# ATLAS Inner Tracker

- Current ATLAS Inner Detector is designed for:
  - 10 years of operation
  - Instantaneous luminosity of  $1.0 \cdot 10^{34} \text{ cm}^{-2} \text{ s}^{-1}$
  - Average pile-up  $\langle \mu \rangle = 23$
  - Radiation damage equivalent to an integrated luminosity of  $400 \text{ fb}^{-1}$  for pixel detector,  $700 \text{ fb}^{-1}$  for SCT and  $850 \text{ fb}^{-1}$  for IBL (based on component technology and distance from the beam)
- Upgrade required to cope with performance of HL-LHC  
⇒ ATLAS Inner Tracker (ITk) designed for:
  - 10 years of operation
  - Instantaneous luminosity of  $7.5 \cdot 10^{34} \text{ cm}^{-2} \text{ s}^{-1}$
  - Average pile-up  $\langle \mu \rangle = 200$
  - Radiation damage of  $4000 \text{ fb}^{-1}$

## ATLAS ITk Layout

- Layout consists of a central barrel region and two end-caps.
- Pixel detector (pictured red)
  - 5 barrel module layers
  - many end-cap module rings
- Strip detector (pictured blue)
  - 4 barrel module layers
  - 6 end-cap module discs

## Strip detector local support structures

- Barrel strip modules (2 types) organised in staves
- End-cap strip modules (6 types) organised in wedge-shaped petals, segmented into rings (R0-R5)
- Local supports (staves and petals) provide mechanical rigidity and house the common electrical and cooling services
- Power and data links channeled through an end-of-substructure card

# Strip module

- Strip module consists of
  - Silicon-strip sensor (type n<sup>+</sup>-in-p)
  - Hybrid = PCB + read-out ASIC chips (ABCStar, HCCStar)
  - Power board (DC-DC converter, AMACv2 monitoring chip, HV multiplexer)
- Strips bonded to ABCStar chips
- Barrel and end-cap modules feature the same component groups, but differ in size, shape, number of chips, etc.

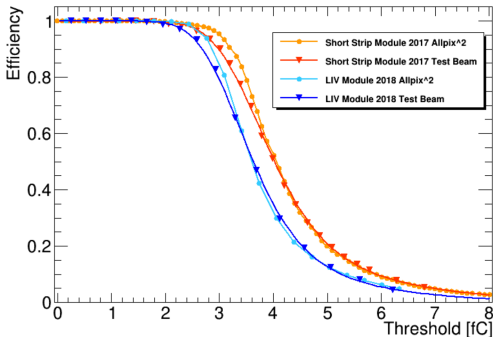

Short-strip barrel module

## Module characterisation

- Threshold scan – basis for module (ABC chip) characterisation
  - Injecting a constant charge and varying the threshold value of a discriminator from 0 to max.
  - Multiple charge injections at each threshold value
  - Plotting average hit rate for each threshold value  $\Rightarrow$  S-curve
  - Value with 50% hit rate ( $V_{t50}$ ) = median of the injected charge
- Gain and noise of a chip obtainable from threshold-scanning with different charges

# AIPix<sup>2</sup> Framework

## Introduction

- Generic simulation framework for silicon tracker and vertex detectors.
- Written in C++.
- Relies on Geant4, ROOT and Eigen3 libraries.
- Modular  $\Rightarrow$  easy extension to more complex simulations.
- Three configuration files required to run a simulation:
  - **Main** – global framework configuration with a list of modules to instantiate
  - **Geometry** – position, orientation and model type of detectors.
  - **Model** – parameters describing a particular type of a detector.

## Detector model

- Very simple creation of a basic silicon pixel (strip) detector
- Allows addition of support structures to increase accuracy of a model

```
number_of_pixels = 1280 1  
pixel_size = 74.5um 10cm  
sensor_thickness = 300um
```

```
[support]  
thickness = 1um  
size = 5cm 5cm  
location = "absolute"  
offset = 0 0 -5cm  
material = "kapton"
```

```
[support]
```

```
...
```

## Experiment geometry

- Straightforward placement and orientation of uniquely named detectors
- Detector types must be specified

```
[dut]  
type = "timepix"  
position = 0 0 0  
orientation = 0 0 0
```

```
[mimosa1]  
type = "mimosa23"  
position = 0 0 -6cm  
orientation = 0 0 90deg
```

...

## Main configuration

- Main configuration file in an easy-to-read format
- Consists of several modules (headers in [ ] brackets) with self-explanatory parameters (mandatory and optional)

```
[AIPix]
```

```
# Main module
```

```
detectors_file = "geometry.conf"
```

```
log_level = "STATUS"
```

```
number_of_events = 50000
```

```
[GeometryBuilderGeant4]
```

```
# Constructs the Geant4 geometry
```

```
[DepositionGeant4]
```

```
# Deposits charge carriers in the active volume of all detectors
```

```
physics_list = FTFP_BERT_LIV
```

```
particle_type = "e-"
```

```
source_energy = 4.4GeV
```

```
source_position = 0 0 -500um
```

```
beam_direction = 0 0 1
```

```
beam_size = 1mm
```

## Main configuration

### [ElectricFieldReader]

*# Adds an electric field to the detector*

model = "linear"

bias\_voltage = -400V

depletion\_voltage = -360V

### [GenericPropagation]

*# Simulates the propagation of charge carriers through the sensitive volume of the detector*

temperature = 290K

charge\_per\_step = 10

### [SimpleTransfer]

*# Prepares sets of propagated charges for processing*

### [DefaultDigitizer]

*# translates the collected charges into a digitized signal*

electronics\_noise = 643e

threshold = 1e

adc\_smearing = 1e

### [ROOTObjectWriter]

*# Reads all messages dispatched by the framework and stores specified objects*

file\_name = "output.root"

# Simulation Results

- Simulation of passage of 50 000 particles
- Efficiency and average cluster size plots obtained
- Comparison with available testbeam data from 2017
  - short-strip barrel module with ATLAS12 sensor
  - DESY – 4.4 GeV  $e^-$
- Simulation of different angles of incidence

- Efficiency of the simulated module compared with testbeam data
- Good agreement except for the “efficiency drop” area

## Efficiency – fit function

- Efficiency fitted with a skewed complementary error function (erfc)

$$f(x) = 0.5 \cdot [0] \cdot \operatorname{erfc} \left( \frac{x-[1]}{\sqrt{2} \cdot [2]} \cdot \left[ 1 - [3] \cdot \tanh \left( \frac{[4] \cdot (x-[1])}{\sqrt{2} \cdot [2]} \right) \right] \right)$$

Parameter meaning:

- [0] – normalization
- [1] – median charge
- [2] – “ $\sigma$ ”
- [3], [4] – skew parameters

## Cluster size

- Average cluster size (number of neighboring strips with a hit) compared with testbeam data
- Noticeable offset between simulation and testbeam results, although the shape of the curves is similar

## Different angles - cluster size

- Average cluster size for different incidence angles
- Higher average cluster size for larger angles, especially at low thresholds – particle itself passes through multiple strips

## Different angles - efficiency

- Efficiency for different incidence angles
- For higher angles total deposited energy is split among multiple strips  $\Rightarrow$  harder to pass the threshold in each strip and the curve drops sooner
- Fit function doesn't accurately describe the efficiency drop area, more noticeable for some angles than others ( $5^\circ$  and  $20^\circ$ )

## Validation of Athena digitization

- ITk will use  $n^+$ -in-p sensor type, whereas SCT uses  $p^+$ -in-n type  $\Rightarrow$  transport of different charge carriers (electrons and holes respectively)
- Unclear whether Athena can accurately simulate  $n^+$ -in-p sensor type.
- Verification possible by comparing Athena simulation results with
  - testbeam data (complicated, currently only data for perpendicular incidence and no magnetic field exist)
  - AllPix<sup>2</sup> simulations
