# **MYSTERY OF BARYON CORRELATIONS**

**Małgorzata Janik**

9/09/2019

$0.4 < p_{T\text{-sum}} < 0.8 \text{ GeV}/c$

**Back-to-back jets**

**Resonances**

**Same jet**

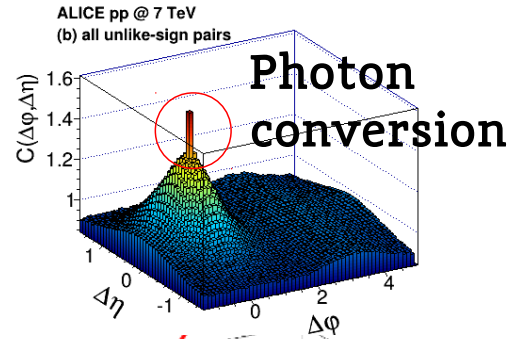

**Momentum conservation**

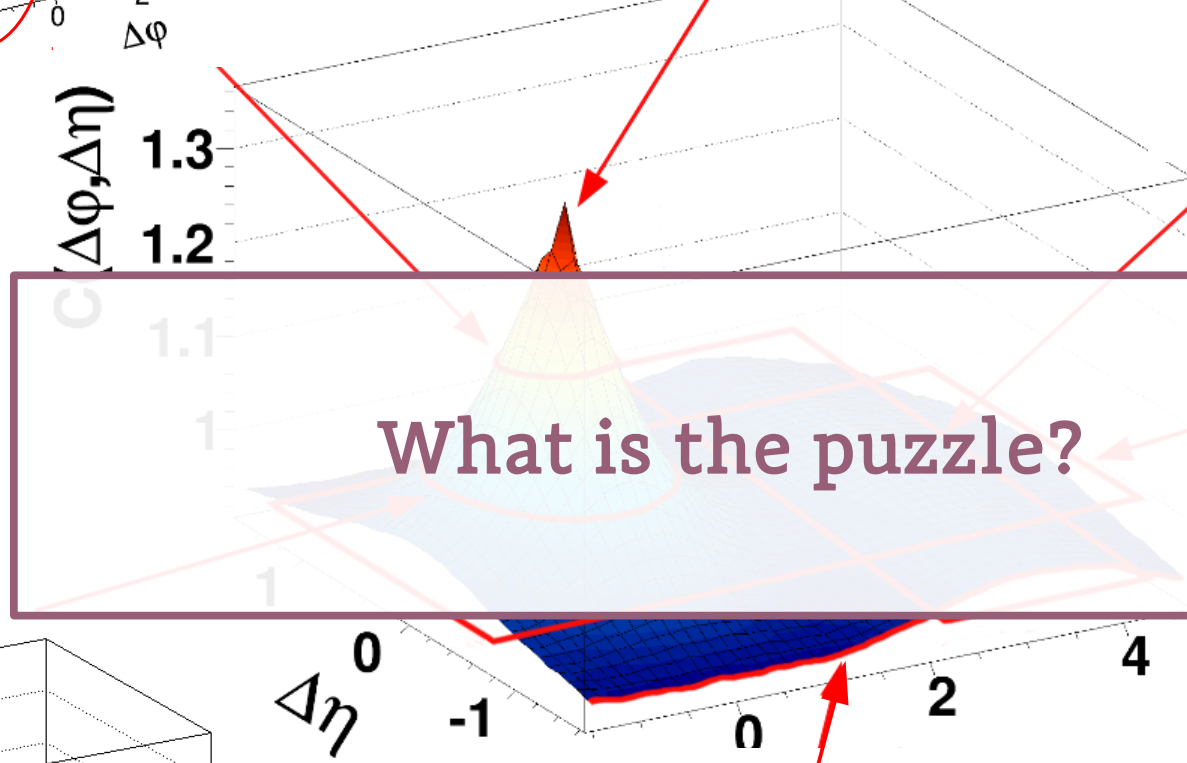

$$\Delta\eta = \eta_1 - \eta_2$$
$$\Delta\phi = \phi_1 - \phi_2$$

$0.4 < p_T\text{-sum} < 0.8 \text{ GeV}/c$

**Back-to-back jets**

**Resonances**

**Same jet**

**Momentum conservation**

$$\Delta\eta = \eta_1 - \eta_2$$
$$\Delta\phi = \phi_1 - \phi_2$$

# Data sample & analysis

- Let's take “vanilla events” = no QGP, no high multiplicities
  - And see how different particles are distributed in momentum space
- First seen in ~200 million **minimum bias pp** collisions at 7 TeV collected by ALICE in 2010
  - But also other energies, systems, kinematic regimes....
- Kinematic cuts:
  - $0.2 < p_T < 2.5$  (4.0) GeV/c for pions
  - $0.3 < p_T < 2.5$  (4.0) GeV/c for kaons
  - $0.5 < p_T < 2.5$  (4.0) GeV/c for protons
  - $0.7 < p_T < 2.5$  (4.0) GeV/c for lambdas
  - $|\eta| < 0.8$

98-99% purity

# $\Delta\eta\Delta\phi$ of identified particles

Eur.Phys.J. C77 (2017) 8, 569

Like-sign

# What does it mean?

## Strong near side peak:

- probability of producing two particles close in phase space is higher than in other directions

## Possible reasons:

- (mini)jet collimation
- resonances
- quantum statistics
- FSI (strong, Coulomb)
- conservation laws (charge, strangeness, baryon number)

# What does it mean?

## Strong near side peak:

- probability of producing two particles close in phase space is higher than in other directions

## Possible reasons:

- (mini)jet collimation
- resonances
- quantum statistics
- FSI (strong, Coulomb)
- conservation laws (charge, strangeness, baryon number)

# What does it mean?

## Strong near side peak:

- probability of producing two particles close in phase space is higher than in other directions

## Possible reasons:

Eur.Phys.J. C77 (2017) 8, 569

Like-sign

(e)  $\pi^+\pi^+ + \pi^-\pi^-$

(f)  $K^+K^+ + K^-K^-$

*This one looks different!*

(g)  $pp + \bar{p}\bar{p}$

# What does it mean?

## Strong near side peak:

- probability of producing two particles close in phase space is higher than in other directions

## Possible reasons:

- (mini)jet collimation
- resonances
- quantum statistics
- FSI (strong, Coulomb)
- conservation laws (charge, strangeness, baryon number)

# What does it mean?

## Anti-correlation in (0,0):

- probability of producing two particles close in phase space is **lower** than in other directions

## Possible reasons:

- (mini)jet collimation
- resonances
- quantum statistics
- FSI (strong, Coulomb)
- conservation laws (charge, strangeness, baryon number)

# $\Lambda$ and $p\Lambda$ correlation functions

Eur.Phys.J. C77 (2017) 8, 569

- Useful to check if effect persists for other baryons than protons – is this a common effect for all baryons?

- Correlation functions were calculated for  $\Lambda\Lambda$  and  $p\Lambda$  pairs

- $\Lambda$  baryons are neutral  $\rightarrow$  no Coulomb repulsion

- $p$  and  $\Lambda$  are not identical  $\rightarrow$  no effect from Fermi-Dirac statistics

- All observations from  $pp$  can be extended to  $\Lambda\Lambda$  and  $p\Lambda$

# Do we understand anti-correlation?

## Anti-correlation in (0,0):

- probability of producing two particles close in phase space is **lower** than in other directions

## Possible reasons (pΛ):

- (mini)jet collimation
- resonances
- quantum statistics
- **FSI (strong, Coulomb)**
- **conservation laws** (charge, strangeness, **baryon number**)

## The same, just projection

# Do we understand anti-correlation?

## Anti-correlation in (0,0):

- probability of producing two particles close in phase space is **lower** than in other directions

## Possible reasons:

- **(mini)jet collimation**
- resonances
- quantum statistics
- **FSI (strong, Coulomb)**
- **conservation laws (charge, strangeness, baryon number)**

## The same, just projection

Can this be just a manifestation of baryon number conservation?

Producing many (at least 4, to get pp correlation function) **baryons** (heavy particles) in similar direction may be just too improbable due to energy constraints...

# MC models do not reproduce

Eur.Phys.J. C77 (2017) 8, 569

Like-sign

# Do we understand anti-correlation?

## Anti-correlation in (0,0):

- probability of producing two particles close in phase space is **lower** than in other directions

## Possible reasons:

- (mini)jet collimation
- resonances
- quantum statistics
- FSI (strong, Coulomb)
- conservation laws (charge, strangeness, baryon number)

+ momentum conservation  
(but this is there for all possible pairs)

(g)  $pp + \bar{p}\bar{p}$

# Do we understand anti-correlation?

## Anti-correlation in (0,0):

- probability of producing two particles close in phase space is **lower** than in other directions

## Possible reasons:

- **(mini)jet collimation**
- resonances
- quantum statistics
- **FSI (strong, Coulomb)**
- conservation laws (charge, strangeness, baryon number) + momentum cons.
- **ANY OTHER REASONS? → no ideas so far**

(g)  $pp + \bar{p}\bar{p}$

Preliminary

# Rapidity correlations in $e^+e^-$

A Parametrization of the Properties of Quark Jets  
 R.D. Field, R.P. Feynman (Caltech)

Nucl.Phys. B136 (1978) 131

From mechanism of jet production:

Two primary hadrons with the same

**baryon number**

(or **charge** or **strangeness**)

are separated by at least two steps in rank ("rapidity").

R. Feynman  
 "Quark Jets"  
 8th ISMD 1977

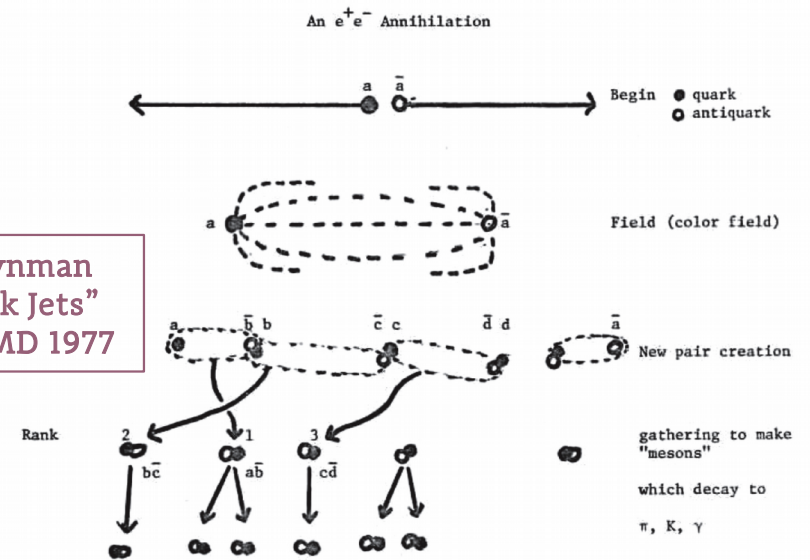

Fig. 10. Transparency from a talk Feynman gave on our model for how quarks fragment into hadrons at the International Symposium on Multiparticle Dynamics (ISMD), Kaysersberg, France, June 12, 1977.

We are not likely to find two baryons or two antibaryons at the same rapidity

Models for  $e^+e^-$  agree with observations seen in data

TPC/Two Gamma Collaboration, Phys.Rev.Lett. 57 (1986) 3140

(g)  $pp + \bar{p}\bar{p}$  pairs

The **real problem is baryon production**. [...] so it is clear we still lack some fundamental insight on baryon production, at least in the string context.

Nucl.Phys. A982 (2019) 43-49

# Outlook

- **Wealth of results will be released soon by ALICE**
- **Other small systems: results from pp at 13 TeV and p-Pb collisions**
  - The same structures visible, no significant changes in respect to 7 TeV
- **Heavy-ion collisions**
  - Anti-correlation visible, sitting on top of the significant flow modulation
- **Measure Xi and Omega baryons**
  - Both p-Xi (sharing only one quark) and p-Omega (not sharing any quarks between particles in the pair) show significant anti-correlation
- **Measure high  $p_T$  baryons**
  - The anti-correlation effect does not disappear if we study higher  $p_T$  particles (above 2.5 GeV/c).

# Summary

- We do not understand mechanism of production of one of the most common particles in the Universe: protons
- Effect observed in minimum bias pp 7 TeV “vanilla” events
  - but persists for other systems, multiplicities, momentum ranges
- Common for all baryons
- We need new baryon production framework!
  - Can influence other analyses measuring baryons as well?
- More data available soon!

proton like-sign pairs

PYTHIA 6.4 Perugia-0, pp  $\sqrt{s} = 7$  TeV  
proton like-sign pairs

PYTHIA 8.210 Monash, pp  $\sqrt{s} = 7$  TeV  
proton like-sign pairs

*This one looks different!*

PHOJET 1.12, pp  $\sqrt{s} = 7$  TeV  
proton like-sign pairs

(g) pp +  $\bar{p}\bar{p}$

*None of common MC  
models reproduces  
ALICE data!*

# How does it work?

- For particles from from back-to-back jets (blue): *Away-side ridge*
- centered at  $\Delta\phi = \pi$
- $dN/\Delta\eta \sim \text{const}$ , if averaged over many events

# One step further: identified particles!

Unexplored phenomena: **conservation laws** and their influence on **particle production mechanisms** – study via correlation functions for particles with **different quark content**

**Pion:**  
• Charge

**Kaon:**  
• Charge  
• Strange quark

**Proton:**  
• Charge  
• Baryon

particles	momentum	conservation laws		
		charge	strangeness	baryon number
pions	✓	✓		
kaons	✓	✓	✓	
protons	✓	✓		✓

Useful to perform analysis in a more differential way:

- **charge dependence**

for unlike-sign pairs quantum numbers conserved: stronger correlation

for like-sign pairs new particles need to be produced: weaker correlations

- **identified particles**

# $\Delta\eta\Delta\phi$ of protons vs $p_T$

$$p_T^{\text{sum}} = |p_{T1}| + |p_{T2}|$$

$1.0 < p_T^{\text{sum}} < 2.8 \text{ GeV}/c$

ALICE Preliminary, pp  $\sqrt{s} = 7 \text{ TeV}$   
proton unlike-sign pairs

$2.8 < p_T^{\text{sum}} < 8.0 \text{ GeV}/c$

Near-side peak grows with  $p_T$   
(more contribution from jets)

$\overline{pp}$

ALI-PREL-87033

$1.0 < p_T^{\text{sum}} < 2.8 \text{ GeV}/c$

ALICE Preliminary, pp  $\sqrt{s} = 7 \text{ TeV}$   
proton like-sign pairs

$2.8 < p_T^{\text{sum}} < 8.0 \text{ GeV}/c$

Anticorrelation dip

$pp + \overline{pp}$

$p_T$  growth

Small peak disappears for high  $p_T$ -sum

Shape of the dip does not change

Małgorzata Janik, ŁG

ALI-PREL-87049

# Comparison to MC models: like-sign

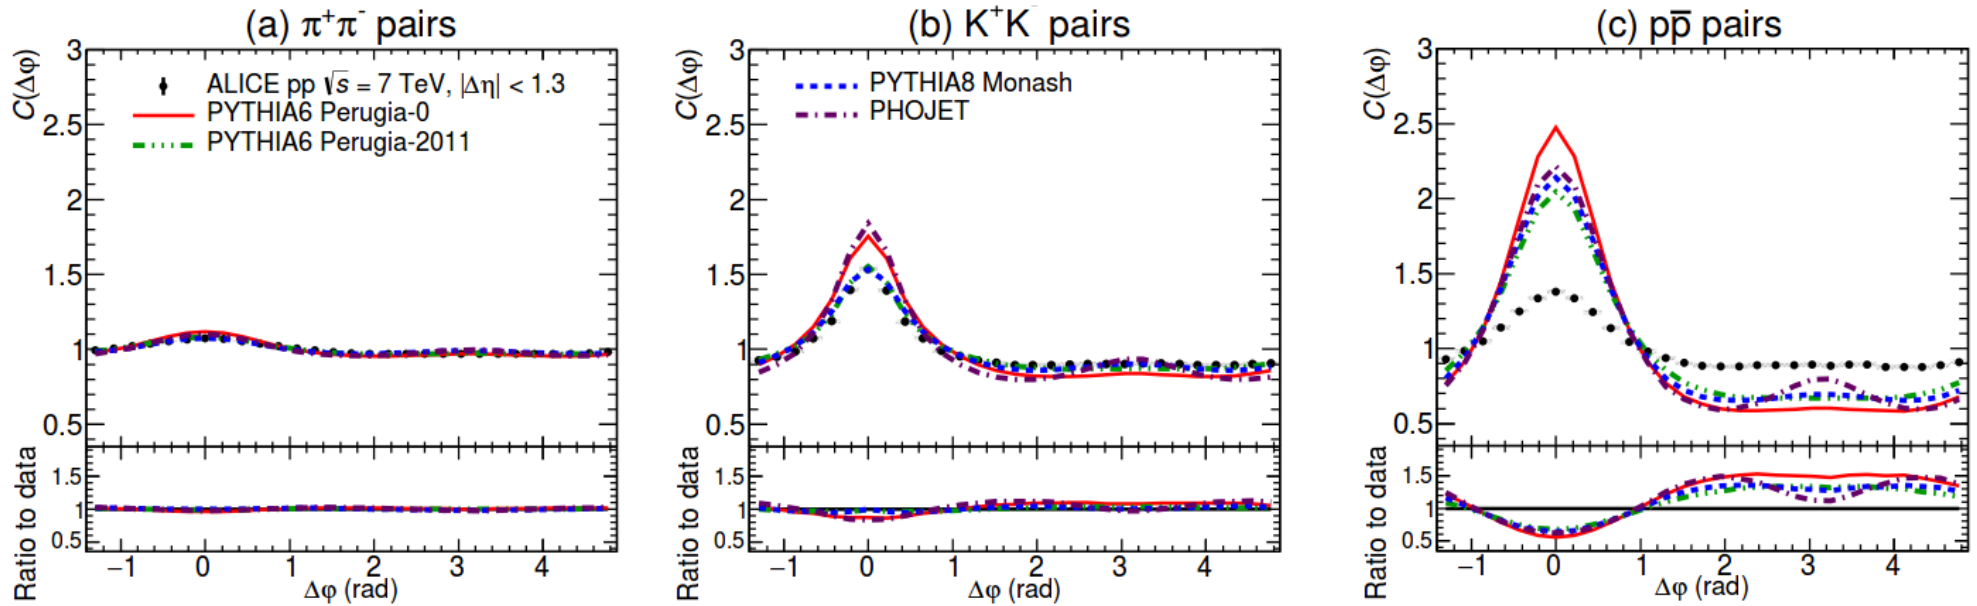

arXiv:1612.08975

- The models reproduce reasonably well the angular correlations for mesons
- The models fail to reproduce the results for baryons – they are able to produce 2 baryons close in the phase space
- **Energy and local baryon-number conservation laws are implemented in all studied models - not enough to explain the anti-correlation observed in experimental data**

# Comparison to MC models: unlike-sign

arXiv:1612.08975

- The models reproduce reasonably well the angular correlations for mesons
- The models fail to reproduce the results for baryons – they are able to produce 2 baryons close in the phase space, also baryon-antibaryon pairs have 2 x the magnitude for MC
- **Energy and local baryon-number conservation laws are implemented in all studied models - not enough to explain the anti-correlation observed in experimental data**

# $\Delta\eta\Delta\phi$ of baryons

Małgorzata Janik, ŁG

Eur.Phys.J. C77 (2017) 8, 569

- Projections show how similar are baryon-baryons pairs to each other
- Similarity between pairs, to a lesser extent, is also observed in the baryon-antibaryon case

## Possible explanations:

- Fermi-Dirac Quantum Statistics? **NO (non-identical particles)**
- Coulomb repulsion? **NO (uncharged particles)**
- Strong Final-State Interactions? **NO (checked)**

# Toy Monte Carlo

## CALM – ConservAtion Laws Model

### ALICE exp data

(a) proton like-sign pairs

### MC only mom. cons.

Toy Monte Carlo Events  
with momentum conservation only

Strong suppression of any other effects?  
What is the underlying mechanism?

# $\Delta\eta\Delta\phi$ of baryons

Małgorzata Janik, ŁG

Eur.Phys.J. C77 (2017) 8, 569

- None of studied MC models (PYTHIA, PHOJET, EPOS, HERWIG) agrees with the data even qualitatively

The same effect in other analyses?

**Femtoscscopy**

# Non-femtoscopic correlations

• Non-femtoscopic correlations visible in small systems for **pions** and **kaons**:

- Grow with increasing  $k_T$
- Grow with decreasing multiplicity
- **Significant source of systematics in the fitting procedure**
- So far only hypothesis of (mini-)jet origin
- How do baryon correlations look like in pp?

$$k_T = |p_{T1} + p_{T2}|/2$$

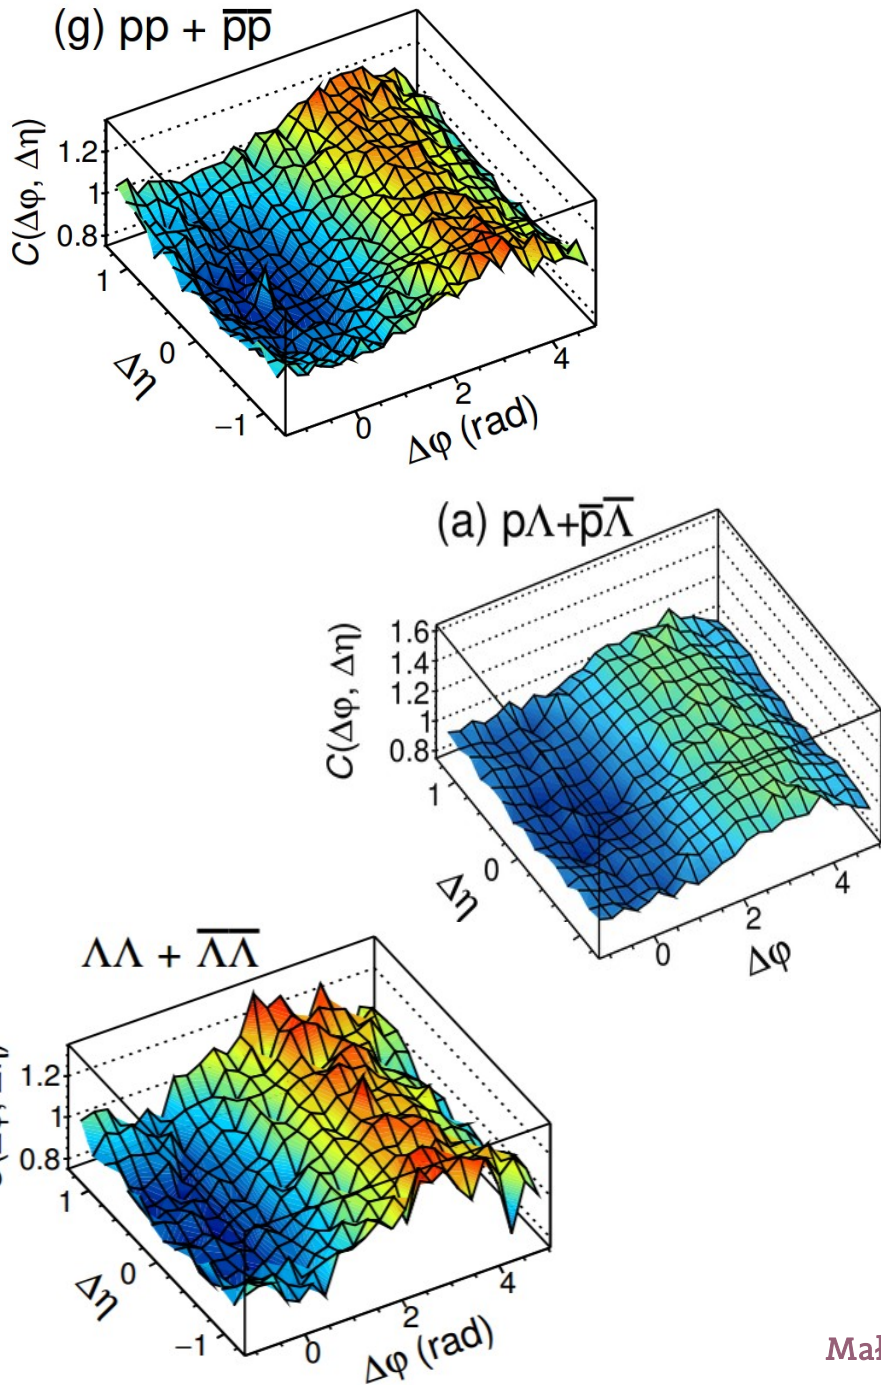

arXiv:1502.00559

arXiv:1101.3665

# Comparison of angular and femto corr. fun.

**Non-femto  
NOT PRESENT  
for all bb systems**

**Non-femto  
STRONG  
for all bb systems**

# Possible origin of the small peak

# Femto correlations of protons

Possible origin of the small peak: QS(Fermi-Dirac)  
+Coulomb+Strong

- Visible in femtosopic correlation function
- Dominant effect around  $q_{\text{inv}} = 0.04 \text{ GeV}/c$
- **Strong interaction** the only source of positive correlation for baryons

PRC 92 (2015) 054908

# Femto correlations of protons

Małgorzata Janik, ŁG

- Direct transformation from  $C(q_{inv})$  to  $C(\Delta\eta\Delta\phi)$  not possible
- One can use a simple Monte Carlo procedure:
  - generate random  $\eta$  and  $\phi$  values from uniform distributions (for 2 particles:  $\eta_1, \eta_2, \phi_1, \phi_2$ )
  - generate random  $p_T$  value from measured  $p_T$  distribution (for 2 particles:  $p_{T1}, p_{T2}$ )
  - calculate  $q_{inv}$  from generated  $\eta_1, \eta_2, \phi_1, \phi_2, p_{T1}$  and  $p_{T2}$  (the longest step)
  - randomly select  $q_{inv}$  and take a corresponding value from measured femtoscopic correlation and apply it as a weight while filling the numerator of  $\Delta\eta\Delta\phi$  correlation

ALI-PREL-121697

# Femto correlations of protons

Małgorzata Janik, ŁG

## Results:

- Femto correlation produces spike at  $(\Delta\eta, \Delta\phi) = (0, 0)$
- Comparison of two peaks: 1-bin wide projection on  $\Delta\phi$  (subtract minimum)
- Both the height and the width of two peaks comparable
- Strong interaction does not cause the wide depletion

(a) Measured pp  $\Delta\eta\Delta\phi$  corr. fctn

(b) Transformed  $\Delta\eta\Delta\phi$  corr. fctn

(c) Projection of measured corr. fctn.

(d) Comparison of projections
