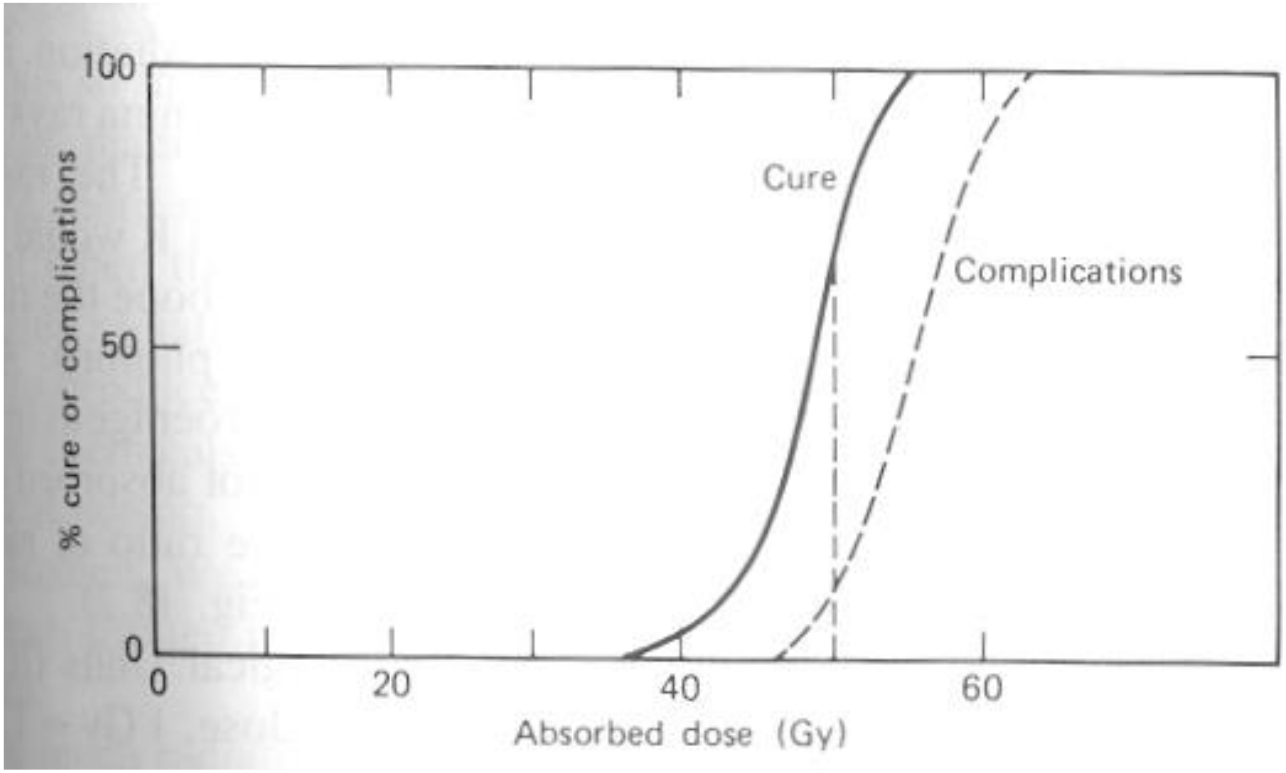
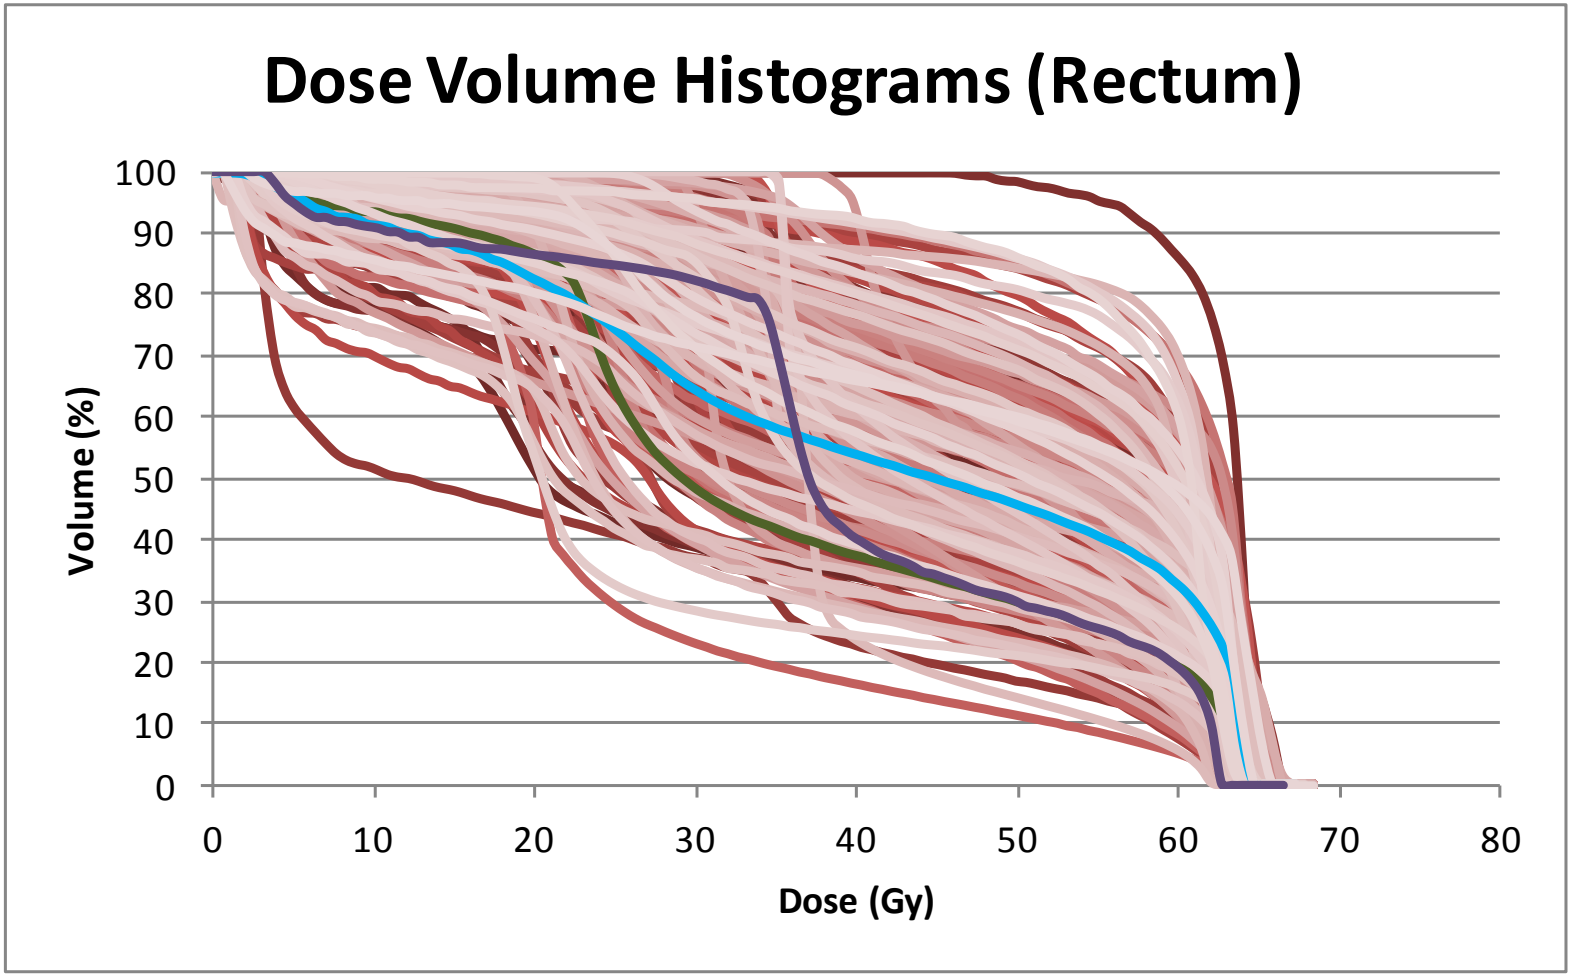
Where do we start?



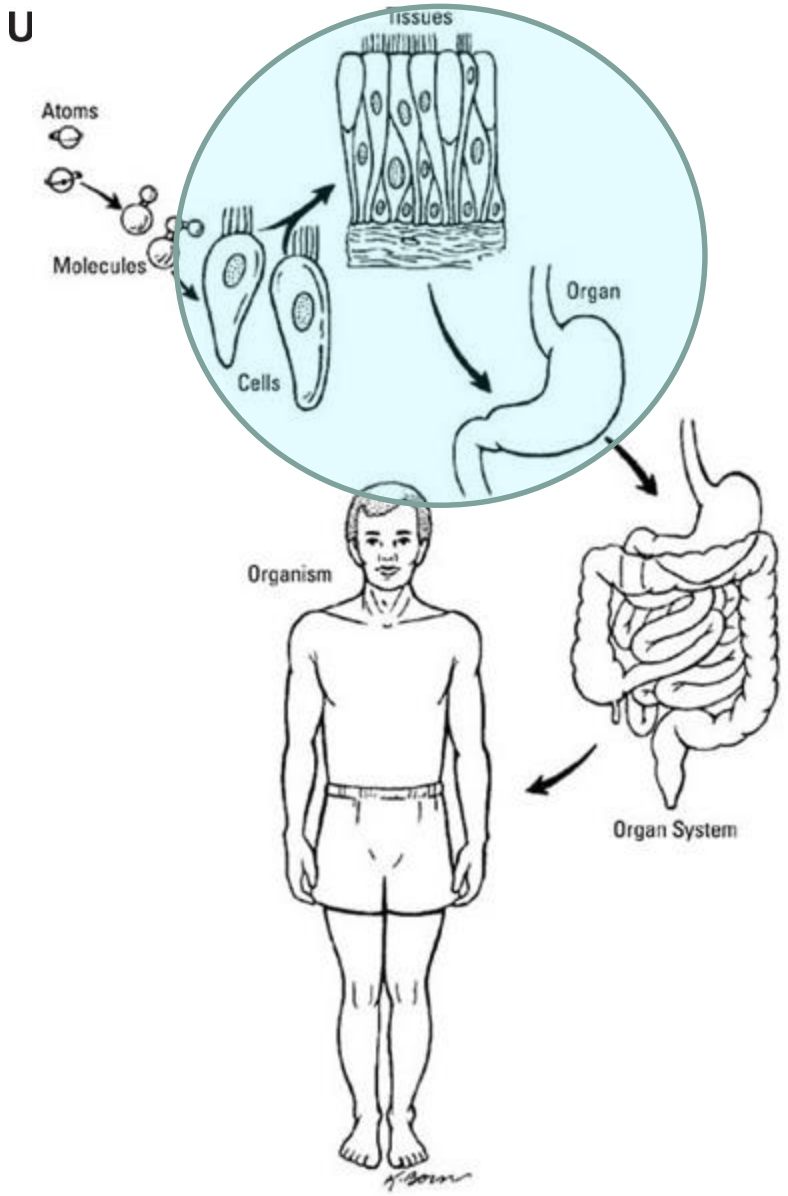
- We want to characterise the response of normal tissues so that we can design treatments that minimise the risk of toxicity and maximise the probability of “cure”

Inhomogeneity of dose distribution



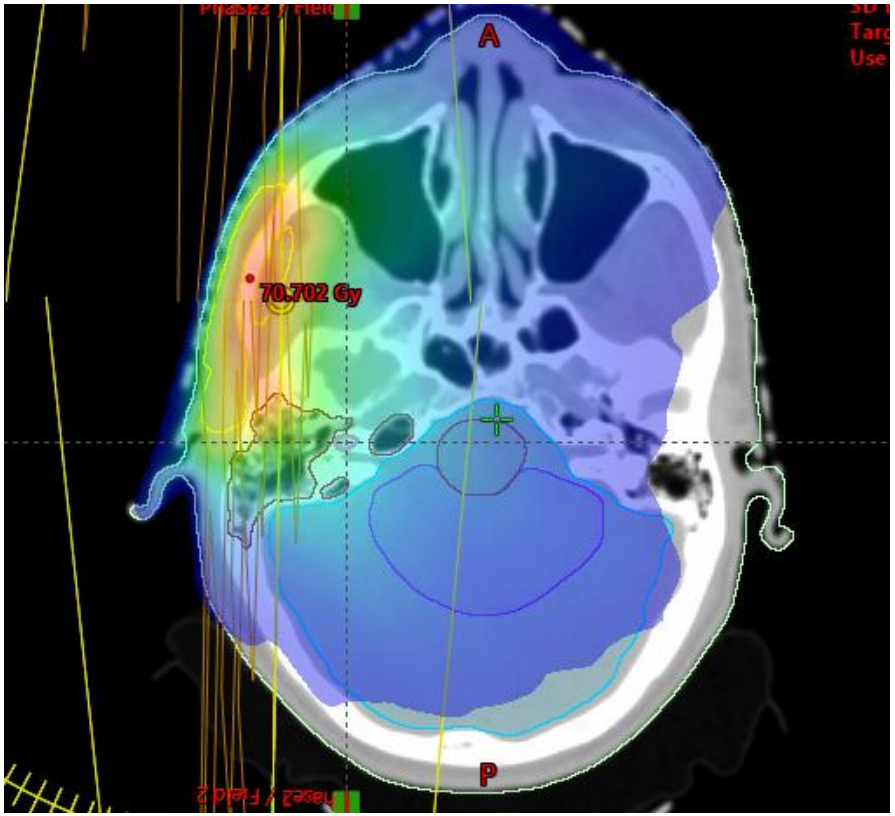
Normal tissue toxicity

- Cells
- Tissues
- Organs



http://www.dummies.com/how-to/content/building-the-body-from-atoms-to-organs.html

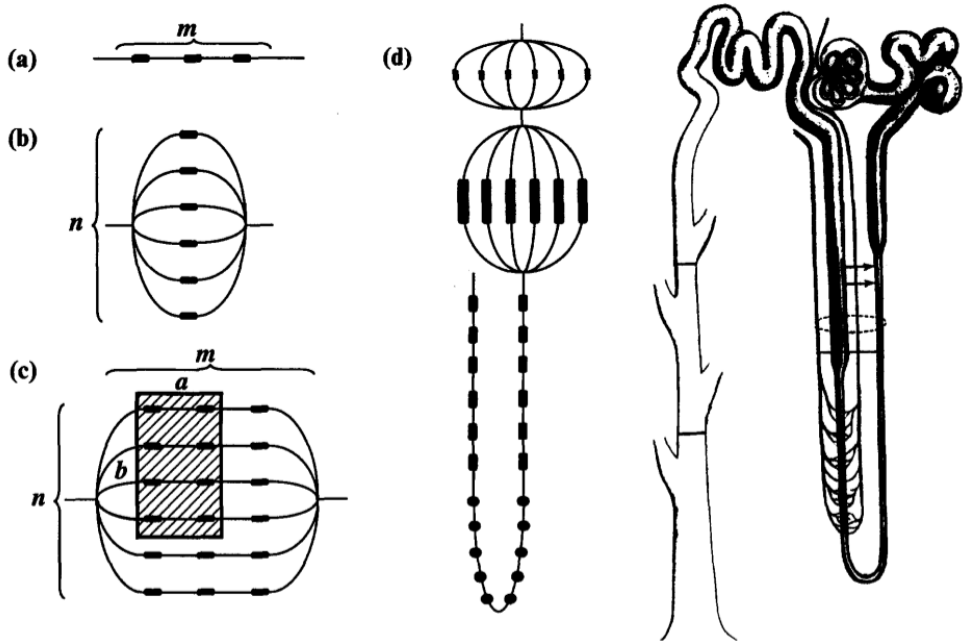
Plan Comparison



Organ architecture

- Each organ different in terms of FSU interaction
- Parallel type response like a rope: it can perform its function even if some strands break.

- **Large volume effect**
- **Serial type response like a chain: function is lost if any one link breaks.**
  - **Small volume effect**

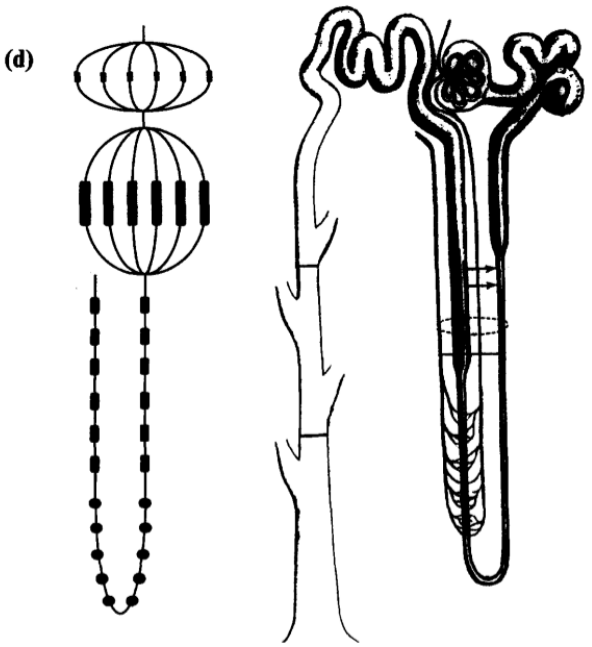


Källman, P.; Ågren, A. & Brahme, A. Tumour and normal tissue responses to fractionated non-uniform dose delivery. Int J Radiat Biol, 1992, 62, 249-262

Organ architecture

In some tissues FSU are anatomically defined structures

"An example of the parallel-serial model applied to a functional subunit of kidney, a nephron, is shown in d). The first parallel structure is the capillary system inside the glomerular capsule, followed by the capsule itself and the limbs and Henle's loop.



In other tissues there is no anatomical demarcation of the FSU

Skin
Mucosa
Spinal cord

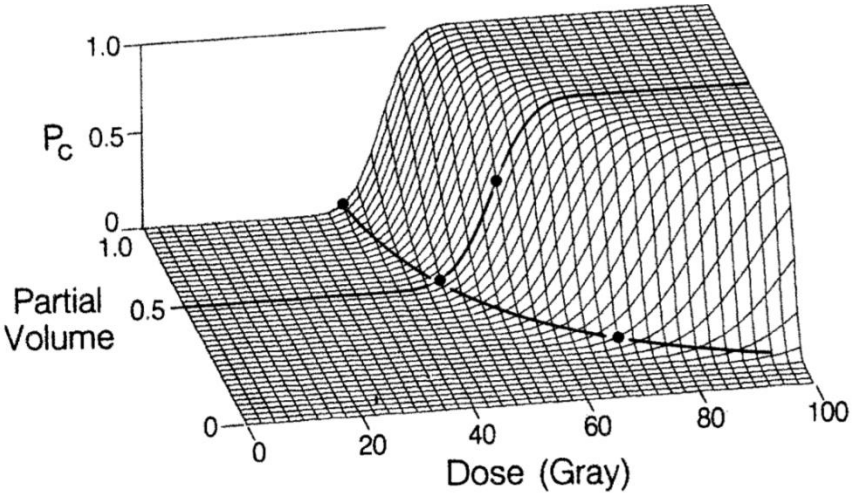
Källman, P.; Ågren, A. & Brahme, A. Tumour and normal tissue responses to fractionated non-uniform dose delivery. Int J Radiat Biol, 1992, 62, 249-262

Volume effect

Sigmoid dose-response for partial (uniform) organ irradiation:

The volume effect depends on:

- **Functional reserve**
- **Migration of cells**
- **Stochastic tissue damage**
- **Inflammatory response?**



Nb volume effect ≠ FSU in planning terms

Each with 10 sections

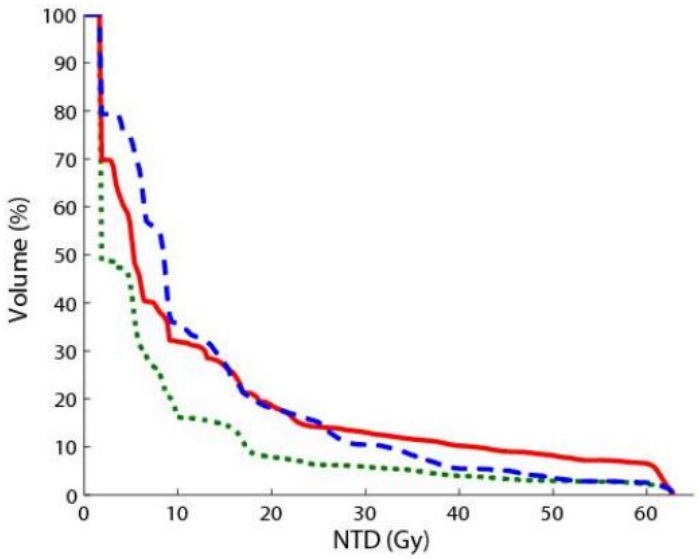
1. **Clinical Significance**- Describes the clinical situations where the organ is irradiated, and the incidence/significance of organ injury.
2. **Endpoints**- Describes the different endpoints often considered when assessing injury, the impact of endpoint-selection on **the reported injury rates, the challenges/utilities of different endpoints, and the time course of organ injury.**
3. **Challenges Defining Volumes**- **Describes how the organ is typically defined (or segmented)** on treatment planning images. Includes a discussion of uncertainties/challenges in organ definition (e.g. changes in organ volume/shape during therapy), and the associated impact on DVH's and dose/volume/outcome analyses.
4. **Review of Dose/Volume Data**- A comprehensive summary of reported 3D dose/volume data for clinically-relevant outcomes.
5. **Factors Affecting Risk**- Other clinical factors affecting the risk of injury are noted (e.g. age, combined modality therapy, dose fractionation).
6. **Mathematical/Biological Models**- Models that have been used to relate 3D dose/volume data to clinical outcomes are summarized, along with associated model parameters, limitations and uncertainties.
7. **Special Situations**- Most of the data discussed relates to conventional fractionation. This section describes situations were the presented data/models may not apply (e.g. hypo-fractionation).
8. **Recommended Dose/Volume Limits**- The available information is condensed into meaningful dose/volume limits, with associated risk rates, to apply clinically.
9. **Future Toxicity Studies**- Describes areas in need of future study.
10. **Toxicity Scoring**- Recommendations on how to score organ injury.

Common dose parameters

- Lots of data on normal tissue response have been collected over the last 20 years.
- Different dose parameters correlate with toxicity
  - Maximum dose
  - Mean dose
  - V_x (the volume receiving at least x Gy)
- The relevant dose depends on the organ architecture, the size of the functional reserve.
- No reserve: maximum dose?
- Large reserve: V_x or mean dose?

Dose volume histogram (DVH)

- (Cumulative) dose volume histograms (DVHs) are often used to evaluate treatment plans.
- Useful for comparing alternative plans
- If two DVHs overlap it is not clear which is better.
- DVH needs to be reduced to a single parameter.



Regression-based NTCP models

- NTCP=$\frac{1}{1+e^{-(\beta_0+x_1\beta_1\ldots\ldots)}}$
- Model with a continuous output between 0 & 1.
- Coefficients fitted with multivariate logistic regression

Brain stem

Oral cavity

Parotid gland

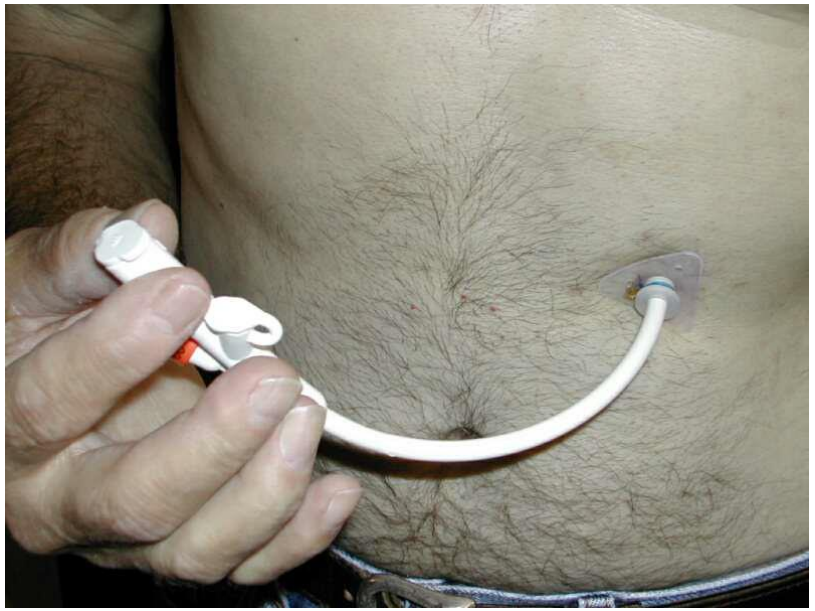
Primary planning target volume

Nodal planning target volume

Clinical problem

- Oral mucositis
- Dysphagia
- Severe impact on quality of life
- Acute and often transient
- Consequential late effects

- Limits dose-escalation and accelerated fractionation



Patients

PARSPORT	71	Oropharynx, hypopharynx	Bilateral; Conventional, IMRT	No
COSTAR	78	Parotid gland	Unilateral; Conventional, IMRT	No
Dose Escalation	30	Hypopharynx, larynx	Bilateral; IMRT	Yes
Midline	117	Oropharynx	Bilateral; IMRT	Yes
Nasopharynx	36	Nasopharynx	Bilateral; IMRT	Yes
Unknown Primary	19	Unknown primary	Bilateral; IMRT	Yes

Toxicity scoring

Clinical oral mucositis	Erythema of the mucosa	Patchy ulcerations	Confluent ulcerations	Tissue necrosis; significant spontaneous bleeding
Dysphagia	Symptomatic, able to eat regular diet	Symptomatic and altered eating/swallowing; IV fluids indicated < 24 hours	IV fluids, tube feedings, or TPN indicated >= 24 hours	Life threatening consequences

- **Prospectively measured at baseline, weekly during and 1, 2, 3, 4 and 8 weeks post-radiotherapy**
- **Patients with missing data excluded**
- **Peak grade < 3 vs >= 3**

Clinical data

- Age
- Sex
- Primary disease site
- Definitive radiotherapy vs postoperative radiotherapy
- Concomitant treatments
- Induction chemotherapy
- Concurrent chemotherapy regime

- No smoking, alcohol or genetic data

Conclusions

University College London Hospitals
NHS Foundation Trust

- Trained and validated predictive model of swallowing dysfunction
- High performance model for severe dysphagia
- - No concurrent chemotherapy has highest absolute regression coefficient
- - V70 has highest regression coefficient out of dose-volume features

uclh

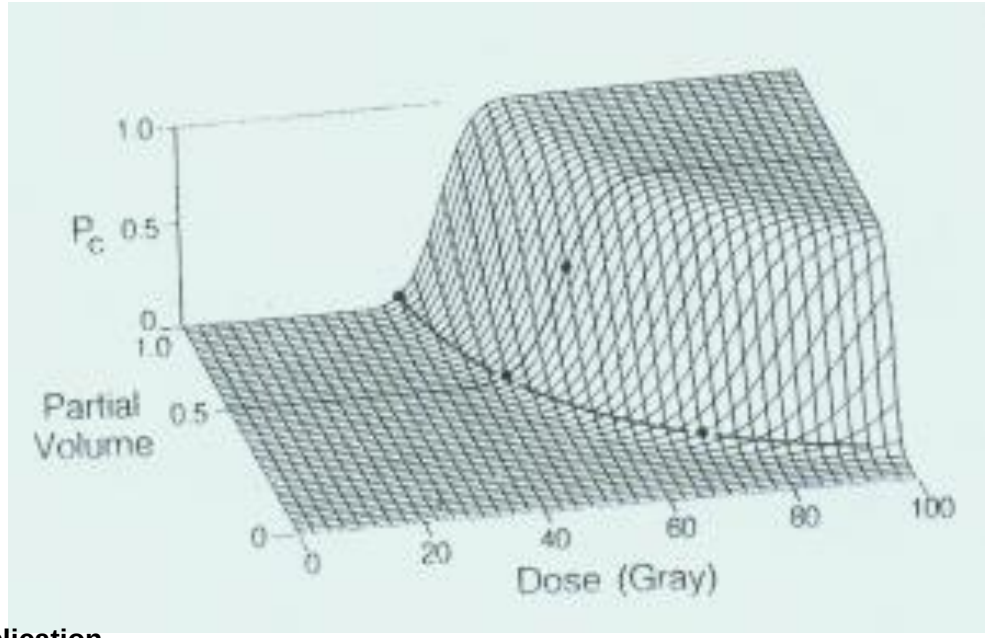
Lyman Model 1985

$$NTCP = \frac{1}{\sqrt{2\Pi}} \int_{-\infty}^{t} e^{-t^2/2}\, dt$$

where

$$t = \frac{D - TD_{50}(v)}{m * TD_{50}(v)}$$

$$TD_{50}(v) = TD_{50}(1) / V^{n}$$

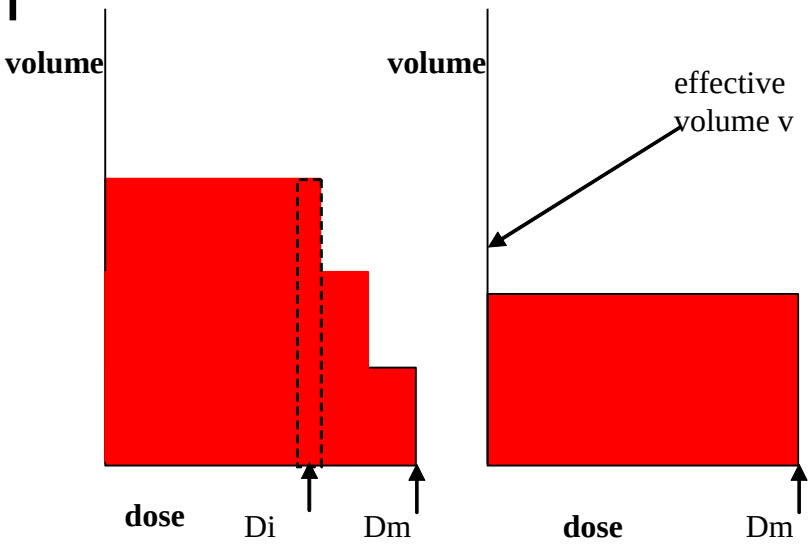


D **maximum dose to the structure**
TD**50(1) tolerance dose for 50% incidence of complication**
m **slope of TD50(1)**
n **indicates serial/parallel nature of the structure**
v **effective volume if the structure was irradiated uniformly to D**

Lyman,J.T. Complication probability as assessed from dose-volume histograms. ***Radiat. Res. Suppl*** **8, S13-S19 (1985).**

- Dose Volume Histogram Reduction

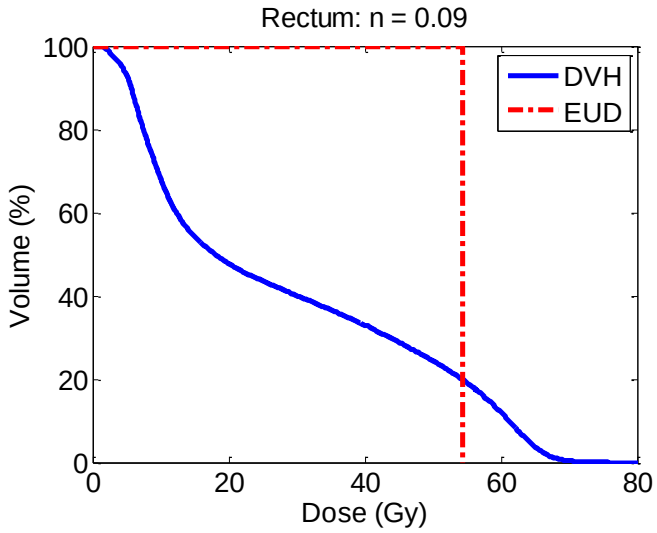
$$v = \Sigma\left(Di/Dm\right)^{1/n} \Delta v_i$$

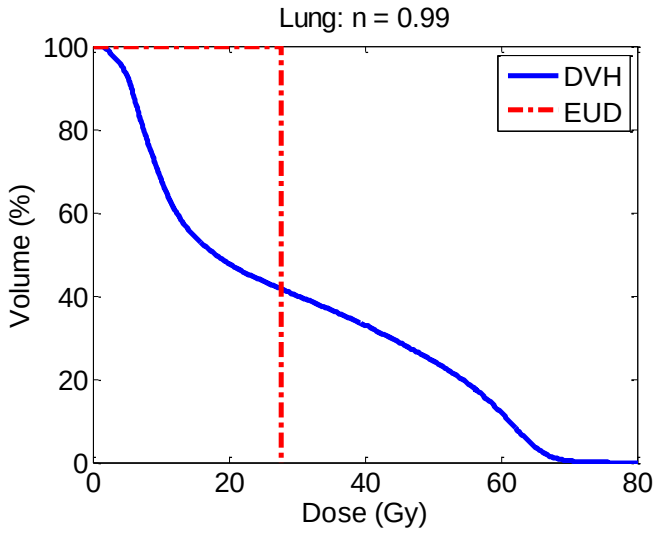


Kutcher,G.J.et al, Histogram reduction method for calculating complication probabilities for three-dimensional treatment planning evaluations. *Int. J. Radiat. Oncol. Biol. Phys.* 21, 137-146 (1991).

Equivalent uniform dose

$$EUD = \sum_i \left(D_i^{\frac{1}{n}} \frac{V_i}{V_{tot}} \right)^n$$





Parameter '*n*' is organ (endpoint) specific

- **Low (≈ 0): small volume effect, EUD ≈ max dose**
- **High (= 1): large volume effect, EUD = mean dose**

uclh

Maximum Likelihood Estimation

$$\mathrm{LLH}(\mathrm{TD50}(1), m, n) = \sum_{y(i)=1} \ln(\mathrm{NTCP}(\mathrm{TD50}(1), m, n)) + \sum_{y(i)=0} \ln(1 - \mathrm{NTCP}(\mathrm{TD50}(1), m, n))$$

- **y(i) known outcome**

Bootstrapping

- **Sample available data (with replacement) to create different populations**
- **Test generalisability of fit.**
- **Results shown for 1000 Bootstrapped cohorts**

Fitting NTCP models :an example

- RT01 Prostate Radiotherapy Trial
  Patients randomised to 64 Gy vs 74 Gy
- Accrual from Jan 1998 to Dec 2001
- Patients randomised from 23 centres throughout the UK, 1 in NZ, 1 in Victoria

Fitting NTCP models :an example

- Rectal Bleeding -RMH
- Proctitis-RTOG
- Stool Frequency- Lent Som
- Loose Stools -UCLA QoL
- Rectal Urgency -UCLA QoL

0=none 1=mild 2=moderate/severe toxicity

1000 Bootstrapped cohorts fitted using maximum likelihood estimation.

Bootstrap Approach

Endpoint (toxicity grades)	TD50(1) (Gy)	SD	m	SD	n	SD

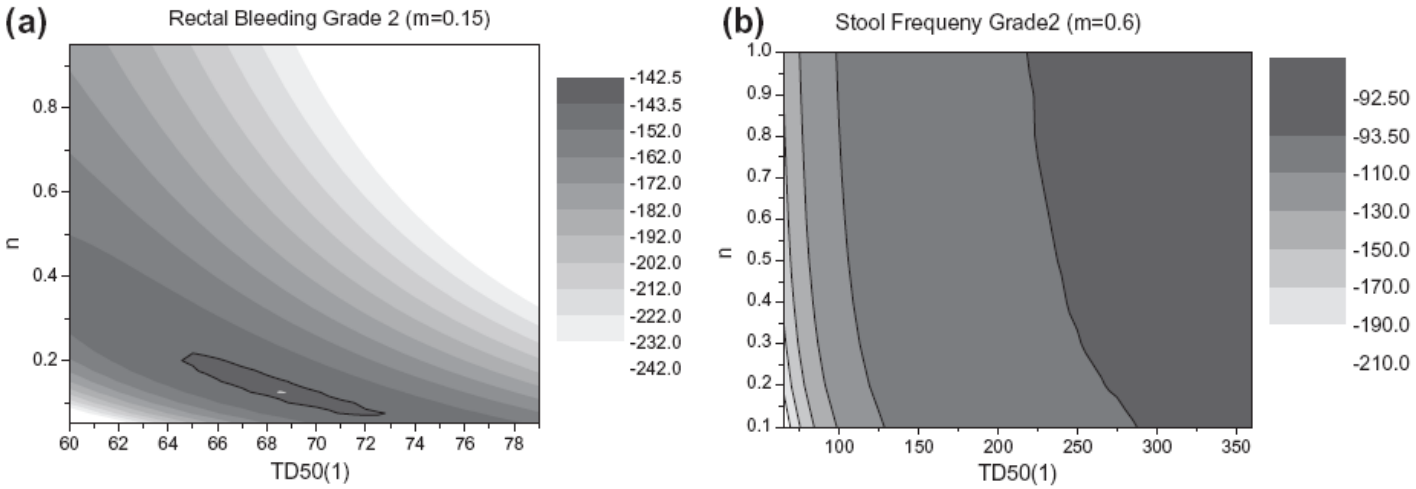
Quantec Values Grade 2 Toxicity

TD50 76.9Gy n=0.09 m=0.13

Maximum Likelihood Estimation
Log-likelihood values



Taking empirical models further

- Accounting for confounding factors
  - Confounding factors include any non-dosimetric factors (*X*) influencing the outcome, as these are not modelled.
  - Health status, chemo/surgery, radiosensitivity etc.
  - Sharper slope, greater certainty

$$\mathrm{NTCP} = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{t} e^{-x/2} \mathrm{d}x$$

$$t = \frac{\varphi - \varphi_{50}}{m \cdot \varphi_{50}} + \beta_2 X_2 + \cdots + \beta_n X_n$$

The Critical Volume

In the Critical Volume model the summary measure is a damaged volume, calculated using a local dose-effect function $E(D_i)$.

$$\text{Damaged volume} = \sum_i E(D_i)\frac{V_i}{V_{tot}}$$

Di **= total dose to bin *i***
Vi **= absolute volume in bin *i***
Vtot **= total organ volume**

D50 **= dose causing 50% local effect**
k **= parameter for slope of curve**

$$E(D_i) = \frac{1}{1 + (D_{50}/D_i)^k}$$

Function 1:
2 parameters

$$E(D_i) = \begin{cases} \dfrac{D_i/D_{50} - 1}{1 + (D_i/D_{50} - 1)^2} + {}^1\!/_2 & \text{when } D_i < 2D_{50} \\ 1 \text{ when } D_i \geq 2D_{50} \end{cases}$$

Function 2:
1 parameter

$$E(D_i) = \begin{cases} 0 \text{ when } D_i < D_{50} \\ 1 \text{ when } D_i \geq D_{50} \end{cases}$$

Function 3:
1 parameter

The Relative Seriality model

The Relative Seriality model first calculates a probability of local damage for each dose bin in the DVH:

$$P(D_i) = 2^{-\exp\left(e\gamma\left(1-\frac{D_i}{D_{50}}\right)\right)}$$

Di **= total dose to bin *i***
D50 **= Dose causing 50% probability**
γ **= slope of the curve**

Then NTCP is estimated using the relative seriality parameter '*s*'.

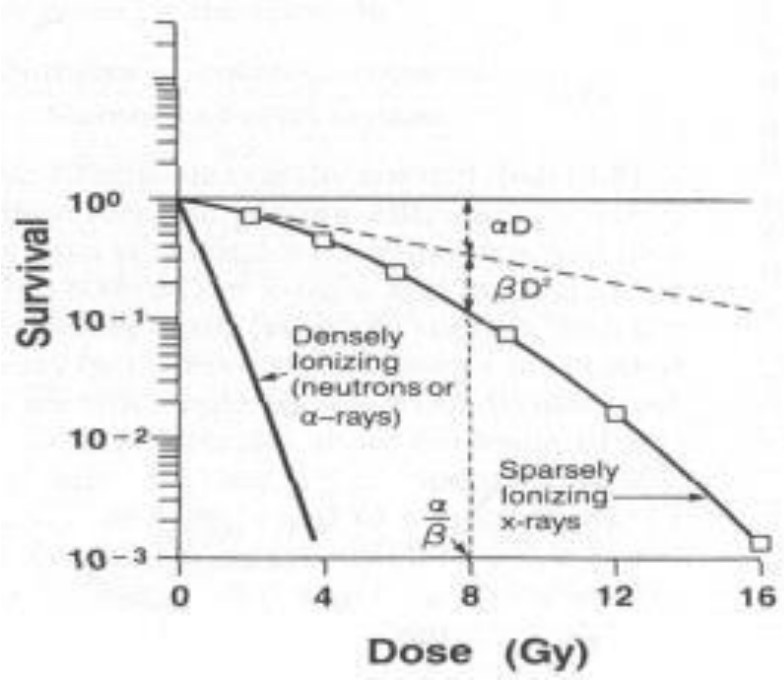
- **Serial organs: *s* = 1, high doses to small volume important**
- **Parallel organs: *s* ≈ 0, large irradiated volume important**

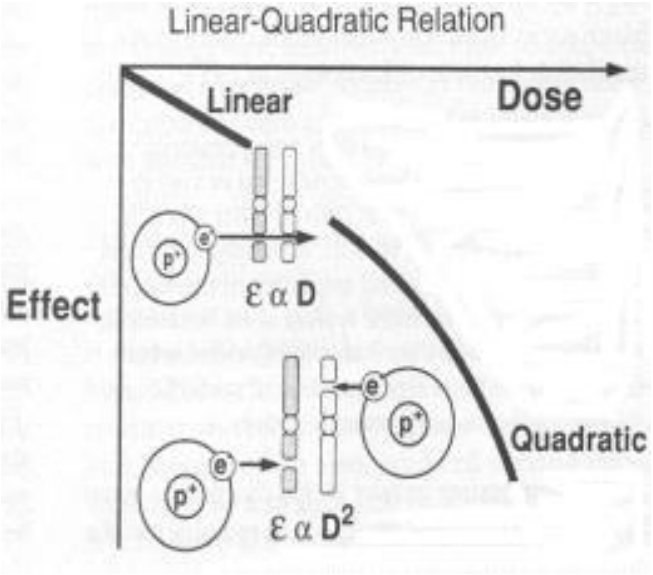
$$\mathrm{NTCP} = \left(1 - \prod_i (1 - P(D_i)^s)^{\frac{V_i}{V_{tot}}}\right)^{1/s}$$

Vi **= absolute volume in bin *i***
Vtot **= total organ volume**
s **= relative seriatlity parameter**

uclh

Fractionation
Linear Quadratic (LQ) Model





$S \sim \exp(-\alpha D - \beta D^2)$

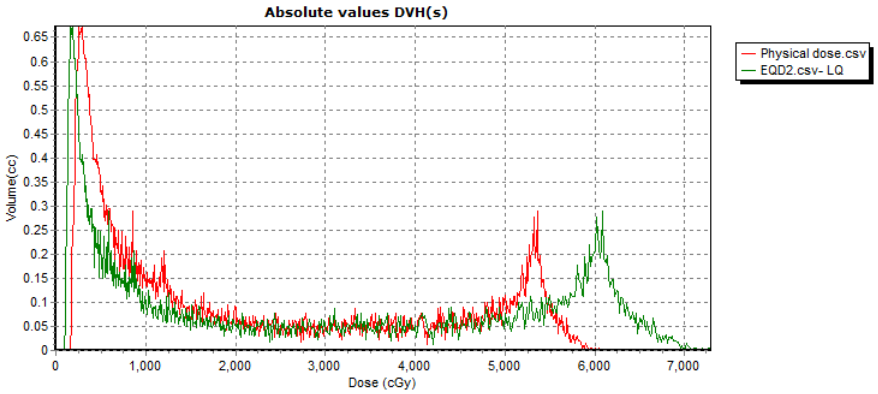
Acute responding tissues α/β~10 late responding tissues α/β~3 (classically)

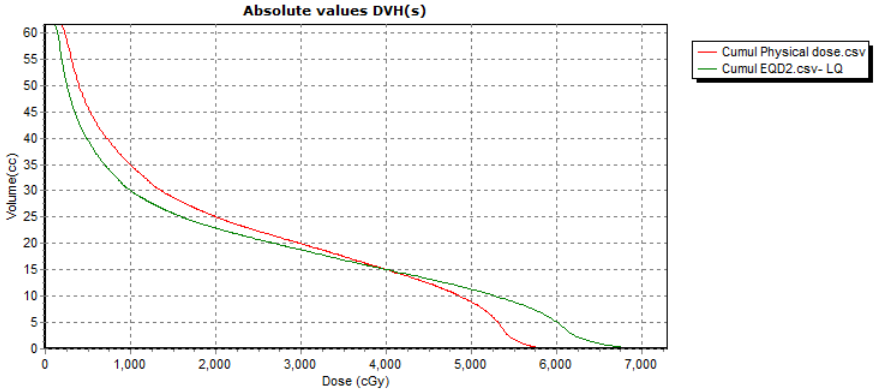
Illustration from *Hall E & Giaccia A. Radiobiology for the Radiologist (Lippincott-Williams Wilkins 2012).*

Fractionation correction!

Each bin in the DVH receives a different dose per fraction.

- Convert each dose-bin to 2Gy fraction equivalence (reference conditions).





$$BED = D\left[1 + {d}/{(\alpha/\beta)}\right]$$

$$D_i^{2Gy} = D_i\left[\frac{d + (\alpha/\beta)}{2 + (\alpha/\beta)}\right]$$

uclh

Example

DVHs for 2 lung cancer patients

- **Total lung – GTV**
- **Fractionation correction (α/β = 3 Gy)**
- **NTCP estimated using 3 different models**
- **Parameter values from Seppenwoolde et al. 2003**

	Patient 1	Patient 2
LKB	9.2%	5.4%
Critical Volume	9.9%	6.9%
Relative Seriality	8.5%	4.4%

When can I use NTCP?

- ICRU report 83: level 3 dose reporting
- Ranking treatment plans
- Evaluation of treatment data from clinical studies; derive parameter values locally
  - Better to used locally derived parameter values than published values
- Develop new potential techniques
- Dose prescription
- Radiobiological plan optimisation

Which model should I use?

- Preferably several
- The LKB model is the most commonly used model and has parameter values published for many organs/endpoints (e.g. QUANTEC).
- All the above models are empirical.
  - Statistical fits to clinical data
  - Biological interpretation of DVH reduction method should not be relied on blindly.
- The more parameters the more clinical data needed for parameter fitting. Up to 3 parameters often appropriate.
- Datasets often in the order of 100-300 patients. The more ‘events’, the more information to model on.

Important considerations

- The model is only as good as the data used for parameter fitting.
  - Well-designed study (unbiased, representative)?
  - Sample size, number of events
  - Uncertainties in dose distributions (incl. outlining, organ motion, organ definition)

Important considerations

- The model is only reliable for plans reasonably similar to the plans included in the study (also applies to patient specific factors).
- When a model is used without knowledge of these factors, or for a different technique/patient group, the same limitations apply as to empirical ‘tolerance doses’.
- NTCP is continuous but the patient outcome is binary

Patient Selection

- Step 1 NTCP Models
  - Data from optimal photon treatment
- Step 2 In silico planning studies
  - Photon vs Proton
- Step 3 Estimation of clinical benefit

Step 3 Estimation of clinical benefit

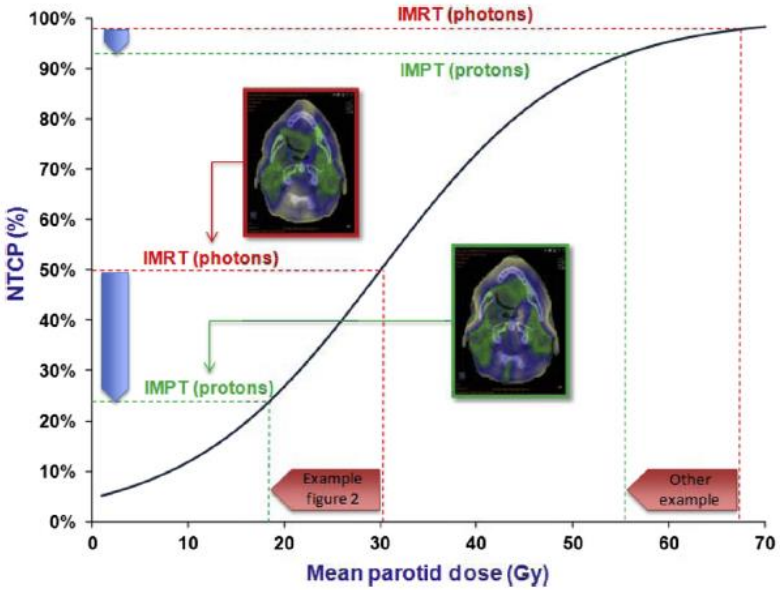

Fig. 3. Translation of the results of the individual ISPC-study depicted in Fig. 2 with regard to xerostomia. The reduction of the mean parotid dose from 30.1 Gy to 18.4 Gy (red arrow: example Fig. 2) corresponds with an estimated NTCP-value reduction for severe xerostomia from 50% to 24% according to the NTCP-model published by Semenenko. However, exactly similar absolute dose reductions (red arrow: other example) result in a minimal estimated NTCP-value reduction when the initial dose is much higher, due to the shape of the NTCP-curve.

Estimation of clinical benefit

Final Comments

Need to be cautious when applying constraints or predictive model derived from one technique to patients treated with a different technique.

Know the limitations of the model and accept that data doesn't always fit the model

Consider the definition of toxicity used to derive the model and what is relevant to the clinic.

All constraints and models should be independently validated.
