Outline

- Goal
- e-cloud simulation setup
- SEY threshold
- Heat load versus offset
- Current vs offset
- Energy spectra
- Current distribution
- Electron density animation
- Summary

Outline

- **Goal**
- e-cloud simulation setup
- SEY threshold
- Heat load versus offset
- Current vs offset
- Energy spectra
- Current distribution
- Electron density animation
- Summary

Goal

- To study the electron cloud build-up process and its dependence on **beam position, SEY** and **beam intensity**
- Especially the **heat load** and **current** deposited on the chamber walls were studied

Outline

- Goal
- **e-cloud simulation setup**
- SEY threshold
- Heat load versus offset
- Current vs offset
- Energy spectra
- Current distribution
- Electron density animation
- Summary

e-cloud simulation setup

- 25 ns bunch spacing
- 450 GeV beam energy
- $\beta_x = \beta_y = 100$ m
- No magnetic field
- Uniform initial electron density
- SEY scan: 1.0 - 2.9
- Intensity scan: $0.5 - 2.5 \times 10^{11}$ p/bunch
- Beam offset scan: 0 - 18 mm
- Chamber diameter: 42 mm

Outline

- Goal
- e-cloud simulation setup
- **SEY threshold**
- Heat load versus offset
- Current vs offset
- Energy spectra
- Current distribution
- Electron density animation
- Summary

SEY threshold

- At zero offset the SEY threshold is larger for higher intensities
- For SEYs of 1.4 or lower, no simulations show multipacting

SEY threshold

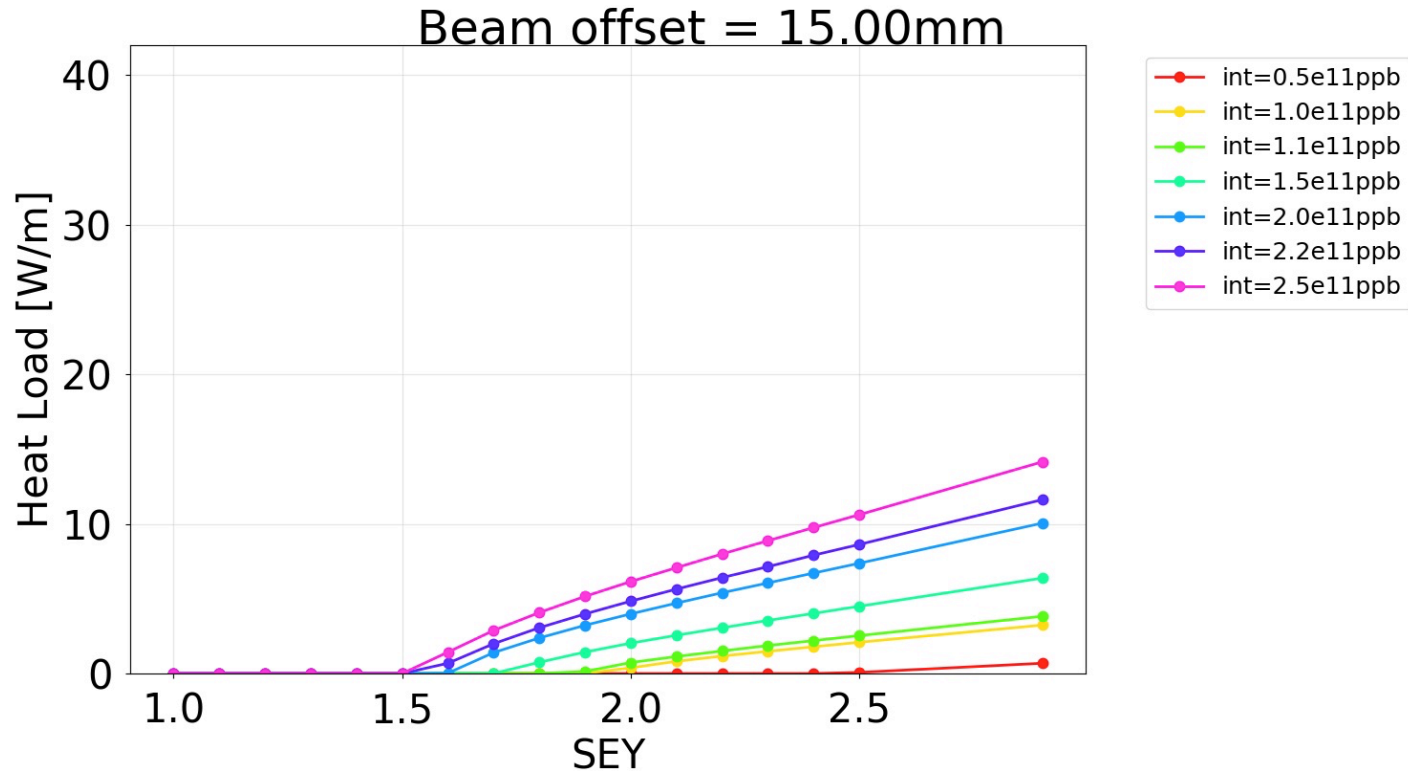

- At zero offset the SEY threshold is larger for higher intensities
- As the offset is increased the thresholds move

SEY threshold

- At zero offset the SEY threshold is larger for higher intensities
- As the offset is increased the thresholds move

SEY threshold

- At zero offset the SEY threshold is larger for higher intensities
- As the offset is increased the thresholds move
- Eventually the situation is reversed

Outline

- Goal
- e-cloud simulation setup
- SEY threshold
- **Heat load versus offset**
- Current vs offset
- Energy spectra
- Current distribution
- Electron density animation
- Summary

Heat load versus offset

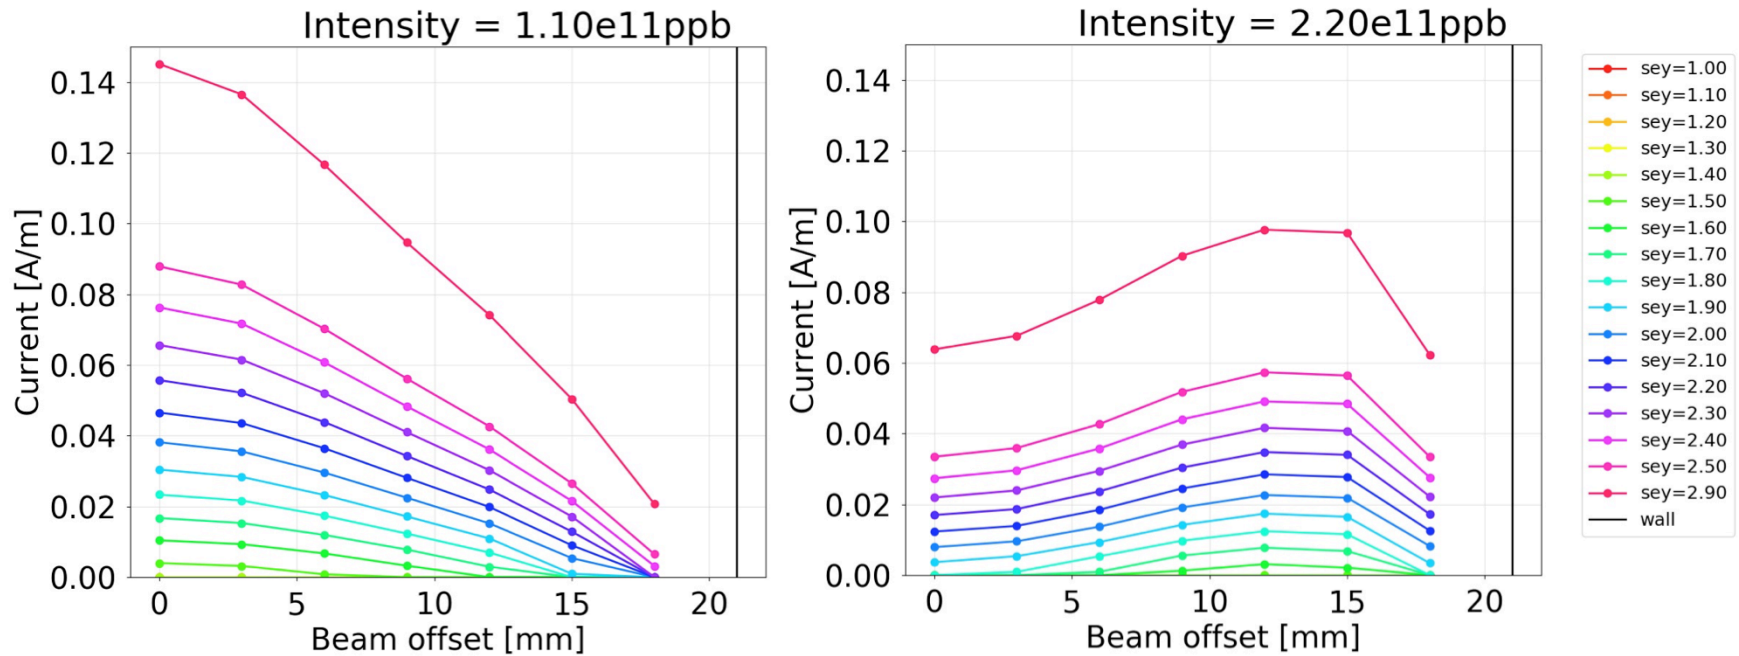

- At beam intensity 1.1×10^{11} p/bunch the heat load always decreases when the offset increases
- At beam intensity 2.2×10^{11} p/bunch this is not always the case
- For SEYs of 2.5 or lower the maximum heat load occurs at a non-zero beam offset

Outline

- Goal
- e-cloud simulation setup
- SEY threshold
- Heat load versus offset
- **Current vs offset**
- Energy spectra
- Current distribution
- Electron density animation
- Summary

Current vs offset

- For beam intensity of 1.1×10^{11} p/bunch the current always decreases as the offset increases
- For beam intensity 2.2×10^{11} p/bunch the maximum current occurs at a non-zero beam offset
- No multipacting for SEYs of 1.4 or lower

Comparing heat load and current

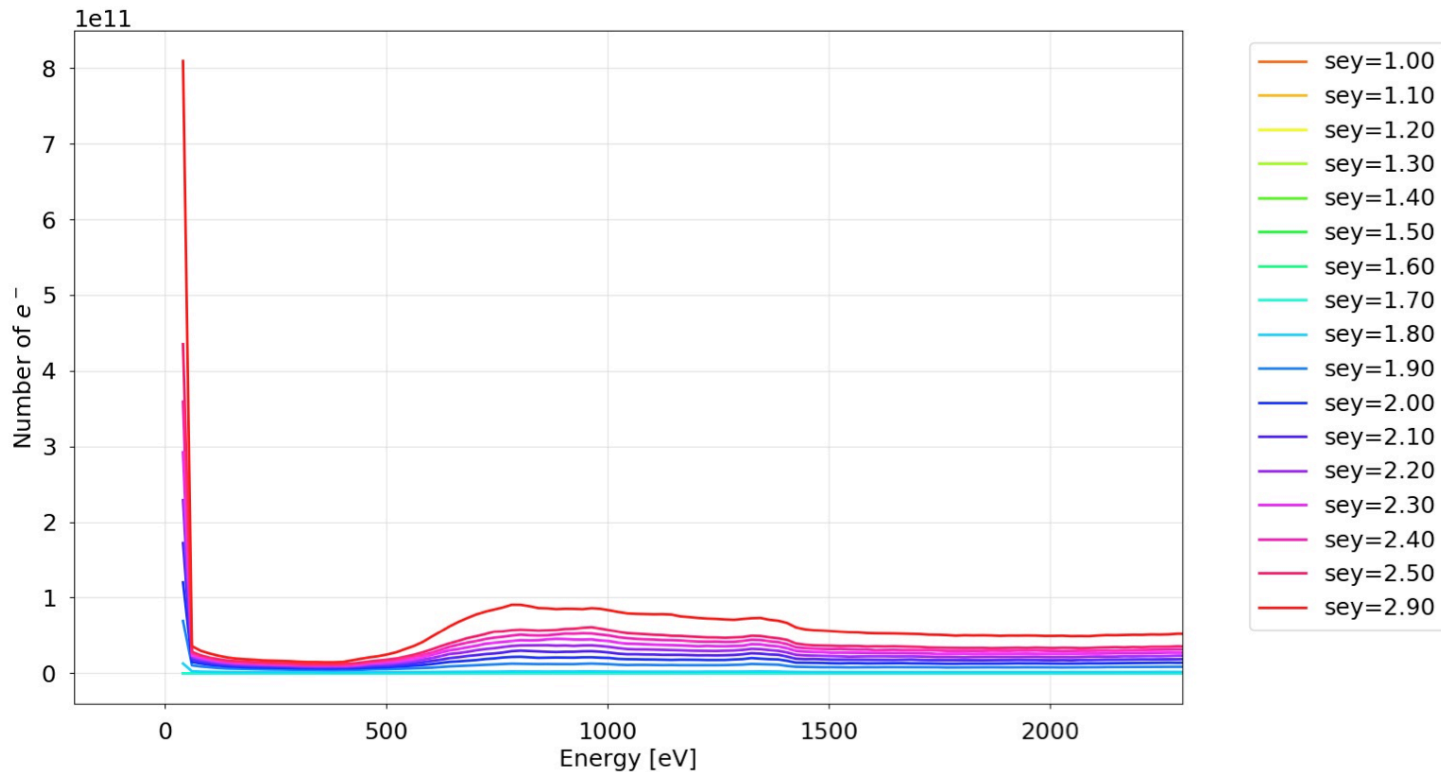

- Their maxima occur at different beam offsets, especially for large SEY values
- This means that there are fewer but more energetic electrons impacting the chamber at smaller offsets

Outline

- Goal
- e-cloud simulation setup
- SEY threshold
- Heat load versus offset
- Current vs offset
- **Energy spectra**
- Current distribution
- Electron density animation
- Summary

Energy spectra

offset=3.00mm, int=2.20e11ppb

- The energy spectra shows electrons moving from higher to lower energy as the beam offset increases

Energy spectra

offset=6.00mm, int=2.20e11ppb

- The energy spectra shows electrons moving from higher to lower energy as the beam offset increases

Energy spectra

offset=9.00mm, int=2.20e11ppb

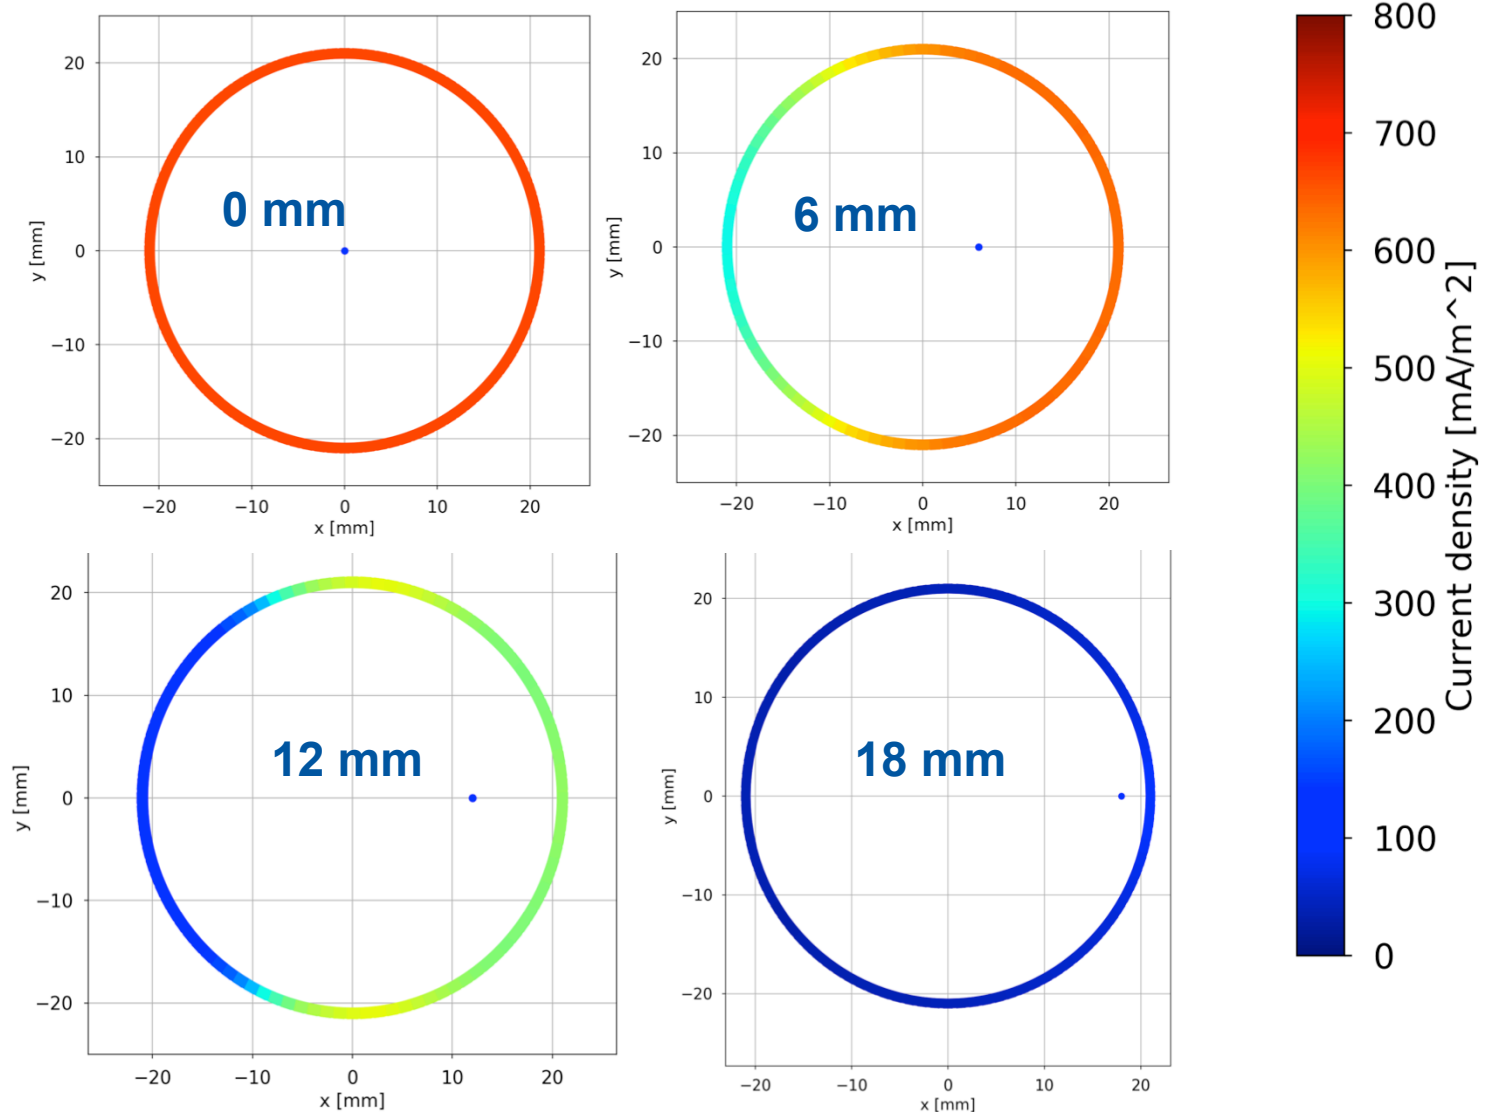

- The energy spectra shows electrons moving from higher to lower energy as the beam offset increases

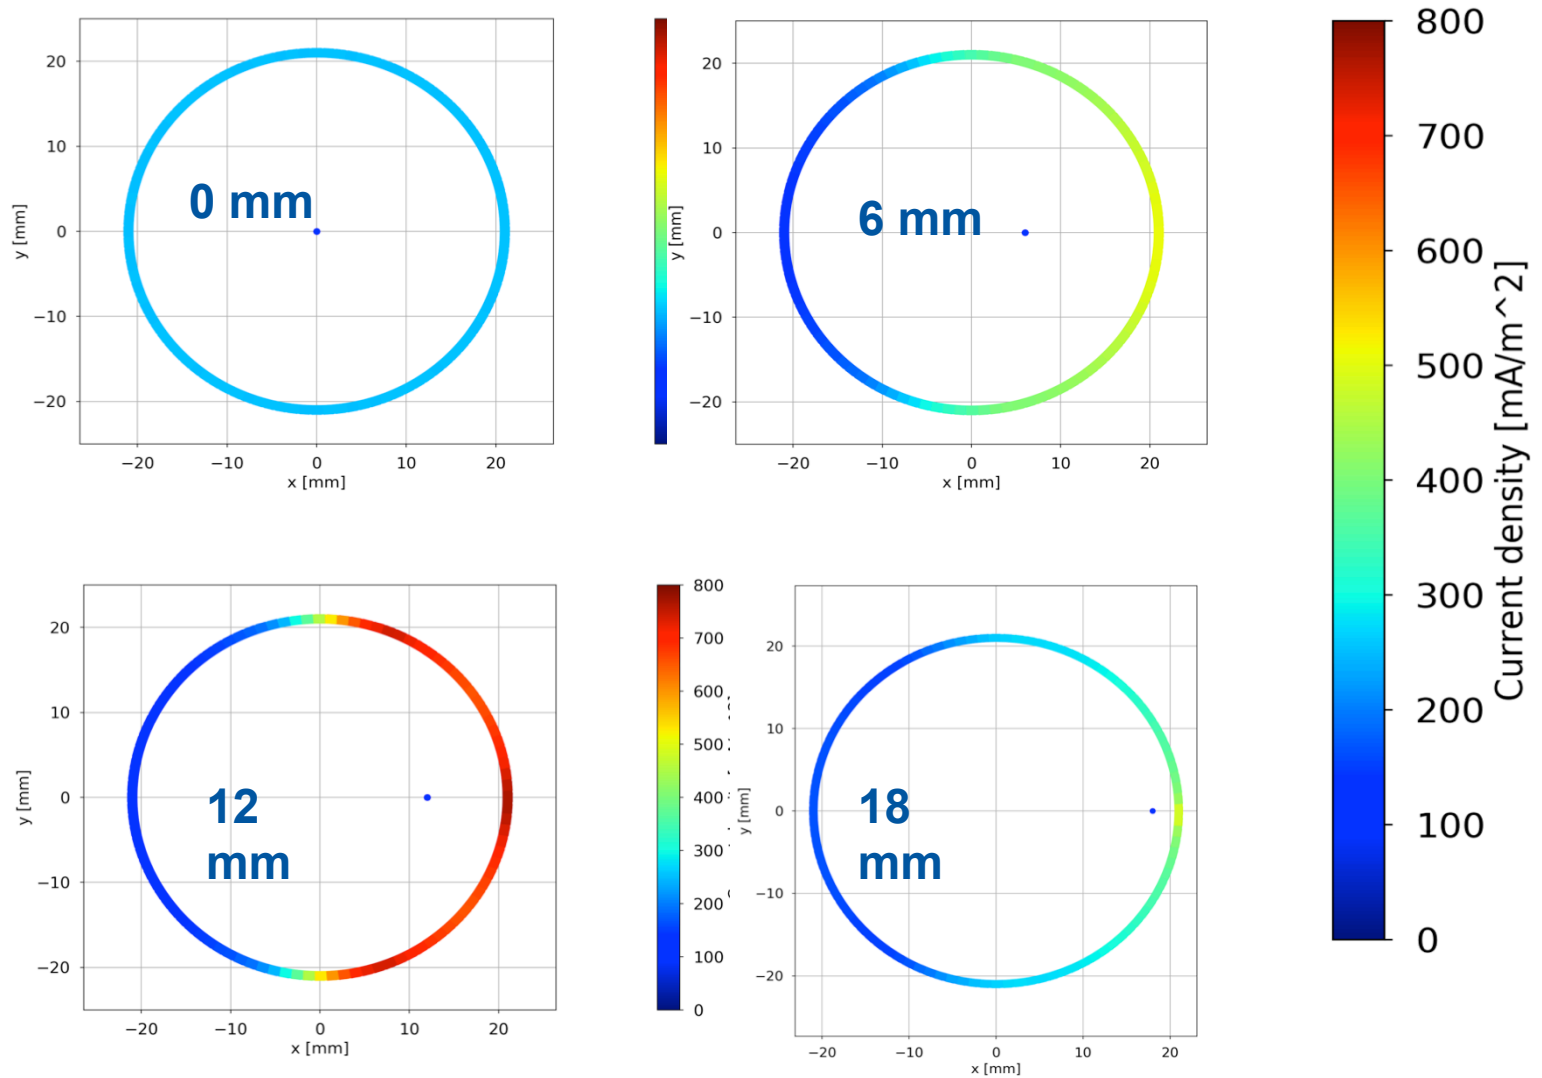

Outline

- Goal
- e-cloud simulation setup
- SEY threshold
- Heat load versus offset
- Current vs offset
- Energy spectra
- **Current distribution**
- Electron density animation
- Summary

Current distribution 1.1×10^{11} p/bunch

Current distribution, 2.2×10^{11} p/bunch

The SEY curve

- The SEY depends on the energy of the impacting electrons
- The SEY curve can explain the differences in current simulated at different intensities

Electron density animation

Intensity = $1.1e11$ ppb
SEY = 2.5
Offset = 12 mm

Summary

- The dependence of e-cloud build-up on beam position was studied
- For SEYs of 1.4 or lower, no simulations showed multipacting
- The SEY threshold depends on the beam position as well as the beam intensity
- At high intensities the heat load and the current have their maxima at different beam offsets
- The current distribution on the chamber wall depends on both beam intensity and beam position
