Overview

- 1 Introduction
- 2 Benchmark Selection
- 3 Monte Carlo
- 4 Event Reconstruction
- 5 Parton Level Results
- 6 Detector Level Results
- 7 Conclusion

Introduction

- Collider studies generally model Signal and Background separately.
- Define: $I = T - S - B$
- This assumption that interference is small may not hold for some areas of parameter space.

Signal to background interference in $pp \rightarrow tH^- \rightarrow tW^- b\bar{b}$ at the LHC Run-II

Abdesslam Arhrib¹, Rachid Benbrik^{2,3,4}, Stefano Moretti⁵, Rui Santos^{6,7,8} and Pankaj Sharma⁹

Figure: arxiv:1712.05018

- Interference can be of same order as signal, and sometimes negative.
- Interference large when width-mass ratio large.
- We look at $pp \rightarrow tbH^\pm \rightarrow tb\bar{t}\bar{b}$ in this study.

Current Exclusion

Process and Key Parameters

- Model: hMSSM
- Key Parameters:
 - $\tan \beta = 1.01$
 - $M_{H^\pm} \approx M_A \approx M_H \approx 635$ GeV
 - $\Gamma_{H^\pm} \approx \Gamma_A \approx \Gamma_H \approx 27$ GeV
- Process: $pp \rightarrow tbH^\pm \rightarrow tb\bar{t}\bar{b}$
- Model: $m_h^{\text{mod+}}$
- Key Parameters:
 - $\tan \beta = 3.42$
 - $M_{H^\pm} \approx M_A \approx M_H \approx 303.08$ GeV
 - $\Gamma_{H^\pm} \approx \Gamma_A \approx \Gamma_H \approx 0.93$ GeV
- Process: $pp \rightarrow tbH^\pm \rightarrow tb\bar{t}\bar{b}$

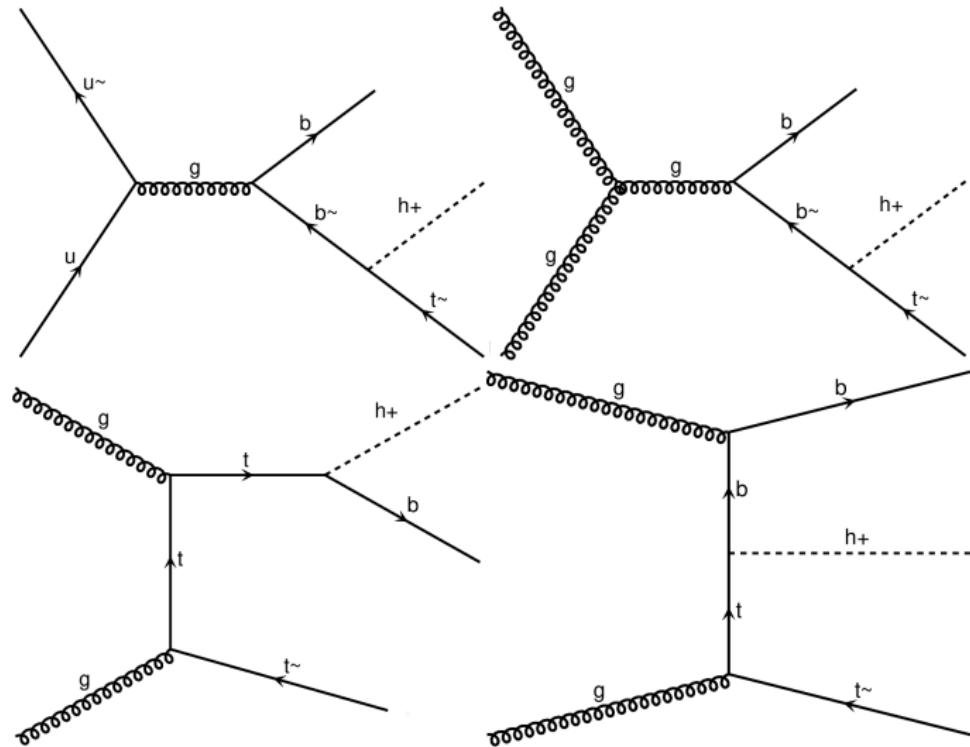

Figure: A selection of signal Feynman diagrams.

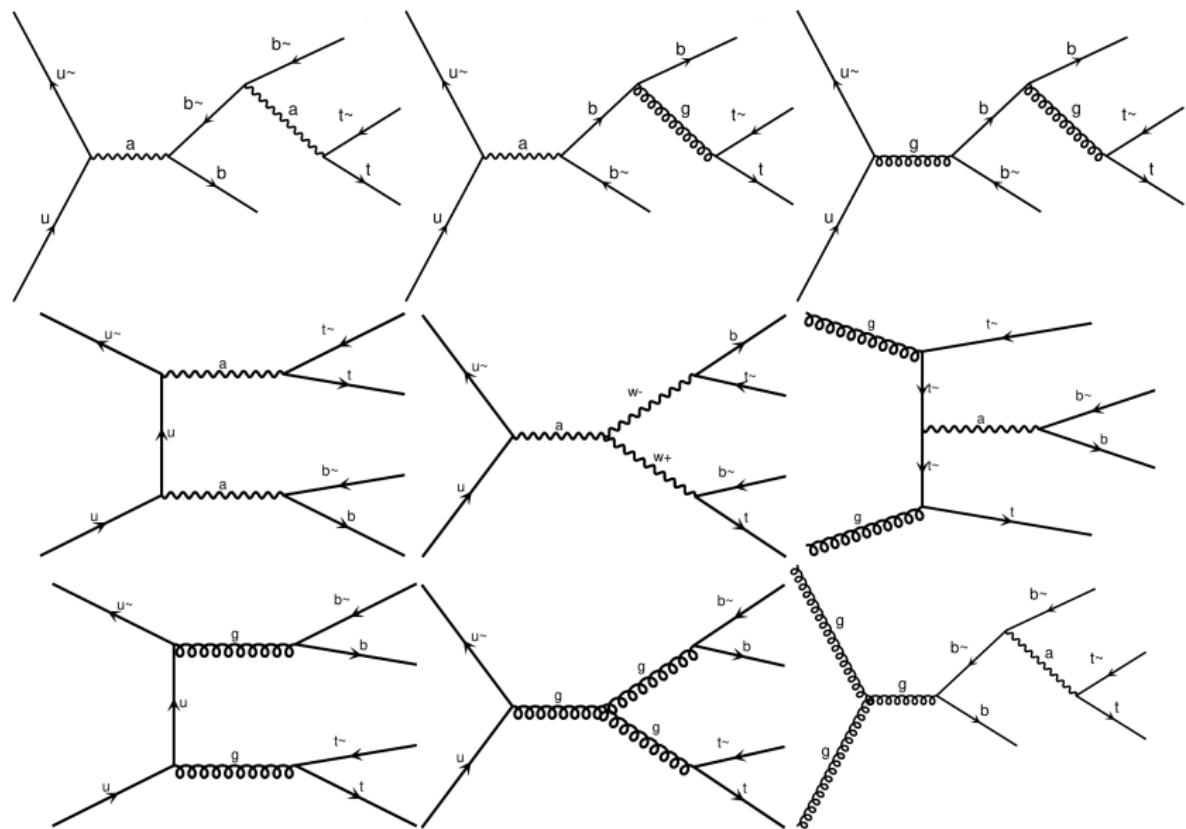

Figure: A selection of background Feynman diagrams.

Monte Carlo

- MadGraph5 used to generate 20,000,000 parton level events.
- PYTHIA8 used on 500,000 of these events for fragmentation/hadronization.
- Delphes used on (the same) 500,000 events for detector effects.
 - Standard ATLAS card used

Event Reconstruction

- The following vetoes are applied:
 - $N_\ell = 1$, $N_j \geq 5$, $N_b \geq 2$ or 3
- Longitudinal momentum of missing energy solved using:

$$p_\nu^z = \frac{1}{2p_{\ell T}^2} \left(A_W p_\ell^z \pm E_\ell \sqrt{A_W^2 \pm 4p_{\ell T}^2 E_{\nu T}^2} \right)$$

where, $A_W = M_{W^\pm}^2 + 2p_{\ell T} \cdot E_{\nu T}$

- Reconstruction performed via simultaneous minimization of:

$$\begin{aligned} \chi_{\text{had}}^2 = & \frac{(M_{\ell\nu} - M_W)^2}{\Gamma_W^2} + \frac{(M_{jj} - M_W)^2}{\Gamma_W^2} + \frac{(M_{\ell\nu j} - M_T)^2}{\Gamma_T^2} \\ & + \frac{(M_{jjj} - M_T)^2}{\Gamma_T^2} + \frac{(M_{jjjj} - M_{H^\pm})^2}{\Gamma_{H^\pm}^2} \end{aligned}$$

- and the equivalent term for a leptonically decaying H^\pm .

Event Reconstruction

Table: Cut flow results presented in expected event yield with 3000fb^{-1} of luminosity for the $m_h^{\text{mod+}}$ benchmark.

Interference Shape

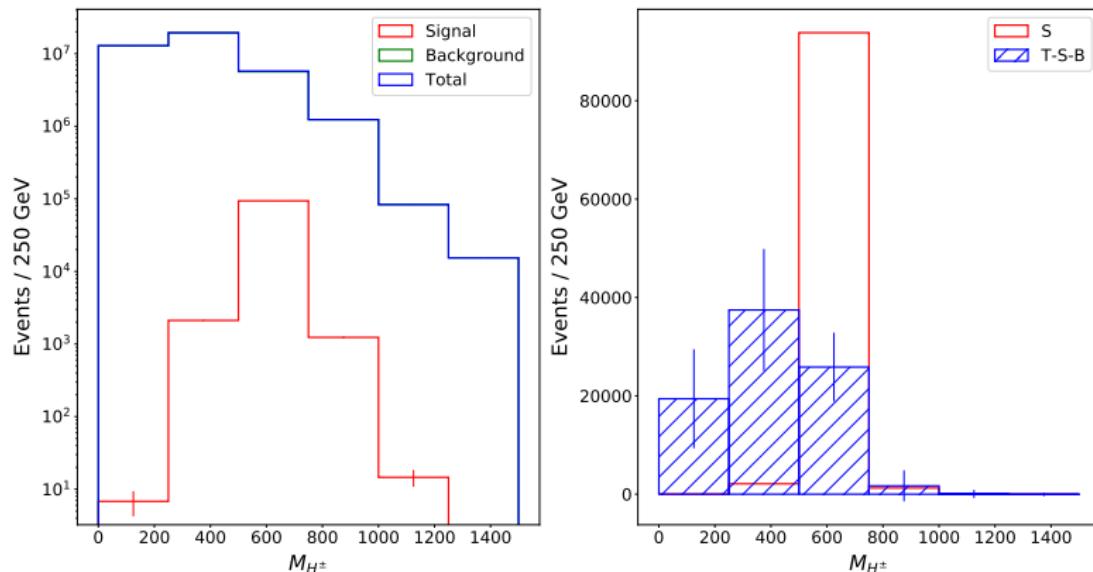

Figure: The charged Higgs invariant mass distribution of the signal, background as well as total (left) plus the interference and signal (right) at parton level and without cuts in the hMSSM scenario.

Interference Shape

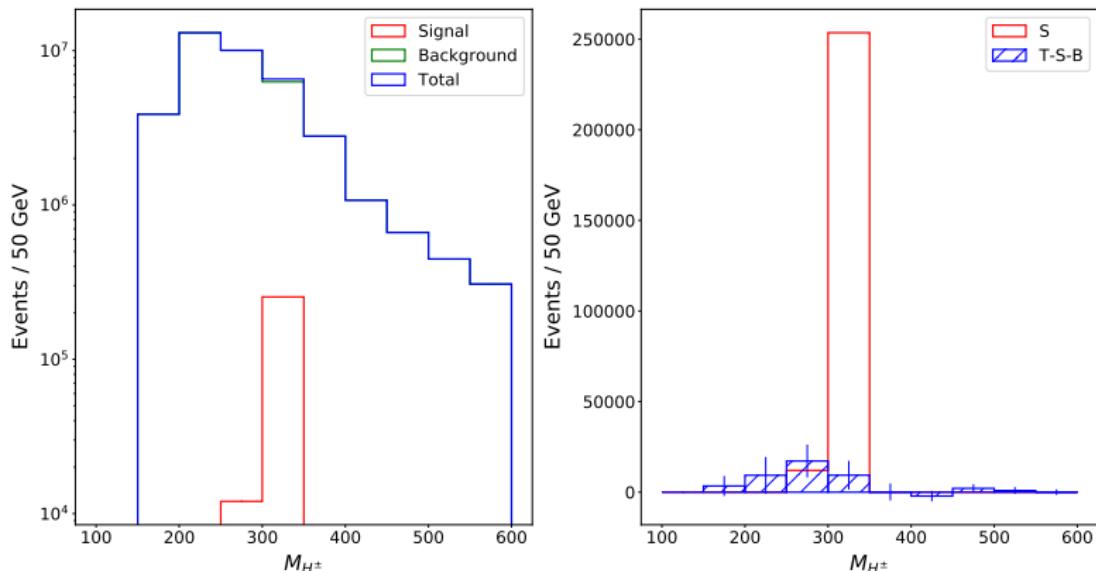

Figure: The charged Higgs invariant mass distribution of the signal, background as well as total (left) plus the interference and signal (right) at parton level and without cuts in the $m_h^{\text{mod+}}$ scenario.

Summary and Conclusion

- Interference effects non-negligible in some high width-mass ratio scenarios.
- To account for this we must model Signal, Background and Signal+Background separately.
- hMSSM presents significant interference in reasonable circumstance with high width-mass ratio.
- $m_h^{\text{mod}+}$ presents significant interference behaviour during cuts in low width-mass ratio.
- Parton and Detector level results of inclusive cross section presented.
- Results on detector level interference shapes presented.
- How does one design a machine learning framework that includes interference effects?
- How does interference effect the machine learning discriminant?
