

Simulation studies of the bunch length dependence on e-cloud build-up in circular drift tubes

Eric Wulff

Outline

- Goal
- e-cloud simulation setup
- SEY threshold
- Heat load and current vs bunch length
- Summary

Outline

- **Goal**
- e-cloud simulation setup
- SEY threshold
- Heat load and current vs bunch length
- Summary

Goal

- To study the dependence of bunch length on the heat load and current deposited on a circular drift tube of radius 40 mm

Outline

- Goal
- **e-cloud simulation setup**
- SEY threshold
- Heat load and current vs bunch length
- Summary

e-cloud simulation setup

- 450 GeV beam energy
- 1.1×10^{11} p/bunch beam intensity
- Standard 25 ns beam
- No magnetic field
- Uniform initial electron density
- SEY scan: 1.0 - 1.8
- Bunch length scan: 0.7 - 1.8 ns
- Circular chamber with radius of 40mm

Outline

- Goal
- e-cloud simulation setup
- **SEY threshold**
- Heat load and current vs bunch length
- Summary

SEY threshold

- The SEY threshold is 1.4 for all simulated bunch lengths

SEY threshold

- The SEY threshold is 1.4 no matter which bunch length is used

Outline

- Goal
- e-cloud simulation setup
- SEY threshold
- **Heat load and current vs bunch length**
- Summary

Current vs bunch length

- The current is increasing linearly with the bunch length

Heat load vs bunch length

- For low SEYs the HL increases with growing bunch lengths
- For high SEYs it decreases instead

Outline

- Goal
- e-cloud simulation setup
- SEY threshold
- Heat load and current vs bunch length
- **Summary**

Summary

- The SEY threshold is 1.4 for all bunch lengths in the range 0.7-1.8 ns according to simulations
- The current is increasing linearly with the bunch length
- For low SEYs the heat load increases with increasing bunch length
- For high SEYs it decreases instead
