Electric Aircraft Thermal Challenge

Current proposed solutions include:
- Ram air HX
  - adds weight and aircraft drag
- Convective skin cooling HX
  - adds weight, drag, and inefficient
- Dumping heat into fuel
  - limited thermal capacity
- Dumping heat into lubricating oil
  - limited thermal capacity
- Active cooling
  - adds weight and consumes engine power
- Phase change cooling
  - adds weight and limited thermal capacity
- Heat pipe, pumped multiphase, vapor compression
  - adds weight and consumes engine power

50kW to >800kW of low grade thermal heat trapped within composite aircraft body
Thermal Limits

Dumping heat into:
- Fuel (limited 50 kW),
- outer mold line (limited 300 kW),
- ram air (see below for losses),
- by-pass air (see below for losses),

Thermal Runaway with Composite Fuselage

Electric Aircraft Propulsion Thermal management technology impacts performance and safety certification
Prefer technology that:
- improves fuel efficiency,
- reduces emissions,
- removes heat from:
  - small core engines, more electric composite aircraft, and high power electric propulsion systems
- reduces vehicle mass
- reduces thermal signature for military
IDEA: Aero-Vascular Energy Management with Acoustic and Vapor Energy Transport

Three Key Points:
1. Recycle waste energy with heat pumping powered with core waste energy
2. Additive manufactured airframe enables sophisticated heat transport
3. Solid-state thermal control allows transporting energy with no moving parts
Heat Energy Extraction

• Key Point: Most thrust (>80%) produced in by-pass air of commercial aircraft
  • Turbofans have bypass ratio from 6 to 12
  • Turboprop have bypass ratio from 50 to 100
  • Hybrid electric distributed propulsion up to 100
  • Small core further increases by-pass ratio

• Idea: Extract waste energy from core
  • Minimal impact on overall thrust
  • Reduce jet noise that scales as $V^8$
  • ~30 MW waste heat available on B737
    Extract only 10%, 3 MW -> 1MW acoustic energy available
Energy Transport With Acoustic Waves

Basic principle is to use aircraft engine waste heat to produce a high intensity acoustic wave with no hot moving parts that can be used for power generation or component cooling. The temperature gradient between hot and cold HX efficiently creates the acoustic waves.

All energy is delivered through small hollow acoustic tubes.
No Moving Part Acoustic Heat Pump

Acoustic Mechanical Work Energy Moves Heat From Cold to Hot
Acoustic Heat Pump Efficiency

All aircraft waste heat is now useful high temperature heat

Free Superconducting

Free Acoustic Mechanical Work Input From Nozzle

Electric Actuators, Cabin, Cables, Power Electronics, Protection, Machines

Makes electric parts and powertrain effectively 100% efficient
Solid-State Energy Transfer Control

**Acoustic Energy Control Method**
- Small Input
- 300K
- Heat Transport On
- 800K
- Acoustic Wave On
- 900K
- Acoustic Wave Off
- No Heat
- 330K
- No Input

**Vapor Energy Control Method**
- Heat Transport On
- No Heat
- Evaporator
- Active Condenser
- Inactive Condenser
- Gas Reservoir
- Noncondensable Gas
- Working Fluid
- Low Heat
Waste Heat Re-Use Options

Solid-state (no moving part) energy recycle and distribution

- localized skin heating
  - for active lift/drag management,
- de-icing/anti-icing,
- powertrain cooling,
- cabin thermal management,
- engine recuperation,
- thrust enhancement with by-pass air
- military cloaking with thermal skin temperature shifting or nozzle rejection

Simple solid-state heat distribution and recycling
Remove waste heat from turbine exhaust with OGV fins located parallel to exhaust flow for flow straightening and high heat transfer rate.

Use multiple independent flight-weight no moving part thermo-acoustic power tubes to generate acoustic waves from waste jet exhaust heat.
Structural Pressurized Acoustic Tubes

Light-weight gaseous pressurized helium filled tube delivers energy from turbine to anywhere on aircraft and provides flight-weight structural support.

Acoustic heat pumps can provide cooling using the delivered acoustic energy.
Net System Cycle Benefit Range (1.6% - 16%)

Example idealized net benefit calculation (16% fuel savings):
- 24MW thrust for Boeing 737 using a pair of CFM56 engines operating at 50% efficiency produce ~12MW of waste heat at 450°C out the nozzle with 25°C by-pass fan air surrounding it
  - 52% of Carnot Efficiency for WHR, approximately 4MW of mechanical acoustic energy available
- 1MW of low-grade 100°C distributed heat sources throughout the insulated composite aircraft requires ~3MW of mechanical input to raise to 600°C
  - 44% of Carnot Efficiency for heat pump, heat pipes return the 600°C 4MW of energy to combustor

Best case idealized scenario achieves fuel savings of 16% while providing a flight-weight method for managing the aircraft’s heat sources without adding aircraft drag and weight. All heat is used in the most optimal way and ultimately rejected out the nozzle instead of through the aircraft body.

Drop-in Solution with Conservative Assumptions (1.6% fuel savings):
Note that the outlet guide vanes as currently installed in the CFM56 could act as WHR fins extracting about 10% of the nozzle waste heat so that 100kW of low-grade distributed 100°C aircraft heat sources could be returned to the combustor as 400kW, 600°C useful heat resulting in a potential fuel savings of 1.6%.

This changes aircraft thermal management from being a burden on aircraft performance to an asset.
TREES changes aircraft thermal management from being a necessary burden on aircraft performance to a desirable asset. It improves the engine performance by recycling waste heat and ultimately rejecting all collected aircraft heat out through the engine nozzle.

**Key Features Include:**

- Turbofan and/or fuel cell waste heat is used to generate ducted acoustic waves that then drive distributed acoustic heat pumps and/or generate power throughout the aircraft.
- Low grade powertrain waste heat is converted into high grade recycled heat and returned to the engine combustor via heat pipes or additional acoustic tubes.
- Pressurized acoustic and heat pipe tubes can be directly integrated into the airframe to provide structure support with mass reduction.
- Fuel savings of 16% are estimated with a purpose-built system.
- All aircraft heat is rejected through engine nozzle, by-pass stream, outer mold line de-ice.
- Non-provisional Patent Filed With Priority Date November 6, 2015.
Appendix: Basic Theory
Example Wave Generation, Acoustic Tube, and Heat Pump as One Unit

Note the power generation, distribution, and heat pump tube can be any length and curved to fit within aircraft. Electric power or cooling can be delivered anywhere in the aircraft without power conductors.
Thermodynamic Cycle

Gas displacement boundary

compression

displacement, $P \uparrow$

expansion

Displacement, $P \downarrow$

$W_{cmp} < W_{exp}$
Two stage cascade

\[ \frac{W_{cmp}}{W_{exp}} \propto \left( \frac{T_{cold}}{T_{hot}} \right)^2 \]
PV Phasing

- $P_1$ phasors everywhere nearly constant
- $U_1$ phasors progressively lag due to volume (compliance)
- Ideally, $P_1$ and $U_1$ in phase in regenerators
- Gas inertia (inertance) can be used to counter $U_1$ lag
- E.g. Swift inter-stage inertance tube (see reference 4)
End Transducer Options

High Impedance
(Piezo or magnetorestrictive)

Low Impedance
(Moving Magnet actuator)

Impedance is \( \frac{P_1}{U_1} \)
High Impedance Matching

- Quarter-wave solid resonator converts low stirling impedance to high transducer impedance
- Low Dissipation losses critical
- Coef of restitution > 0.9999
- Three-dimensional effects?
- Piezo transducers prefer higher frequency than stirling thermodynamics allows

\[
\begin{align*}
\text{Impedance matcher} & \quad \text{Impedance matcher} \\
\begin{cases}
\mathbf{P}_1 \\
\mathbf{u}_1
\end{cases}
\end{align*}
\]
Electro-acoustic transducer (size & weight versus capacity)?

• Not required since can use standing wave driver (see Swift ref. 1)

Key Point is the type and size of driver can be very small because of thermo-acoustic amplification from multiple stages in series. Next series of slides explains this.

And note that TREES uses a traveling wave without the loop shown in F1. b) by using an RC Helmholtz terminator.
