Going forward with theory

Janusz Gluza

11th FCC-ee workshop: Theory and Experiments

CERN, 11 January 2019
STANDARD MODEL
SM precision parameters determination: $\alpha(M_Z^2)$

1. $\alpha(M_Z^2)$ in precision physics (precision physics limitations)

Uncertainties of hadronic contributions to effective $\alpha$ are a problem for electroweak precision physics: besides top Yukawa $y_t$ and Higgs self-coupling $\lambda$

- $\alpha$, $G_\mu$, $M_Z$ most precise input parameters $\Rightarrow$ precision predictions
  - $\sin^2\Theta_f, v_f, a_f, M_W, \Gamma_Z, \Gamma_W, \cdots$

50% non-perturbative

- $\alpha(M_Z), G_\mu, M_Z$ best effective input parameters for VB physics (Z,W) etc.

\[
\begin{align*}
\frac{\delta \alpha}{\delta G_\mu} & \sim 3.6 \times 10^{-9} \\
\frac{\delta G_\mu}{G_\mu} & \sim 8.6 \times 10^{-6} \\
\frac{\delta M_Z}{M_Z} & \sim 2.4 \times 10^{-5} \\
\frac{\delta \alpha(M_Z)}{\alpha(M_Z)} & \sim 0.9 \div 1.6 \times 10^{-4} \quad \text{(present: lost $10^5$ in precision!)} \\
\frac{\delta \alpha(M_Z)}{\alpha(M_Z)} & \sim 5.3 \times 10^{-5} \quad \text{(FCC – ee/ILC requirement)}
\end{align*}
\]

**LEP/SLD:** $\sin^2\Theta_{\text{eff}} = (1 - v_l/a_l)/4 = 0.23148\pm 0.00017$

$\delta \Delta \alpha(M_Z) = 0.00020 \quad \Rightarrow \quad \delta \sin^2\Theta_{\text{eff}} = 0.00007$ ; $\delta M_W/M_W \sim 4.3 \times 10^{-5}$

affects most precision tests and new physics searches!!!

\[
\frac{\delta M_W}{M_W} \sim 1.5 \times 10^{-4}, \quad \frac{\delta M_H}{M_H} \sim 1.3 \times 10^{-3}, \quad \frac{\delta M_t}{M_t} \sim 2.3 \times 10^{-3}
\]

For pQCD contributions very crucial: precise QCD parameters $\alpha_s, m_c, m_b, m_t \rightarrow \text{Lattice-QCD}$

F. Jegerlehner
FCCee Workshop, CERN Geneva, January 2019
SM precision parameters determination: $\alpha(M_Z^2)$

Still an issue in HVP

- region 1.2 to 2 GeV data; test-ground exclusive vs inclusive $R$
  measurements (more than 30 channels!) VEPP-2000 CMD-3, SND (NSK)
  scan, BaBar, BES III radiative return! still contributes 50% of uncertainty

Illustrating progress by BaBar and NSK exclusive channel data
vs new inclusive data by KEDR. Why point at 1.84 GeV so high?
SM precision parameters determination: $\alpha(M_Z^2)$

2. Reducing uncertainties via the Euclidean split trick:
   Adler function controlled pQCD

- experiment side: new more precise measurements of $R(s)$
- theory side: $\alpha_{em}(M_Z^2)$ by the "Adler function controlled" approach

\[
\alpha(M_Z^2) = \alpha^{\text{data}}(-s_0) + \left[ \alpha(-M_Z^2) - \alpha(-s_0) \right]^{\text{pQCD}} + \left[ \alpha(M_Z^2) - \alpha(-M_Z^2) \right]^{\text{pQCD}}
\]

- data
- pQCD Adler
- pQCD HVP

- the space-like $-s_0$ is chosen such that pQCD is well under control for $-s < -s_0$; offset $\alpha^{\text{data}}(-s_0)$ integrated $R(s)$ data

- the Adler function is i) the monitor to control the applicability of pQCD and
  ii) pQCD part $\left[ \alpha(-M_Z^2) - \alpha(-s_0) \right]^{\text{pQCD}}$ by integrated Adler function $D(Q^2)$

- small remainder $\left[ \alpha(M_Z^2) - \alpha(-M_Z^2) \right]^{\text{pQCD}}$ by calculation of VP function $\Pi'_\gamma(s)$
Conclusion: 3 approaches should be further explored for better error estimate

Note: **theory-driven** standard analyses ($R(s)$ integral) using pQCD above 1.8 GeV cannot be improved by improved cross-section measurements above 2 GeV !!!

<table>

Adler function method is competitive with **Patrick Janot's** direct near $Z$ pole determination via forward backward asymmetry in $e^+e^- \rightarrow \mu^+\mu^-$

$$A_{FB}^{\mu\mu} = A_{FB,0}^{\mu\mu} + \frac{3 a^2}{4 v^2} \frac{I}{Z + G}$$

where

- $\gamma - Z$ interference term: $I \propto \alpha(s) G_{\mu}$
- $Z$ alone: $Z \propto G_{\mu}^2$
- $\gamma$ only: $G \propto \alpha^2(s)$
- $v$ vector $Z$ coupling also depends on $\alpha(s \sim M_Z^2)$ and $\sin^2 \Theta_f(s \sim M_Z^2)$
- $a$ axial $Z$ coupling sensitive to $\rho$-parameter (strong $M$, dependence)

- using $v, a$ as measured at $Z$-peak
**W-pair production**

**Success story at LEP2:**

- $\sigma_{WW}$: 1%-level agreement with NLO theory
  - test of EW-sector of SM at quantum level
- measurement of branching ratios (lepton universality)
  - bounds on anomalous triple vector-boson couplings
  - test of non-abelian structure
- **W-mass measurement** from kinematic reconstruction
  - ($\sigma_{WW}$ at threshold)

![Graph showing $\sigma_{WW}$ vs. GeV with data points and curves.](image)
FCC-ee study:  

- single point \( \sqrt{s} = 161.4 \text{ GeV} \)
  \[ \Delta M_W \simeq 0.25 \text{ MeV} \]
  with 15 ab\(^{-1}\) if
  \[ \delta \sigma_{WW}^{\text{th}} < 0.6 \text{ fb}(\approx 0.01\%) \]
- simultaneous fit
  \[ \Delta M_W \simeq 0.41 \text{ MeV}, \Delta \Gamma_W \simeq 1.10 \text{ MeV} \]
  from two points
  \[ \sqrt{s} = 157.5, 162.3 \text{ GeV} \]

CEPC study:  

- 3 points
  \[ \sqrt{s} = 157.5, 161.5, 162.3 \text{ GeV} \]
  with 2.6 ab\(^{-1}\)
  \[ \Delta M_W \simeq 1 \text{ MeV}, \Delta \Gamma_W \simeq 2.8 \text{ MeV} \]
Beyond threshold: anomalous gauge couplings at $\sqrt{s} = 240$ GeV

- traditional TGC parameters $g_1^Z$, $\kappa_{Z/\gamma}$, $\lambda_{Z/\gamma}$ related to coefficients of $D = 6$ operators, $\mathcal{L}_{D=6} = \sum_i \frac{\alpha_s}{N_c} O_i$

- recent EFT calculations of $e^-e^+ \rightarrow W^-W^+$ and analysis of LEP2 data (Buchalla et al. 13; Wells/Zhang 15; Berthier et al. 16)

- some $O_i$ affect both Higgs and EW measurements
  $\Rightarrow$ consistent EFT fit of FCC-ee data required
  (talks by Das Bakshi, You, de Blas)

- Effect of non-universal EW corrections similar to size of TGCs accessible at LEP2
  (Denner et al. 01)

$\Rightarrow$ NNLO EW for $e^-e^+ \rightarrow W^-W^+$ required for FCC-ee accuracy
NLO corrections near threshold

\[ s - 4M_W^2 \sim M_W \Gamma_W \Rightarrow \beta \sim \sqrt{\Gamma_W/M_W} \sim \alpha^{1/2} \]

Schematic structure of NLO corrections to total cross section:

\[ \Delta^{(1)}\sigma_{WW \rightarrow 4f}|_{s \approx 4M_W^2} \propto \beta \alpha \left[ \frac{1}{\beta} + \ln \beta \ln \left( \frac{m_e}{M_W} \right) + \ln \left( \frac{m_e}{M_W} \right) + C^{(1)} \right] + \text{const} + \mathcal{O}(\beta) \]

Enhanced corrections in threshold limit

- **mass logarithms** \( \ln \left( \frac{m_e}{M_W} \right) \): resum in ISR structure function

- **Coulomb corrections** \( \sim \alpha/\beta \sim \text{screened by finite } W \text{-width} \)
  \[ \Rightarrow \text{Coulomb corrections} \sim \alpha^n (M_W/\Gamma_W)^{n/2} \sim \alpha^{n/2} \]
  enhanced but resummation not necessary
  (Method for all-order resummation known \( \Rightarrow \text{ii} \))

- **soft \( \ln \beta \)** corrections \( \sim \alpha \ln \alpha \sim 0.04 \)
  \[ \Rightarrow \text{resummation not necessary} \]
**Full NLO calculation** for $e^+e^- \to 4f$  
(Denner, Dittmaier, Roth, Wieders 05)

- More than 1000 1-loop diagrams, 5, 6-point loop integrals
- Pioneering methods for six-point diagrams
  now automated for LHC: RECOLA, OpenLoops, MadLoops
- Complex mass scheme for $W$ decay width
- Fully differential calculation
- Not easy to incorporate higher-order effects
- DPA not sufficient at threshold and for $\sqrt{s} > 500$ GeV

---

C. Schwinn  
**WW** threshold theory  
FCC-ee workshop
EFT expansion in $\alpha \sim \frac{\Gamma_W}{M_W} \sim \beta^2$  
(Beneke/Falgari/CS/Signer/Zanderighi 07)

- systematically possible to include higher-order corrections
- limited to total cross section near threshold

Leading NNLO corrections

- 2nd Coulomb correction $\sim \alpha^2/\beta^2 \sim \alpha$  
  (Fadin et al. 95)
- Coulomb-enhanced corrections $\sim \alpha^2/\beta \sim \alpha^{3/2}$  
  (Actis et al. 08)

- Numerical effect: $\Delta \sigma_{WW} \sim 5\%$; $[\delta M_W] \lesssim 3\text{ MeV}$

WW threshold theory  
FCC-ee workshop
Future improvements of theory predictions?

Implementation of state-of-the art calculations in public tools?

- **NLO-EW** $e^-e^+ \rightarrow 4f$ now possible with standard tools
  
  (RECOLA, OpenLoops, Madloops + SHERPA, MadGraph, WHIZARD...)

  but not (yet) optimized for $e^-e^+$ (ISR, Beamstrahlung)

- **Two-loop Coulomb-enhanced** corrections for differential observables doable; (related: $t\bar{t}$ with Coulomb resummation in WHIZARD)

  (no guarantee of formal accuracy for general distributions)

**Full NNLO** in EFT for total cross section

- Soft $\log \beta$ terms can be adapted from QCD results

- NNLO $\log(m_e/M_W)$ terms doable (c.f. Bhabha scattering)

- two-loop hard non-logarithmic corrections

  (from amplitudes for $e^+e^- \rightarrow W^+W^-$ at threshold: border of current capabilities)

  resulting uncertainty from cross-section calculation

  $$\Delta \sigma_{\text{hard}}^{(2)} = \left( \frac{\alpha}{2\pi} \right)^2 c^{(2)} \sigma^{(0)} \sim (1 - 2)\%$$

  for estimate $c^{(2)} = (c^{(1)})^2$

**Full NNLO** for $e^+e^- \rightarrow 4f$: completely new methods needed
Conclusions and outlook

- KoralW+YFSWW3: LEP2 precision is 0.5%.
  Factor of 20 ÷ 50 improvement is needed for FCCee
- Lesson from LEP2: be pragmatic, split into Double- and Single-Pole, pick only numerically dominant terms:
  - $O(\alpha^1)$ for $e^- e^+ \rightarrow 4f$ must be implemented in MC with explicit split into Double Pole and Single Pole. Calculations exist
  - $O(\alpha^2)_{DP}$ calculations for the Double-Pole production and decay parts are needed! Feasible?
  - $O(\alpha^2)_{SP}$ and $O(\alpha^3)$ seem to be negligible

- More detailed analysis at the threshold may be instrumental
  - EFT methods promising, but for now inclusive results only
  - Non-factorizable soft interferences can be exponentiated within YFS scheme. How much of the higher order corrs. would be reproduced this way?

The overall precision tag $\sim 2 \times 10^{-4}$ feasible (?)

YFSWW3+KoralW with new exponentiation
look like a good starting point

\]

[Beneke, Marquard, Nason, Steinhauser’16]
MC Top Quark Mass Parameter

Why is there a non-trivial issue in the interpretation of $m_t^{MC}$?

- picture of “top quark particle” does not apply (non-zero color charge)

- $m_t$ is a scheme-dependent parameter of a perturbative computation
  → in which scheme do MC event generators calculate?

- relation of $m_t^{MC}$ to any field theory mass definition can be affected by different contributions (let’s consider pole mass just for convention)

\[
m_t^{MC} = m_t^{pole} + \Delta_m^{pert} + \Delta_m^{non-pert} + \Delta_m^{MC}
\]

- pQCD contribution:
  - perturbative corrections
  - depends on MC parton shower setup

- non-perturbative contribution:
  - effects of hadronization model
  - may depend on parton shower setup

- Monte Carlo shift:
  - contribution arising from systematic MC uncertainties
  - e.g. color reconnection, b-jet modelling, finite width,...
  - should be covered by “MC uncertainty” or better negligible

this talk
Conclusions/Outlook

• for angular ordered parton showers (Herwig) one can derive the perturbative contributions between generator mass and pole masse ($\Delta_m^{\text{pert}}$)

$$m_{\text{CB}}(Q_0) = m^{\text{pole}} - \frac{2}{3} \alpha_s(Q_0) Q_0 + \mathcal{O}(\alpha_s^2)$$

this corresponds the pole of the quark propagator in presence of a shower cut

• current restrictions:
  ▶ boosted top quarks
  ▶ narrow width approximation
  ▶ top production (2-jettiness)

needed to remove restriction:
  → parton shower algorithm for slow tops
  → parton shower for unstable tops
  → factorized predictions including top decay

• for all three new conceptual developments are required (w.i.p.)

• study of non-perturbative contributions to the relation between generator mass and pole mass ($\Delta_m^{\text{non-pert}}$) can be carried out by dedicated MC simulations (w.i.p.)

• numerical calibration still important tool for consistency checks
Comparison with Herwig

- $Q=700\text{ GeV}, \Lambda=1.0\text{ GeV}$
- $Q=700\text{ GeV}, \Lambda=3.0\text{ GeV}$
- $Q=1000\text{ GeV}, \Lambda=1.0\text{ GeV}$
- $Q=1000\text{ GeV}, \Lambda=3.0\text{ GeV}$

SM FCC-ee-t, Daniel Samitz, shower cuts dependence

Modular elliptic curves and Fermat’s Last Theorem

By Andrew John Wiles*

For Nada, Claire, Kate and Olivia

*Cubum autem in duos cubos, aut quadratoquadatum in duos quadratoquadratos, et generaliter nullam in infinitum ultra quadratum potestatum in duos ejusdem nominis fas est dividere: cujes rei demonstrationem mirabilem sane detexi. Hanc marginis exiguitas non caperet.
Feynman integrals and iterated integrals of modular forms

Luise Adams and Stefan Weinzierl

In this paper we show that certain Feynman integrals can be expressed as linear combinations of iterated integrals of modular forms to all orders in the dimensional regularisation parameter $\varepsilon$. We discuss explicitly the equal mass sunrise integral and the kite integral. For both cases we give the alphabet of letters occurring in the iterated integrals. For the sunrise integral we present a compact formula, expressing this integral to all orders in $\varepsilon$ as iterated integrals of modular forms.
Progress in numerical approaches

Numerical evaluation of the dilogarithm

The dilogarithm:

\[ \text{Li}_2(x) = \int_0^x \frac{dt_1}{t_1} \int_0^{t_1} \frac{dt_2}{1-t_2} = \sum_{n=1}^{\infty} \frac{x^n}{n^2} \]

Map into region \(|x| \leq 1\) and \(-1 \leq \text{Re}(x) \leq 1/2\), using

\[ \text{Li}_2(x) = -\text{Li}_2 \left( \frac{1}{x} \right) - \frac{\pi^2}{6} - \frac{1}{2} \left( \ln(-x) \right)^2, \quad \text{Li}_2(1-x) = -\text{Li}_2(1-x) + \frac{\pi^2}{6} - \ln(x) \ln(1-x). \]

Acceleration using Bernoulli numbers \(B_j\):

\[ \text{Li}_2(x) = \sum_{j=0}^{\infty} \frac{B_j}{(j+1)!} (-\ln(1-x))^{j+1}, \]

'I Hooft, Veltman, '79
Progress in numerical approaches

Diagrams

There are three Feynman diagrams contributing to the two-loop electron self-energy in QED with a single fermion:

All master integrals are (sub-) topologies of the kite graph:

One sub-topology is the sunrise graph with three equal non-zero masses:
Progress in numerical approaches

**Iterated integrals**

For \( \omega_1, \ldots, \omega_k \) differential 1-forms on a manifold \( M \) and \( \gamma: [0, 1] \to M \) a path, write for the pull-back of \( \omega_j \) to the interval \([0, 1]\)

\[
 f_j(\lambda) \, d\lambda = \gamma^* \omega_j.
\]

The **iterated integral** is defined by (Chen '77)

\[
 I_\gamma(\omega_1, \ldots, \omega_k; \lambda) = \int_0^{\lambda} d\lambda_1 f_1(\lambda_1) \int_0^{\lambda_1} d\lambda_2 f_2(\lambda_2) \cdots \int_0^{\lambda_{k-1}} d\lambda_k f_k(\lambda_k).
\]

**Example 1:** Multiple polylogarithms (Goncharov '98)

\[
 \omega_j = \frac{d\lambda}{\lambda - z_j}.
\]

**Example 2:** Iterated integrals of modular forms (Brown '14): \( f_j(\tau) \) a modular form,

\[
 \omega_j = 2\pi i f_j(\tau) \, d\tau.
\]
Progress in numerical approaches

Iterated integrals of modular forms

Modular forms have a $q$-expansion. Using

$$2\pi i \, d\tau = \frac{dq}{q}$$

we may integrate term-by-term and obtain the $q$-expansion of the master integrals.

For example, for the $\epsilon^2$-term of the sunrise integral one finds

$$I_{6}^{(2)} = 3 \text{Cl}_2 \left( \frac{2\pi}{3} \right) - 3 \sqrt{3} \left[ q - \frac{5}{4} q^2 + q^3 - \frac{11}{16} q^4 + \frac{24}{25} q^5 - \frac{5}{4} q^6 + \frac{50}{49} q^7 - \frac{53}{64} q^8 + q^9 \right] + O(q^{10})$$

We may truncate the $q$-series and evaluate the resulting polynomial numerically.
Progress in numerical approaches

We defined $q_0$ such that $q_0 = 0$ for $x = 0$.

For which values $x \in \mathbb{R}$ do we have $|q_0| < 1$?

We have $|q_0| < 1$ for $x \in \mathbb{R}\ \{1, 9, \infty\}$.

3. Conclusions
Progress in numerical approaches

“Vacuum” subtraction

1. $J(q^2) = \frac{1}{(q^2 - M^2)^2}$
2. $q^2 \xrightarrow{GP} \bar{q}^2 := q^2 - \mu^2$
3. $J(q^2) \xrightarrow{GP} \bar{J}(\bar{q}^2) := \frac{1}{(\bar{q}^2 - M^2)^2}$

$$\frac{1}{(\bar{q}^2 - M^2)^2} = \frac{1}{q^2} + \left( \frac{M^2}{\bar{q}^2(\bar{q}^2 - M^2)^2} + \frac{M^2}{\bar{q}^4(\bar{q}^2 - M^2)} \right)$$

Vacuum

$$\int [d^4q] \frac{1}{(\bar{q}^2 - M^2)^2} := \lim_{\mu \to 0} \int d^4q \left( \frac{M^2}{\bar{q}^2(\bar{q}^2 - M^2)^2} + \frac{M^2}{\bar{q}^4(\bar{q}^2 - M^2)} \right)$$
Progress in numerical approaches

Two core tenets of QFT

1. Gauge invariance

   - FDR integrals are invariant under the shift $q \rightarrow q + p \ \forall p$
   - Cancellations if $q^2 \xrightarrow{GP} \bar{q}^2$ in the numerator

   $$\int [d^4q] \frac{q^2}{q^2(\bar{q}^2 - M^2)^2} = \int [d^4q] \frac{1}{(q^2 - M^2)^2}$$

   \(\Rightarrow\) One can prove graphical WI in QFT

2. Unitarity of $S = I + iT$

   - It requires $i(T - T^\dagger) = -T^\dagger T$
Progress in numerical approaches

Our observable

\[ \sigma_B \propto \int d\Phi_n \sum_{\text{spin}} |A_n^{(0)}|^2 \]

\[ \sigma_V \propto \int d\Phi_n \sum_{\text{spin}} \left\{ A_n^{(2)}(A_n^{(0)})^* + A_n^{(0)}(A_n^{(2)})^* \right\} \]

\[ \sigma_R \propto \int d\Phi_{n+2} \sum_{\text{spin}} \left\{ A_{n+2}^{(0)}(A_{n+2}^{(0)})^* \right\} \]

\[ \sigma^{\text{NNLO}} = \sigma_B + \sigma_V + \sigma_R \]

In particular

\[ \Gamma^{\text{NNLO}}(H \to b\bar{b}) \quad \text{and} \quad \sigma^{\text{NNLO}}_{\gamma^* \to \text{jets}} \]

Progress in analytical/numerical approaches

**OPP AT TWO LOOPS**

- Write the "OPP-type" equation at two loops

\[
\frac{N(l_1, l_2; \{p_i\})}{D_1 D_2 \ldots D_n} = \sum_{m=1}^{\min(n,8)} \sum_{S_{m,n}} \frac{\Delta_{i_1 i_2 \ldots i_m}(l_1, l_2; \{p_i\})}{D_{i_1} D_{i_2} \ldots D_{i_m}}
\]

\[
\sum \frac{\Delta_{i_1 i_2 \ldots i_m}(l_1, l_2; \{p_i\})}{D_{i_1} D_{i_2} \ldots D_{i_m}} \to \text{spurious } \oplus \text{ ISP } - \text{ irreducible integrals}
\]

ISP-irreducible integrals $\rightarrow$ use IBPI to Master Integrals

5BOX

**Figure:** The three planar pentaboxes of the families $P_1$ (left), $P_2$ (middle) and $P_3$ (right) with one external massive leg.

**Figure:** The five non-planar families with one external massive leg.
Massive box as 3-fold Mellin-Barnes integral I

And finally we reproduce the box integral, dependent on $d$ and the internal variables $\{d, q_1, m_1^2, \ldots q_4, m_4^2\}$ or, equivalently, on a set of external variables, e.g. $\{d, \{p_i^2\}, \{m_i^2\}, s, t\}$:

$$J_4(d; \{p_i^2\}, s, t, \{m_i^2\}) = \left(\frac{-1}{4\pi i}\right)^4 \frac{1}{\Gamma\left(\frac{d-3}{2}\right)} \sum_{k_1, k_2, k_3, k_4 = 1}^4 D_{k_1 k_2 k_3 k_4} \left(\frac{1}{r_4} \frac{\partial r_4}{\partial m_{k_4}^2}\right) \left(\frac{1}{r_3} \frac{\partial r_3}{\partial m_{k_3}^2}\right) \left(\frac{1}{r_2} \frac{\partial r_2}{\partial m_{k_2}^2}\right) \left(\frac{1}{r_1} \frac{\partial r_1}{\partial m_{k_1}^2}\right) \left(m_{k_1}^2\right)^{d/2 - 1}$$

$$= \int_{-i\infty}^{+i\infty} dz_4 \int_{-i\infty}^{+i\infty} dz_3 \int_{-i\infty}^{+i\infty} dz_2 \left(\frac{m_{k_1}^2}{R_4}\right)^{z_4} \left(\frac{m_{k_2}^2}{R_3}\right)^{z_3} \left(\frac{m_{k_3}^2}{R_2}\right)^{z_2}$$

$$\Gamma(-z_4) \Gamma(z_4 + 1) \Gamma\left(z_4 + \frac{d-3}{2}\right) \Gamma\left(z_4 + \frac{d-1}{2}\right) \Gamma\left(z_3 + z_4 + \frac{d-2}{2}\right) \Gamma\left(z_3 + z_4 + \frac{d-1}{2}\right) \Gamma\left(z_2 + z_3 + z_4 + \frac{d-1}{2}\right) \Gamma\left(-z_2 - z_3 - z_4 - \frac{d+2}{2}\right) \Gamma(-z_2) \Gamma(z_2 + 1).$$

The representation (31) can be treated by the Mathematica packages MB and MBnumerics of the MBsuite, replacing AMBRE by a derivative of MBnumerics: MBOneLoop [22].
Progress in analytical/numerical approaches: Ben Page

Numerical Unitarity @ Two Loops [Abreu, Ita, Jaquier, Febres Cordero, BP ’17]

- Take an **ansatz** for loop-amplitude integrand, decomposing into master \((M_\Gamma)\) and surface \((S_\Gamma)\) integrands.

\[
\mathcal{A}(\ell, \bar{x}) = \sum_{\text{Topologies } \Gamma} \sum_{i \in M_\Gamma \cup S_\Gamma} \frac{c_{\Gamma,i}(\bar{x}) m_{\Gamma,i}(\ell)}{\prod_{\text{props } j} \rho_j}.
\]

[Ita ’15]

- **Numerically** fix \(c_{\Gamma,i}(\bar{x})\) on finite field* from on-shell data.

\[
\int = \sum_{\Gamma' \geq \Gamma, \atop i \in M_{\Gamma'} \cup S_{\Gamma'}} \frac{c_{\Gamma',i}(\bar{x}) m_{\Gamma',i}(\ell_{\Gamma'})}{\prod_{\text{props } j} \rho_j}.
\]

[BDDK ’94, ’95]

- Insert master integrals, expand \(\Rightarrow\) **integrated amplitude**.

- Amplitude naturally splits into **rational functions** of external kinematics \(c_{\Gamma,i}(\bar{x})\) and special functions (master integrals).

*See also [Peraro ’16]
Conclusions

- **Alternative** method for analytic computations: reconstruction from numerical samples over finite fields.

- We have **analytically computed** the leading-colour 5-gluon two-loop amplitudes.

- Natural next step - all 5-parton amplitudes at leading colour.

- **Interesting structures** revealed by computation.

The Challenges of Higher-Order Computations

Increasing the number of legs, loops and scales can greatly increase the complexity of a calculation in two key ways:

1) Expressions for the amplitudes (and/or IBP identities) can become large and computationally challenging to handle

→ Talk of Ben Page, Johann Usovitsch

2) The Feynman integrals encountered can become challenging to compute. They can have mathematical/algebraic structures beyond MPLs/GPLs (e.g. elliptic integrals)

→ Talk of Stefan Weinzierl

Proceeding purely analytically can become very challenging, numerical methods provide a complementary way to attack these problems

Standard Model Theory for the FCC-ee: The Tera-Z

Sep 6, 2018 - 243 pages

Conference: C18-01-12

Abstract (arXiv)
The future 100-km circular collider FCC at CERN is planned to operate in none of its modes as an electron-positron FCC-ee machine. We give an overview of the theoretical status compared to the experimental demands of one of the four foreseen FCC-ee operating stages, which is Z-boson resonance energy physics, FCC-ee Tera-Z stage for short. The FCC-ee Tera-Z will deliver the highest Integrated luminosities as well as very small systematic errors for a study the Standard Model (SM) with unprecedented precision. In fact, the FCC-ee Tera-Z will allow to study at least one more quantum field theoretical perturbative order compared to the LEP/SLC precision. The real problem is that the present precision of theoretical calculations of the various observables within the SM does not match that of the anticipated experimental measurements. The bottle-neck problems are specified. In particular, the issues of precise QED unfolding and of the correct calculation of SM pseudo-observables are critically reviewed. In an Executive Summary we specify which basic theoretical calculations are needed to meet the strong experimental expectations at the FCC-ee Tera-Z. Several methods, techniques and tools needed for higher order multi-loop calculations are presented. By inspection of the Z-boson partial and total decay widths analysis, arguments are given that at the beginning of operation of the FCC-ee Tera-Z, the theory predictions may be tuned to be precise enough not to limit the physics interpretation of the measurements. This statement is based on the anticipated progress in analytical and numerical calculations of multi-loop and multi-scale Feynman integrals and on the completion of two-loop electroweak radiative corrections to the SM pseudo-observables this year. However, the above statement is conditional as the theoretical issues demand a very dedicated and focused investment by the community.
