Universität Hamburg

RADCOR 2019  
September 9-13, Avignon, France

# Motivation: NNLO time-like splitting functions

Time-like splitting functions:

- Scale evolution kernels for **parton fragmentation distributions**.
- **Mostly** known at NNLO. [Mitov, Moch, Vogt '06; Moch, Vogt '07; Almasy, Moch, Vogt '11]
- A leading color limit known at N<sup>3</sup>LO. [Moch, Ruijl, Ueda, Vermaseren, Vogt '17; '18]

NNLO corrections:

- Calculated via an **analytic continuation** from the **space-like** case.
- An inherent uncertainty in the analytic continuation leaves **one of the terms** in  $P_{qg}^{(2)T}$  and  $P_{gq}^{(2)T}$  **undetermined**.
- To fix the missing terms, a **direct calculation** is required.

# Calculating time-like splitting functions

“Direct” calculation:

[Gutliar, Moch '15]

- Analytically calculate the differential cross-section of

$$e^+e^- \rightarrow \gamma^* \rightarrow \text{parton } p + \dots,$$

in the energy fraction of one of the outgoing partons,

$$x = 2q \cdot k_p / q^2.$$

- Read off the splitting functions from the poles of this cross-section:

$$\frac{d\sigma_p}{dx} \sim \dots + \left(\frac{\alpha_s}{2\pi}\right)^1 \left\{ \dots - \frac{1}{\epsilon} P_{pq}^{(0)T} \right\} + \left(\frac{\alpha_s}{2\pi}\right)^2 \left\{ \dots - \frac{1}{2\epsilon} P_{pq}^{(1)T} \right\} + \left(\frac{\alpha_s}{2\pi}\right)^3 \left\{ \dots - \frac{1}{3\epsilon} P_{pq}^{(2)T} \right\}.$$

- The needed  $P_{gq}^{(2)T}$  shows up at  $\alpha_s^3$  (N<sup>3</sup>LO) of  $d\sigma_g/dx$ !
- To obtain  $P_{qg}^{(2)T}$  do the same, but use a Higgs instead of  $\gamma^*$ .

# Calculating the differential cross-section

Master integrals for  $d\sigma/dx$  at N<sup>3</sup>LO are **not all known!**

- They can be calculated via **differential equations** (in  $x$ ).
  - Partially done.  $\mathcal{O}(500)$  of master integrals expected in total.
  - An  **$\epsilon$ -form** can be found for most of the differential equations; automatized via **Fuchsia**. [Gitusliar, V.M. '17]
  - Solvable in multiple polylogarithms, with poles at  $\{-1, 0, 1, 2\}$ .
- How to fix the **integration constants**?
  - An integral over all  $x$  values should turn a differential cross-section into a **fully inclusive one**,  $\int dx \frac{d\sigma}{dx} = \sigma$ . Apply for each master separately!
  - Master integrals for fully inclusive cross-sections at N<sup>3</sup>LO are needed.

In short:

- Eventual goal: NNLO corrections to time-like splitting functions.
- Current goal: master integrals for **fully inclusive cross-sections at N<sup>3</sup>LO**.

# Inclusive cross-section master integrals

For a fully **inclusive decay cross-section** of an off-shell particle:

$$\sigma \sim \sum_n \int dPS_n |\langle p_1, \dots, p_n | S | q \rangle|^2 = \sum_n \int dPS_n \left| \text{diagram}_1 + \text{diagram}_2 + \dots \right|^2$$

Expanding the module squared, each term becomes a **cut propagator**:

$$\int dPS_3 \left( \text{diagram}_1 + \text{diagram}_2 \right)^* = \int dPS_3 \left( \text{diagram}_1 + \text{diagram}_2 \right) = \text{cut propagator diagram}$$

For N<sup>3</sup>LO ( $\alpha_s^3$ ) we need **cuts of 4-loop propagators**:

2-particle cuts

3-particle cuts

4-particle cuts

5-particle cuts

# Propagators and their cuts: state of the art

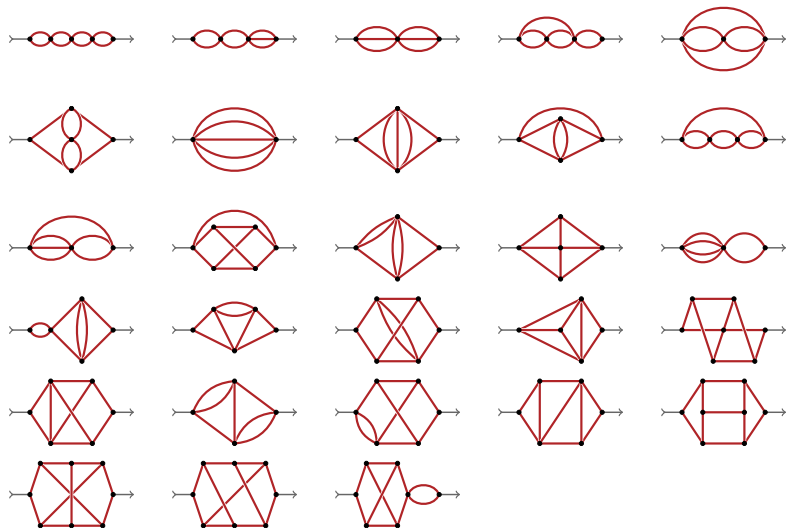

For **four loop propagators** we know:

- Virtual integrals. [Baikov, Chetyrkin '10]
- **Two**-particle cuts (3-loop form-factors).  
[Heinrich, Huber, Maitre '07; Heinrich, Huber, Kosower, Smirnov '09; Lee, Smirnov, Smirnov '10]
- **Five**-particle cuts (purely phase-space integrals). [Gituliar, V.M., Pikelner '18]
- **Three**- and **four**-particle cuts: **completed now**, this talk.

# Identifying cut masters

Start with the 28 master integrals for 4-loop propagators.

[Baikov, Chetyrkin '10]

# Identifying cut masters, II

Cut each virtual master in all possible ways.

Remove symmetric duplicate integrals.

$$\begin{array}{c} \text{Diagram 1} \\ \text{Diagram 2} \end{array} \Rightarrow \text{Diagram 3} = \left( \text{Diagram 4} \right)^* = \left( \text{Diagram 5} \right)^*$$

The diagram shows the reduction of symmetric duplicate integrals. It starts with two diagrams (one with a solid red top arc, one with a dashed top arc) that are equivalent to a single diagram with a dashed top arc. This is then shown to be equivalent to the complex conjugate of two other diagrams (one with a solid red top arc, one with a dashed top arc).

Done! There are **no additional IBP relations** between the remaining integrals. No additional master integrals either.

# 4-particle cut masters

There are 35 master integrals for 4-particle cuts.

# 4-particle cuts: direct analytic integration?

Integrate the 1-loop amplitude over the phase space?

$$\text{Cut Diagram} = \int \text{Triangle Diagram} \frac{1}{s_{13}s_{24}} d\text{PS}_4$$

4-particle phase-space has 5 degrees of freedom and **nontrivial shape**.

$$d\text{PS}_4 = (q^2)^{\frac{3d-8}{2}} 2^{1-2d} (2\pi)^{4-3d} \Omega_{d-1} \Omega_{d-2} \Omega_{d-3} (\Delta_4)^{\frac{d-5}{2}} \times \\ \Theta(\Delta_4) \Theta(s_{ij}) \delta\left(1 - \sum s_{ij}\right) ds_{12} ds_{13} ds_{14} ds_{23} ds_{24} ds_{34}$$

$$\Delta_4 = \det \begin{vmatrix} 0 & s_{12} & s_{13} & s_{14} \\ s_{12} & 0 & s_{23} & s_{24} \\ s_{13} & s_{23} & 0 & s_{34} \\ s_{14} & s_{24} & s_{34} & 0 \end{vmatrix}$$

# 4-particle cuts: direct analytic integration?

Integrate the 1-loop amplitude over the phase space?

$$\text{Box Diagram} = \int \text{Triangle Diagram} \frac{1}{s_{13}s_{24}} d\text{PS}_4$$

4-particle phase-space has 5 degrees of freedom and **nontrivial shape**.

Parametrisations exist that simplify that shape to a hypercube, e.g. the “**tripole parametrisation**”:

[Gehrmann-De Ridder, Gehrmann, Heinrich '03]

$$s_{12} \rightarrow (1-t)(1-y)(1-z)$$

$$s_{13} \rightarrow y(1-t-v+tv+tvz-2(1-2\xi)\sqrt{(1-t)(1-v)tvz})$$

$$s_{14} \rightarrow vy(1-z)$$

$$s_{23} \rightarrow z(1-y)$$

$$s_{24} \rightarrow t(1-y)(1-z)$$

$$s_{34} \rightarrow y(t-tv+ vz - tvz + 2(1-2\xi)\sqrt{(1-t)(1-v)tvz})$$

Such parametrisations contain roots, making analytic integration difficult.

# Dimensional recurrence relations

Using a parametric representation of integrals and the IBP tables, obtain **dimensional recurrence relations** (DRR) for each master  $I_i$ : [Tarasov '96; Lee '09]

$$I_i(d+2) = M_{ij}(d) I_j(d)$$

For 4-particle cuts, the DRR matrix  $M_{ij}$  is:

- **Triangular!** No coupled blocks, can be solved one by one.
- Has a factorizable diagonal of the form  $M_{ii} = C \prod_k (d/2 - a_k)^{n_k}$ .

The general solution is

$$I_i(d) = H_i(d) \omega(d) + R_i(d),$$

- $H_i$  is a **homogeneous solution**,  $H_i = C^{d/2} \prod_k \Gamma^{n_k}(d/2 - a_k)$ ;
- $R_i$  is a **particular solution**,  $R_i = -H_i(d) \sum_{k=d}^{\infty} H_i^{-1}(k+2) \sum_{j<i} M_{ij}(k) I_j(k)$ ;
- $\omega$  is an **arbitrary periodic function**,  $\omega(d+2) = \omega(d)$ , which can't be determined from DRR alone. Finding  $\omega(d)$  is the **main challenge**.

# 4-particle cut masters: fixing $\omega(d)$

1. Find  $d_0$ , such that  $I_i(d)$  is finite if  $\text{Re}(d) \in (d_0, d_0 + 2]$ .
  - 4-particle masters  $I_i$  mostly diverge at even  $d$ .
  - But  $J_i \equiv I_i / \langle \text{diagram} \rangle$  do not! All  $J_i$  are finite if  $\text{Re}(d) \in [6, 8]$ .
  - All homogeneous solutions  $H_i(d)$  can be chosen to be finite too.

# 4-particle cut masters: fixing $\omega(d)$

1. Find  $d_0$ , such that  $I_i(d)$  is finite if  $\text{Re}(d) \in (d_0, d_0 + 2]$ .
  - 4-particle masters  $I_i$  mostly diverge at even  $d$ .
  - But  $J_i \equiv I_i / \langle \text{diagram} \rangle$  do not! All  $J_i$  are finite if  $\text{Re}(d) \in [6, 8]$ .
  - All homogeneous solutions  $H_i(d)$  can be chosen to be finite too.
2. Find the poles of the particular solution  $R_i(d)$  by evaluating it numerically for many values of  $d$ .
  - Use **DREAM** for the evaluation.
  - All  $R_i(d)$  appear to be smooth.

[Lee, Mingulov '17]

# 4-particle cut masters: fixing $\omega(d)$

1. Find  $d_0$ , such that  $I_i(d)$  is finite if  $\text{Re}(d) \in (d_0, d_0 + 2]$ .
  - 4-particle masters  $I_i$  mostly diverge at even  $d$ .
  - But  $J_i \equiv I_i / \langle \text{diagram} \rangle$  do not! All  $J_i$  are finite if  $\text{Re}(d) \in [6, 8]$ .
  - All homogeneous solutions  $H_i(d)$  can be chosen to be finite too.
2. Find the poles of the particular solution  $R_i(d)$  by evaluating it numerically for many values of  $d$ .
  - Use **DREAM** for the evaluation. [Lee, Mingulov '17]
  - All  $R_i(d)$  appear to be smooth.
3. Construct an ansatz for  $\omega_i(d)$  looking at the poles of  $J_i$ ,  $H_i$ , and  $R_i$ .
  - We use  $C_0 + \sum C_i \cot\left(\frac{\pi}{2}(d - d_i)\right)$  or modifications.
  - For smooth  $J_i$ ,  $H_i$ , and  $R_i$  only one choice is possible: a constant,  $C_0$ .

# 4-particle cut masters: fixing $\omega(d)$

- Find  $d_0$ , such that  $I_i(d)$  is finite if  $\text{Re}(d) \in (d_0, d_0 + 2]$ .
  - 4-particle masters  $I_i$  mostly diverge at even  $d$ .
  - But  $J_i \equiv I_i / \text{[diagram]}$  do not! All  $J_i$  are finite if  $\text{Re}(d) \in [6, 8]$ .
  - All homogeneous solutions  $H_i(d)$  can be chosen to be finite too.
- Find the poles of the particular solution  $R_i(d)$  by evaluating it numerically for many values of  $d$ .
  - Use **DREAM** for the evaluation. [Lee, Mingulov '17]
  - All  $R_i(d)$  appear to be smooth.
- Construct an ansatz for  $\omega_i(d)$  looking at the poles of  $J_i$ ,  $H_i$ , and  $R_i$ .
  - We use  $C_0 + \sum C_i \cot\left(\frac{\pi}{2}(d - d_i)\right)$  or modifications.
  - For smooth  $J_i$ ,  $H_i$ , and  $R_i$  only one choice is possible: a constant,  $C_0$ .
- Fix the constants in the ansatz from various considerations.
  - The leading pole of  $I_i$  can be calculated by inserting a mass in the loop, and looking at large mass expansion of the integral—this is enough to fix one constant.
  - Turns out  $\omega_i(d) = 0$  for all integrals, except for three trivial integrals:

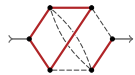

## 4-particle cut masters, wrap up

Once  $\omega_i$  are fixed, the masters can be evaluated with **SummerTime** or **DREAM** numerically to arbitrary precision, and then restored in terms of MZVs via PSLQ.

Example result:

$$= \frac{\left( \text{Diagram with two loops} \right)^*}{(q^2)^3} \left[ -6\zeta_2 \frac{1}{\epsilon^2} + \left( 59\zeta_2 - 60\zeta_3 \right) \frac{1}{\epsilon} + \left( -203\zeta_2 + \right. \right. \\ \left. \left. + 590\zeta_3 - 129\zeta_2^2 \right) + \left( 288\zeta_2 - 2030\zeta_3 + \frac{2537}{2}\zeta_2^2 + \right. \right. \\ \left. \left. + 192\zeta_2\zeta_3 - 1806\zeta_5 \right) \epsilon + \mathcal{O}(\epsilon^2) \right]$$

Overall, we've restored the series up to MZVs of weight 12. They have poles up to  $1/\epsilon^5$ . Zetas up to weight 6 in the  $\epsilon$ -finite part.

# 4-particle cut masters, numerical checks

Numerical evaluation:

- Feynman parameterization of the loop amplitudes.
  - 1-loop amplitude—all the UV divergence is in the prefactor of the parameterization, the integral part is finite.
- Tripole parameterization of the phase space. [Gehrmann-De Ridder et al. '03]
- Direct Monte-Carlo integration of the result.
  - Converges, because the divergent prefactor is separated!
- Checked at many different values of  $d$ .

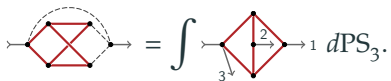

# 3-particle cut masters

There are 27 master integrals among the 3-particle cuts.

# How to calculate 3-particle cuts?

Split integrals into the 2-loop 1→3 amplitude and 3-particle phase space,

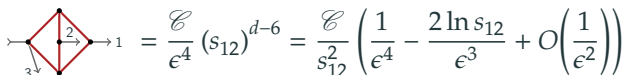

The diagram shows an equality between two expressions. On the left is a 2-loop 1→3 amplitude represented by a red diamond with two internal lines forming a square, and a dashed arc above it. On the right is an integral over a 2-loop 1→3 amplitude (a red diamond with a vertical line and a horizontal line) multiplied by the 3-particle phase space  $dPS_3$ . The diamond on the right has external legs labeled 1, 2, and 3.

Parameterize the phase-space via  $s_{ij} = (p_i + p_j)^2 / q^2$ ,

$$dPS_3 = (q^2)^{d-3} \frac{2^{4-3d} \pi^{\frac{3}{2}-d}}{\Gamma\left(\frac{d-2}{2}\right) \Gamma\left(\frac{d-1}{2}\right)} (s_{12} s_{13} s_{23})^{\frac{d-4}{2}} \delta(1 - \sum s_{ij}) \prod ds_{ij}.$$

Insert 2-loop 1→3 amplitudes as series in  $\epsilon$  in terms of multiple polylogarithms depending on  $s_{12}$  and  $s_{13}$ :

The diagram shows a 2-loop 1→3 amplitude (a red diamond with a vertical line and a horizontal line) equal to a series expansion in  $\epsilon$ . The expansion is  $\frac{\mathcal{C}}{\epsilon^4} (s_{12})^{d-6} = \frac{\mathcal{C}}{s_{12}^2} \left( \frac{1}{\epsilon^4} - \frac{2 \ln s_{12}}{\epsilon^3} + O\left(\frac{1}{\epsilon^2}\right) \right)$ . The diamond on the left has external legs labeled 1, 2, and 3.

Multiply series and **integrate order by order?**

# How to calculate 3-particle cuts, II

Integration of the series does not converge:

$$\int \text{[Diagram]} d\text{PS}_3 = \int \frac{\mathcal{C}}{s_{12}^2} \left( \frac{1}{\epsilon^4} - \frac{2 \ln s_{12}}{\epsilon^3} + O\left(\frac{1}{\epsilon^2}\right) \right) d\text{PS}_3 = \frac{\infty}{\epsilon^4} + \frac{\infty}{\epsilon^3} + \dots$$

Taking series after integration does:

$$\int \text{[Diagram]} d\text{PS}_3 = \int \frac{\mathcal{C}}{\epsilon^4} (s_{12})^{d-6} d\text{PS}_3 = \frac{\mathcal{H}}{\epsilon^5} + \frac{\mathcal{H}'}{\epsilon^4} + \dots$$

Problem: the integral is **not infrared-finite** (in 4 dimensions).

Solution: look at the same integrals in  $d = 6 - 2\epsilon$ , which are. Taking series and integrating order-by-order will commute there.

# Aside: 2-loop 1→3 amplitudes

28 in total, not counting  $\{p_1, p_2, p_3\}$  permutations.

# Aside: 2-loop 1→3 amplitudes, II

First computed up to weight 4 by Gehrmann and Remiddi, recomputed to weight 8 by us.

- Higher weights are needed because the  $\epsilon$ -finite part of the cut integrals contain MZVs up to weight 6.

To compute:

[Gehrmann, Remiddi '00, '01]

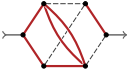

- Write down the **differential equations** in  $s_{12}$  and  $s_{13}$ .
- Find the  **$\epsilon$ -form in 2 variables** (automatized by the new **Fuchsia**) and construct the general solution. [\[github.com/magv/fuchsia.cpp\]](https://github.com/magv/fuchsia.cpp)
  - The general form is  $\sum \mathcal{R}(s_{ij}, \mathcal{E}) G(\{0, 1, 1 - s_{13}, -s_{13}\}; s_{12}) G(\{0, 1\}; s_{13})$ .
- Fix the **integration constants**  $\mathcal{E}$  by:
  - matching with known single-scale integrals;
  - enforcing regularity at  $s_{ij} \rightarrow 1$  (because the integrals are massless);
  - enforcing regularity at  $s_{ij} \rightarrow 0$  for planar integrals if  $i$  and  $j$  are not adjacent.

# How to calculate 3-particle cuts, III

In summary:

1. Use dimensional recurrence for the  $1 \rightarrow 3$  amplitudes to get them as series around  $d = 6 - 2\epsilon$ .
2. Multiply by  $\epsilon$ -expansion of  $d\text{PS}_3$ , integrate order by order.
3. Use dimensional recurrence for the cut integrals to lower the series to  $4 - 2\epsilon$ .

Example result:

The diagram shows a hexagon with two vertices on the left and two on the right. The top and bottom edges are solid lines, while the left and right edges are dashed lines. Two red ovals are drawn on the top edge, representing a cut. A dashed line connects the two vertices on the right, also representing a cut.

$$= \frac{\text{diagram}}{(q^2)^2} \left[ 2\zeta_2 \frac{1}{\epsilon} + \left( -13\zeta_2 + 16\zeta_3 \right) + \left( 27\zeta_2 - \right. \right. \\ \left. \left. - 104\zeta_3 + \frac{156}{5}\zeta_2^2 \right) \epsilon + \left( -18\zeta_2 + 216\zeta_3 - \frac{1014}{5}\zeta_2^2 - \right. \right. \\ \left. \left. - 90\zeta_2\zeta_3 + 448\zeta_5 \right) \epsilon^2 + \mathcal{O}(\epsilon^3) \right]$$

Overall, series up to MZVs of weight 8. Poles up to  $1/\epsilon^6$ . Zetas up to weight 6 in the  $\epsilon$ -finite part.

# 3-particle cut masters, numerical checks

Numerical evaluation:

- Feynman parameterization for the loop amplitude.
- Direct parameterization of the phase space in Mandelstam variables.
- Sector decomposition with **FIESTA**. [Smirnov '15]
- Checked in  $d = 6 - 2\epsilon$ , and  $8 - 2\epsilon$ . Too slow in  $4 - 2\epsilon$ .

# Cutkosky rules check

Cutkosky rules for each Feynman diagram  $F$ :

$$F + F^* = - \sum_i \text{Cut}_i F$$

To use this simple form, add Feynman rules to the integrals:

$$\begin{aligned} \text{---} \diagup \text{---} &= \text{---} \diagdown \text{---} = \text{---} \times \text{---} = \dots = i & \text{---} \overset{p}{\text{---}} \text{---} &= \frac{i}{p^2 + i0} & \text{---} \overset{p}{\text{---}} \text{---} &= 2\pi\delta^+(p^2) \end{aligned}$$

Then, for each of the 31 propagator master:

$$\begin{aligned} 2 \text{Im} \text{---} \text{---} \text{---} &= 2 \text{Re} \text{---} \text{---} \text{---} + 4 \text{Im} \text{---} \text{---} \text{---} - 4 \text{---} \text{---} \text{---} \text{---} \text{---} \text{---} \text{---} \\ 2 \text{Im} \text{---} \text{---} \text{---} &= 2 \text{Re} \text{---} \text{---} \text{---} + 4 \text{Im} \text{---} \text{---} \text{---} - 2 \text{---} \text{---} \text{---} \text{---} \text{---} \text{---} \\ &\dots \end{aligned}$$

All cuts are now known (at least to weight 8)! Insert them here to check the result consistency.

# 3-particle cut masters via DRR

Bonus: solve DRR for 3-particle cuts too, using everything calculated so far.

- The **simple case**: only one 3-particle cut in a Cutkosky relation.

$$2 \operatorname{Im} \left[ \text{Diagram 1} \right] = I \left[ \text{Diagram 2} \right] - \left[ \text{Diagram 3} \right] - I \left[ \text{Diagram 4} \right] + \left[ \text{Diagram 5} \right]$$

known to  $\zeta_{12}$ 
just calculated
3-particle cut

- The **complex case**: multiple 3-particle cuts enter a Cutkosky relation.

$$2 \operatorname{Im} \left[ \text{Diagram 1} \right] = -2I \left[ \text{Diagram 2} \right] - I \left[ \text{Diagram 3} \right] + I \left[ \text{Diagram 4} \right] - 2 \left[ \text{Diagram 5} \right] + I \left[ \text{Diagram 6} \right] + 2 \left[ \text{Diagram 7} \right] + \left[ \text{Diagram 8} \right] - \left[ \text{Diagram 9} \right]$$

3-particle cuts

- Only the sum is constrained, but we have also calculated the expansion to weight 8 of these integrals—**enough information** in total to fix the constants in the  $\omega_i(d)$  ansatz, and **solve the DRR completely!**

Result: all 3-particle cut masters upgraded from fixed weight 8 series to any-weight any- $d$  DRR solutions.

# Summary

- Master integrals for:
  - 3-particle (+ 2-loop) cuts of 4-loop propagators;
  - 4-particle (+ 1-loop) cuts of 4-loop propagators.
- Results as series in  $\epsilon$ , up to MZVs of weight 12.
- Bonus:
  - **SummerTime** files to expand around any  $d$  with arbitrary precision.
  - For convenience, results for all other cuts included too.
  - Master integrals for 2-loop  $1 \rightarrow 3$  amplitudes up to weight 8.
- To be published shortly.

# Summary

- Master integrals for:
  - 3-particle (+ 2-loop) cuts of 4-loop propagators;
  - 4-particle (+ 1-loop) cuts of 4-loop propagators.
- Results as series in  $\epsilon$ , up to MZVs of weight 12.
- Bonus:
  - **SummerTime** files to expand around any  $d$  with arbitrary precision.
  - For convenience, results for all other cuts included too.
  - Master integrals for 2-loop  $1 \rightarrow 3$  amplitudes up to weight 8.
- To be published shortly.

Thank you for your attention.
