Ultra-peripheral heavy-ion collisions + forward/diffraction at RHIC

Wednesday, 31 July 2019 16:00 (20 minutes)

In recent years the STAR Collaboration collected a large sample of ultra-peripheral heavy-ion collisions. The photoproduction of J/Psi vector mesons is sensitive to the gluon content of the target nucleon or nucleus. We will present results from a statistically large sample of J/Psi production in Au+Au collisions. A significant result comes from the study of the p_T distributions, which clearly show two components, from scattering off the entire Au nucleus or off individual nucleons inside the nucleus. From a smaller sample of J/Psi production in p+Au collisions, with polarized protons, we will discuss the status of a first study of the asymmetry of J/Psi production. A non-zero asymmetry would be the first measure of the generalized parton distribution, E , for gluons, which is connected with the orbital angular momentum of partons in the nucleon. The present study is a proof-of-principle, and we will discuss the possibilities with larger data samples from future polarized p+p and p+Au RHIC runs.

In recent years, STAR has also accumulated data in polarized p+p collisions with a Roman Pot system which measures forward-scattered protons. We will present results on elastic p+p scattering, including the elastic and total cross sections and the $|t|$ distribution. Results from low mass particle/antiparticle pairs from central exclusive production will also be discussed, along with charged particle spectra in single diffractive dissociation.
