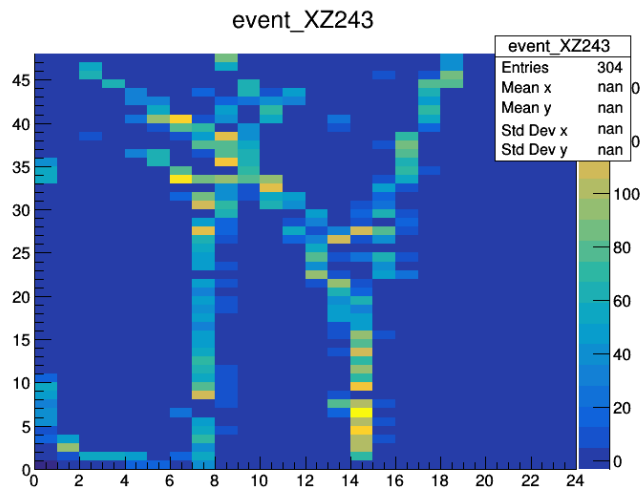

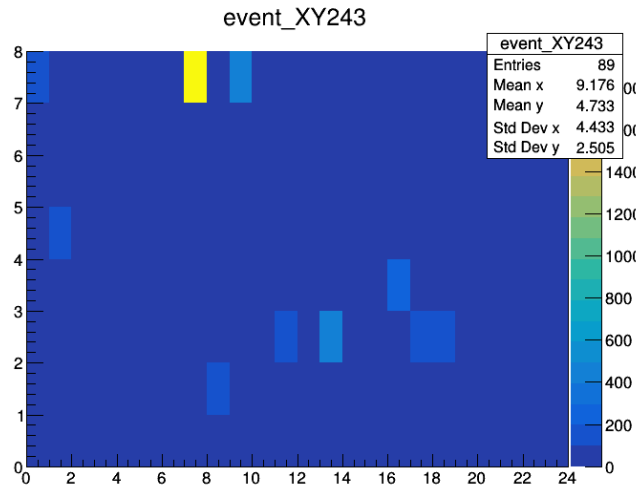

Cut: Before the peak, max number of allowed layers with ZERO deposited energy is 2.

# SCATTERINGS, SOMETIMES LEAVING THE DETECTOR?

Cut: For the front (XY) view, stdDevX and stdDevY both  $< 1.0$

# MULTIPLE TRACKS

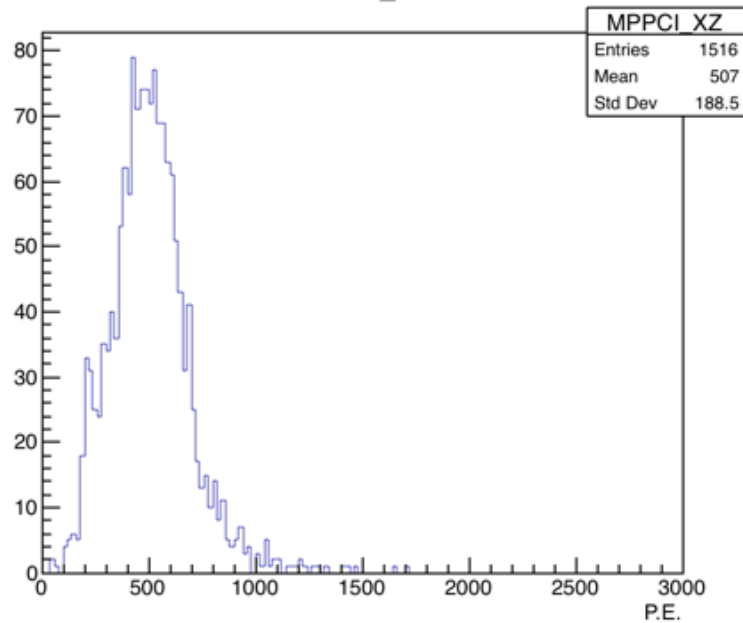

Eliminated by previous cut.

# FIRST ROUND OF APPLIED CUTS

- Energy deposited at the peak  $> 250$  p.e.
- No energy deposited in last layer ( $Z=47$ )
- Before the peak, max number of allowed layers with ZERO deposited energy is 2.
- For the front (XY) view,  $\text{stdDevX}$  and  $\text{stdDevY}$  both  $< 1.0$

From 4525 Events  $\rightarrow$  1908 Events (42% left)

# NEXT

- Take a sample with 0.5 GeV/c protons to get more events stopping in the first half of the detector.
  - more statistics for MPPCII and MPPCIII
- Do the ADC → p.e conversion outside the Stopping Proton code then test the code with the new branches.
