OUTLOOK

- Motivation
- What we see in LHC beams
- Simulation benchmarking in LHC
- Prediction for HL-LHC
- Conclusions

Introduction

GOAL

- estimate if/when the noise from the power converters impact the **HL-LHC beam performance**

METHOD

- analyze the effect of the power converter noise in LHC
- build a general framework for simulations and benchmark against LHC observations
- make predictions for HL-LHC

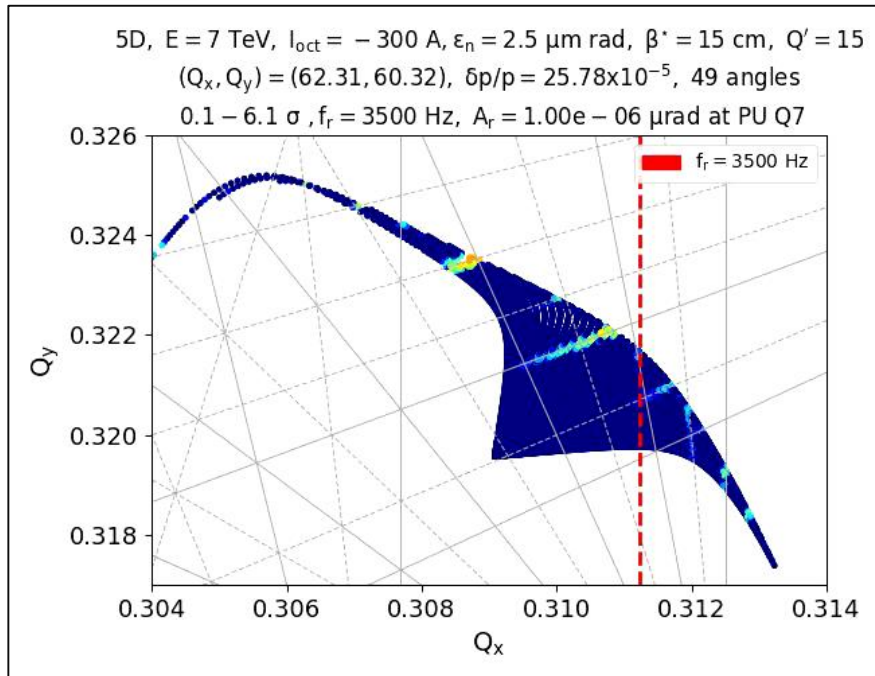

WORKING FOCUS

- We will address the **dipolar and quadrupolar** noise.

Introduction

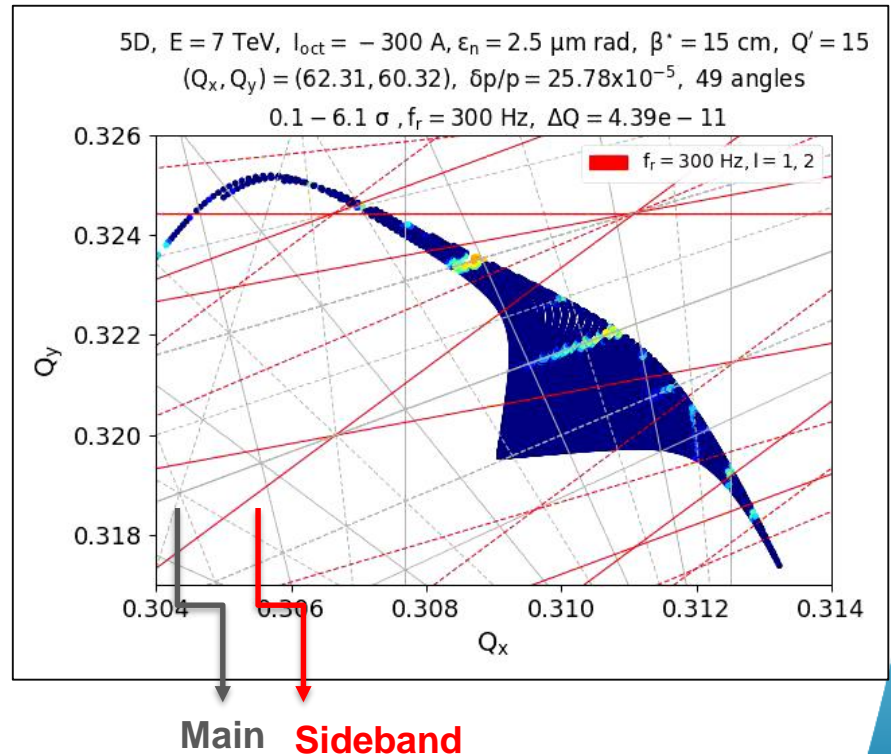

1. Dipolar modulation largest impact close to the tune

3.5 kHz

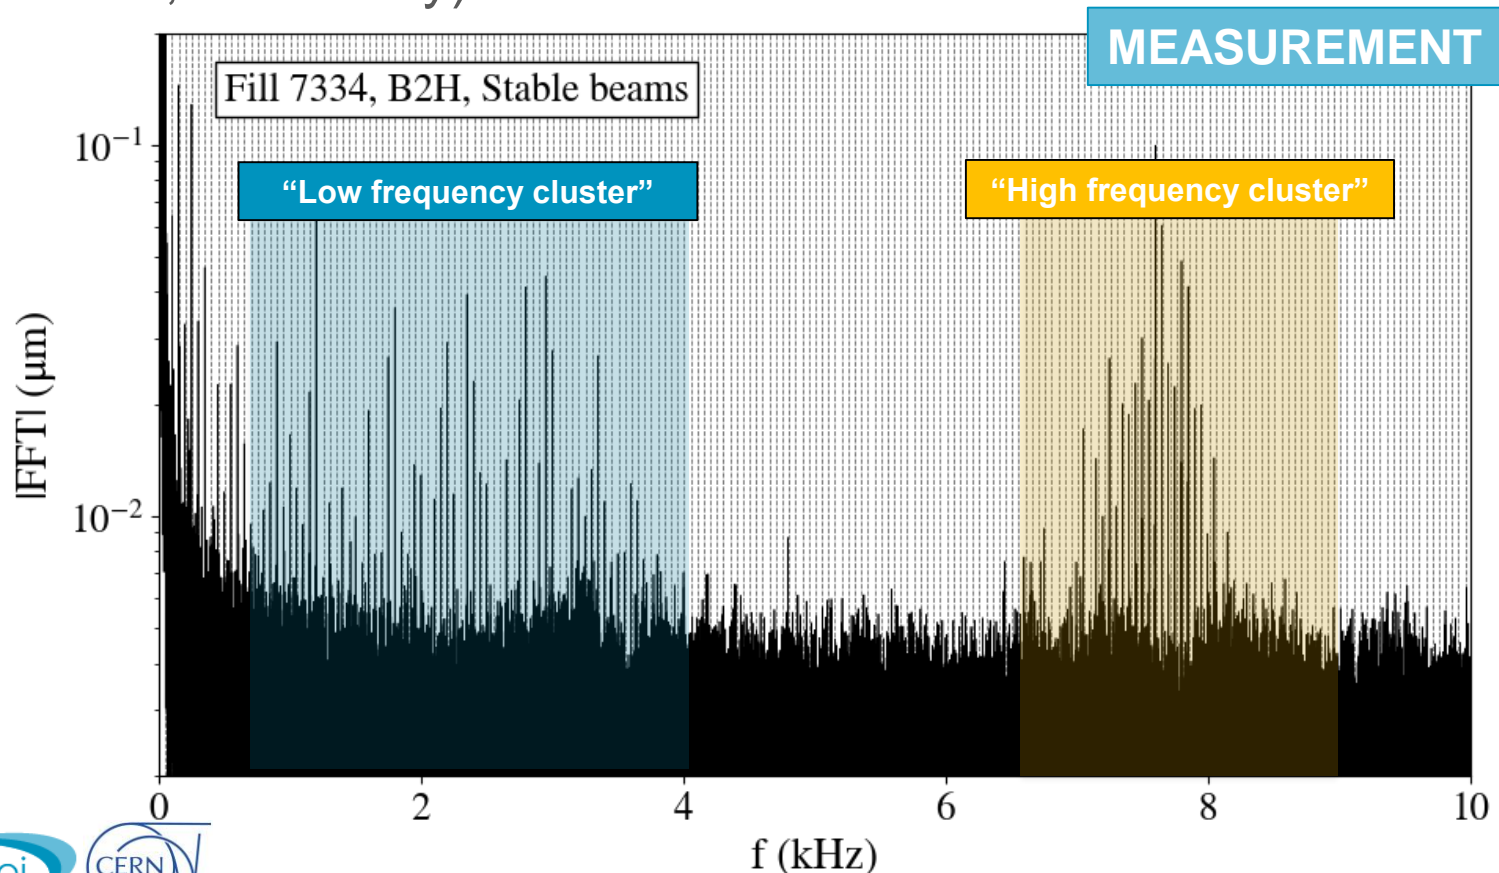

2. Quadrupolar modulation possible large impact even at frequencies far away from the tune

300 Hz

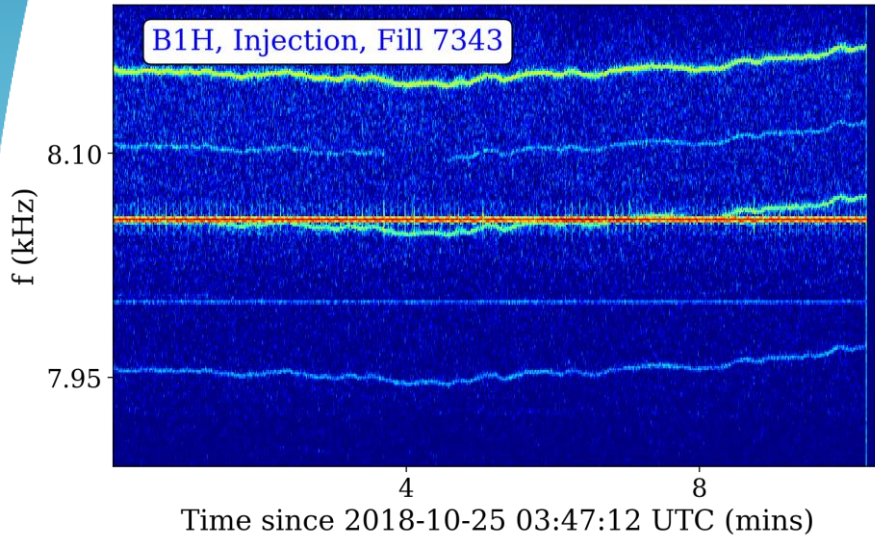

Observations in LHC beam spectrum

- In the LHC we see **only dipolar oscillations**
- Those tones are dominated by **50 Hz harmonics**. Visible in several instruments (BBQ, MIM, DOROS, ADTObBox).
- **ADTObBox** will be our privileged system (bbb, calibrated metric, sensitivity).

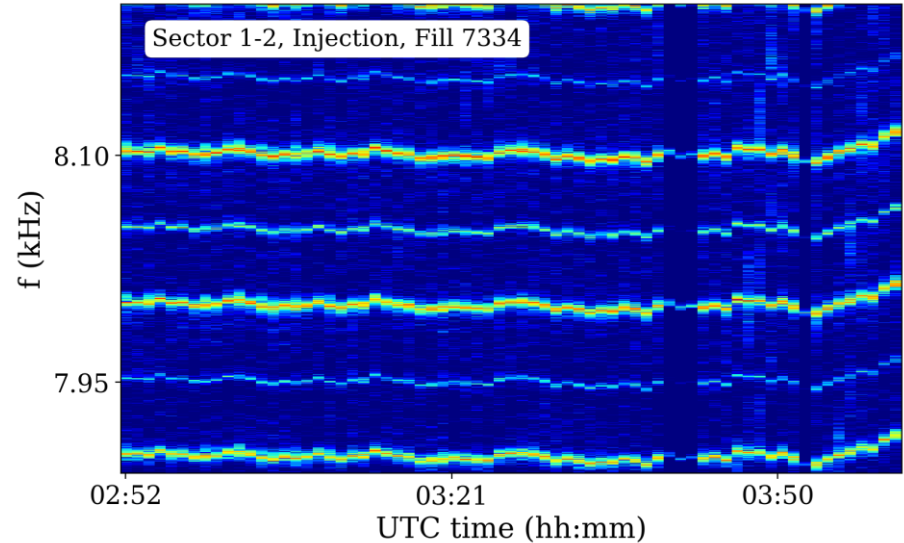

50 Hz harmonics

B1H, Injection

MB Power converter V S1-2

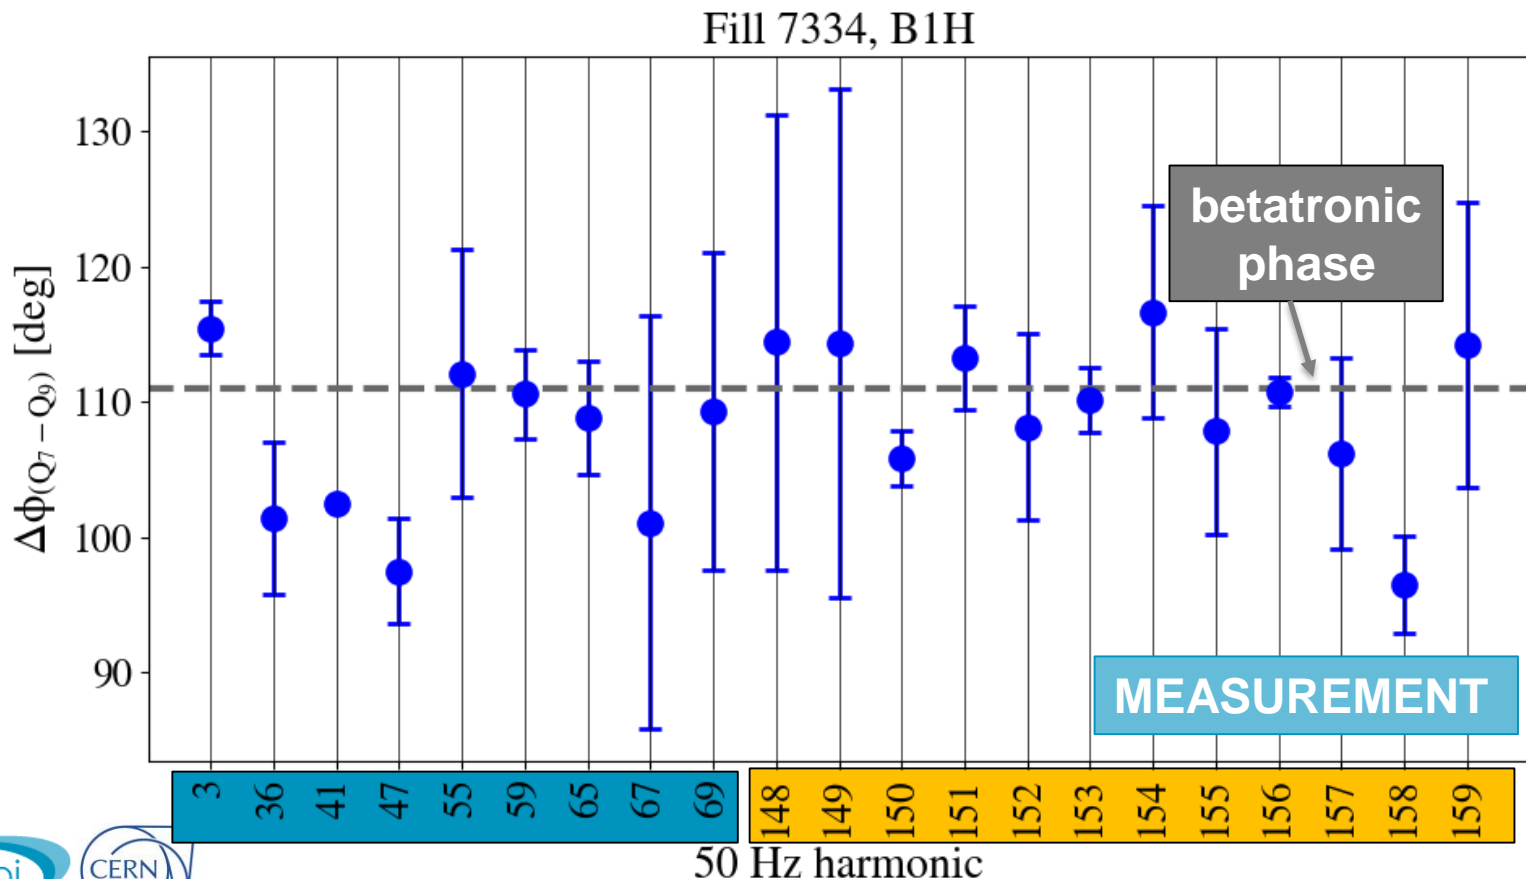

- Clear correlation between the 50 Hz harmonics.

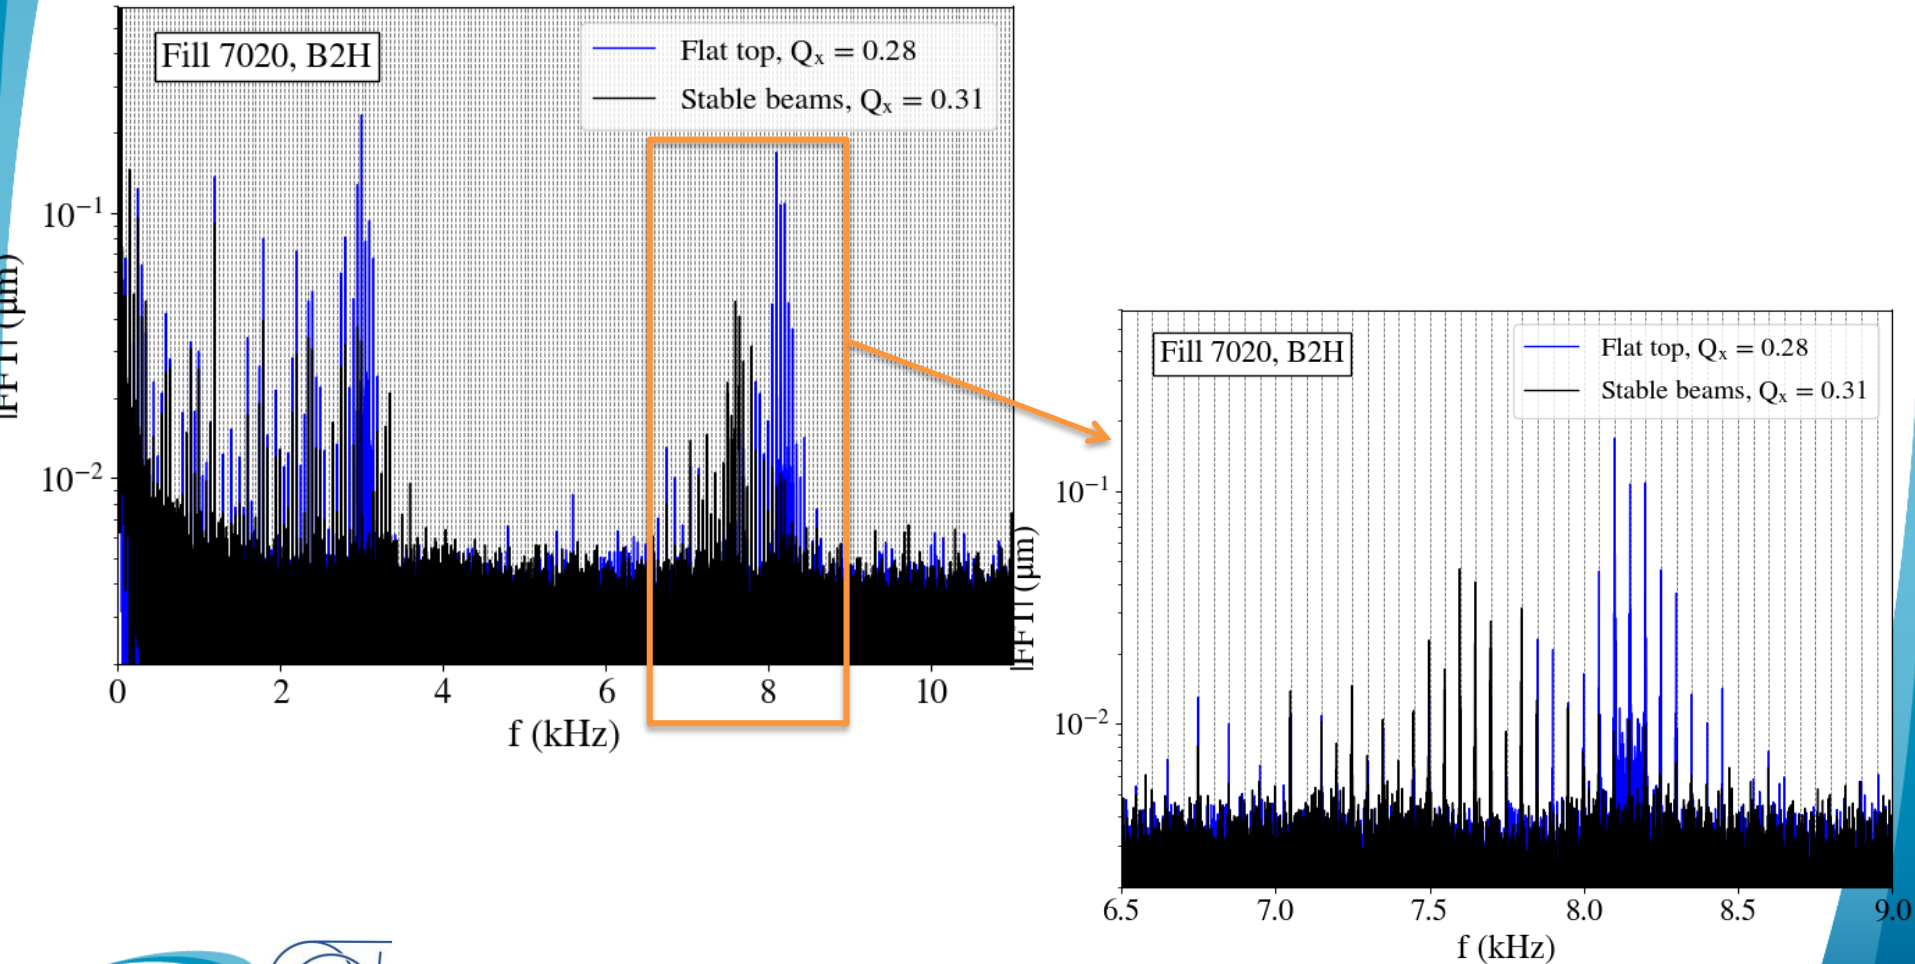

Are these tones an artefact? **No.**

- The phase difference between 2 close-by BPMs (Q7 and Q9) for a given tone corresponds to the betatronic phase advance between Q7-Q9.

Are these tones an artefact? **No.**

- Changing the tune there is a visible impact on the spectrum.

Which beam? which plane?

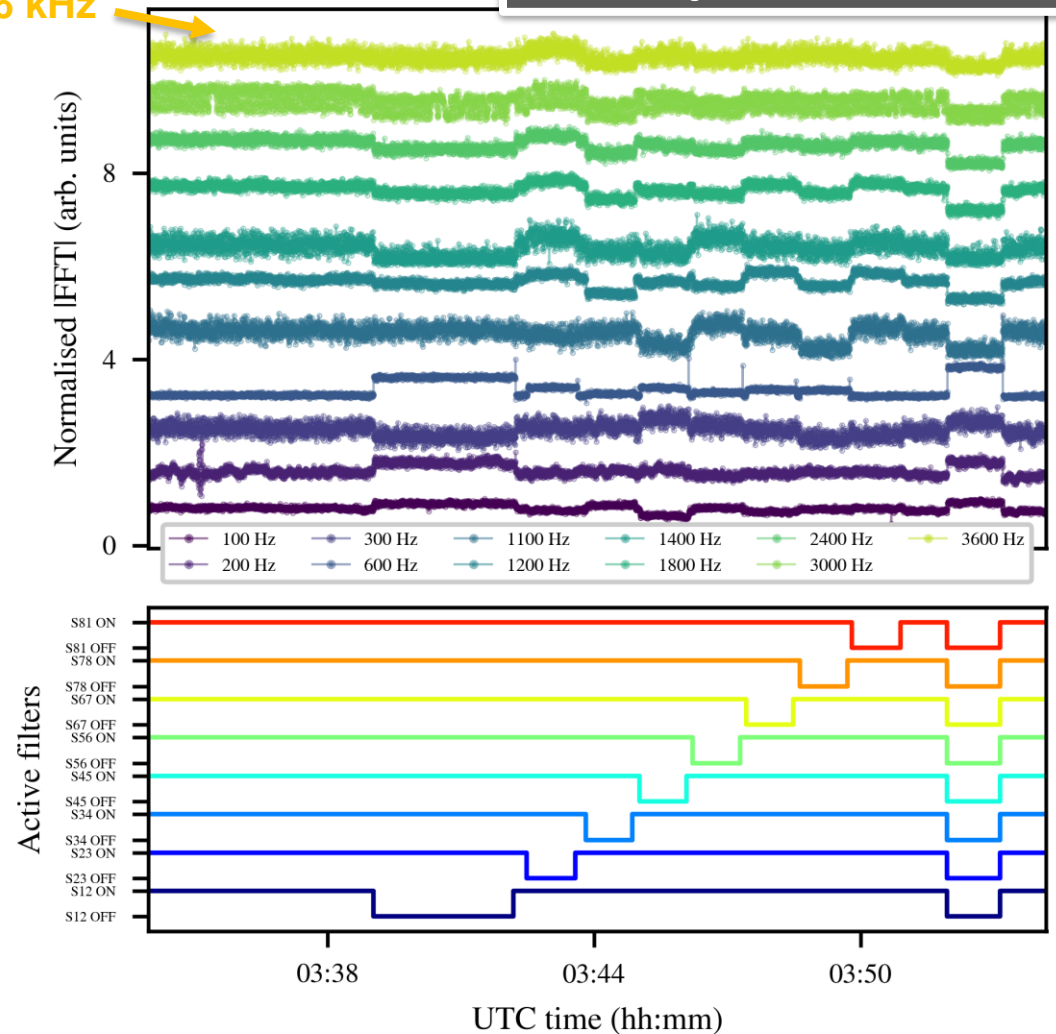

- B1 more excited than B2.
- H-plane more than V-plane (→ **main bends**).
- **High frequency cluster (surprisingly) strong.**

Impact of the main bends power supplies

- For **lower frequencies**, effect of the Sector Dipoles Active filters.
- → main dipoles are clearly a contributors.

3.6 kHz

B1H, Injection, Fill 7343

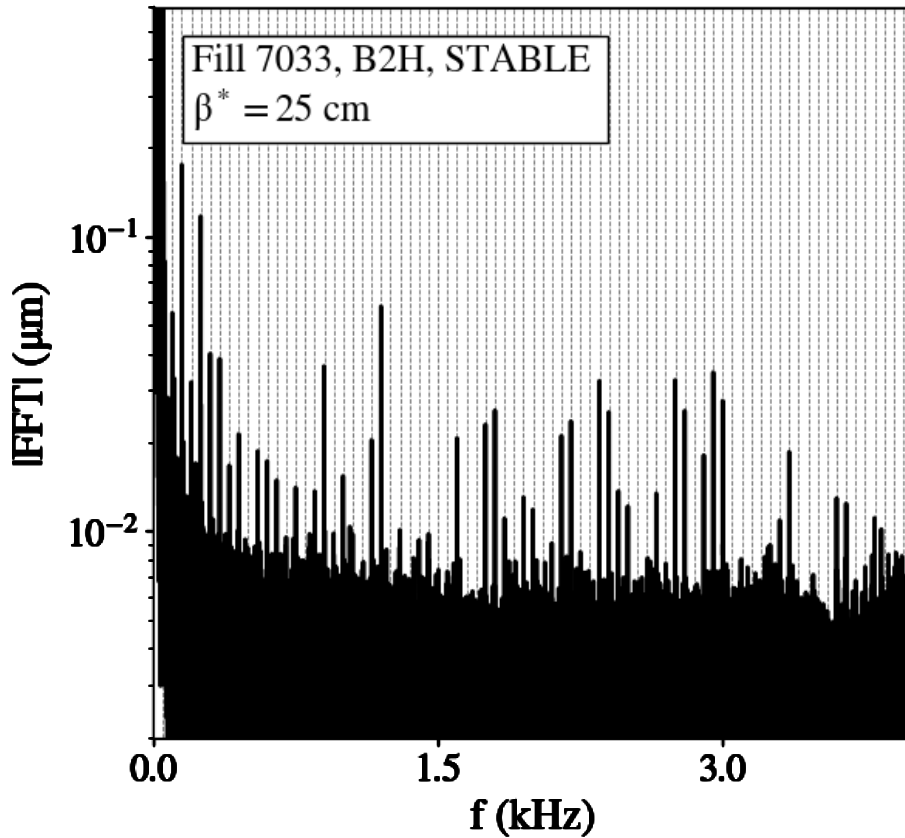

What is the equivalent kick?

$\theta_{noise} = 1e-11$ rad at $\beta_{noise} = 100$ m

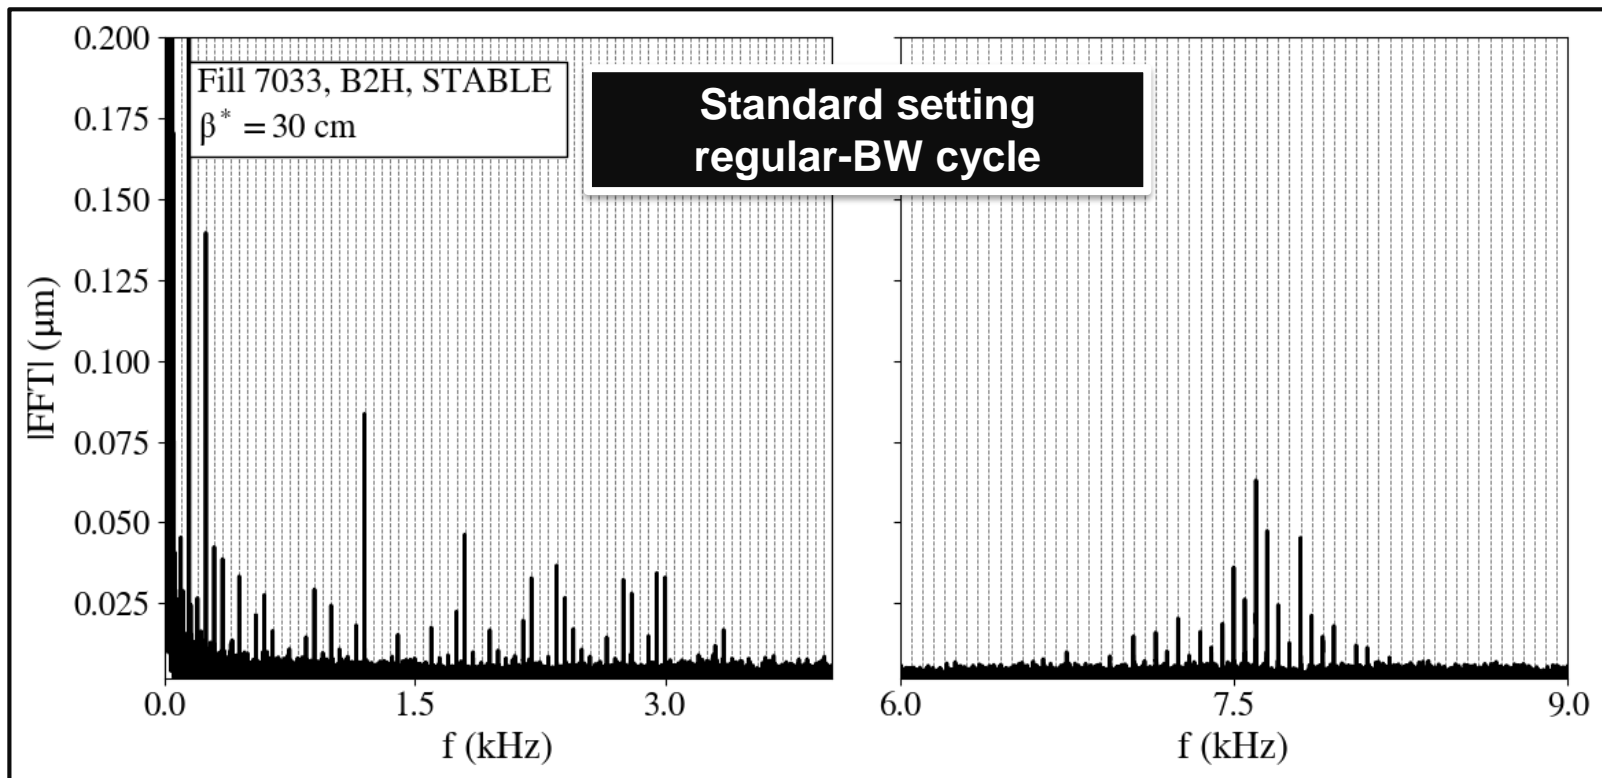

- As reference, a single kick of $\theta = 1e-11$ rad at $\beta = 100$ m gives oscillation in the order of $1e-3 \sigma$ (as observed).
- $1e-11$ rad has to be compared with the kick of the main bend (~ 5 mrad)
- It would be equivalent to $2e-9$ stability of one single MB at a frequency $1e-3$ apart from the tune.

Is the picture beam mode dependent? **Mildly.**

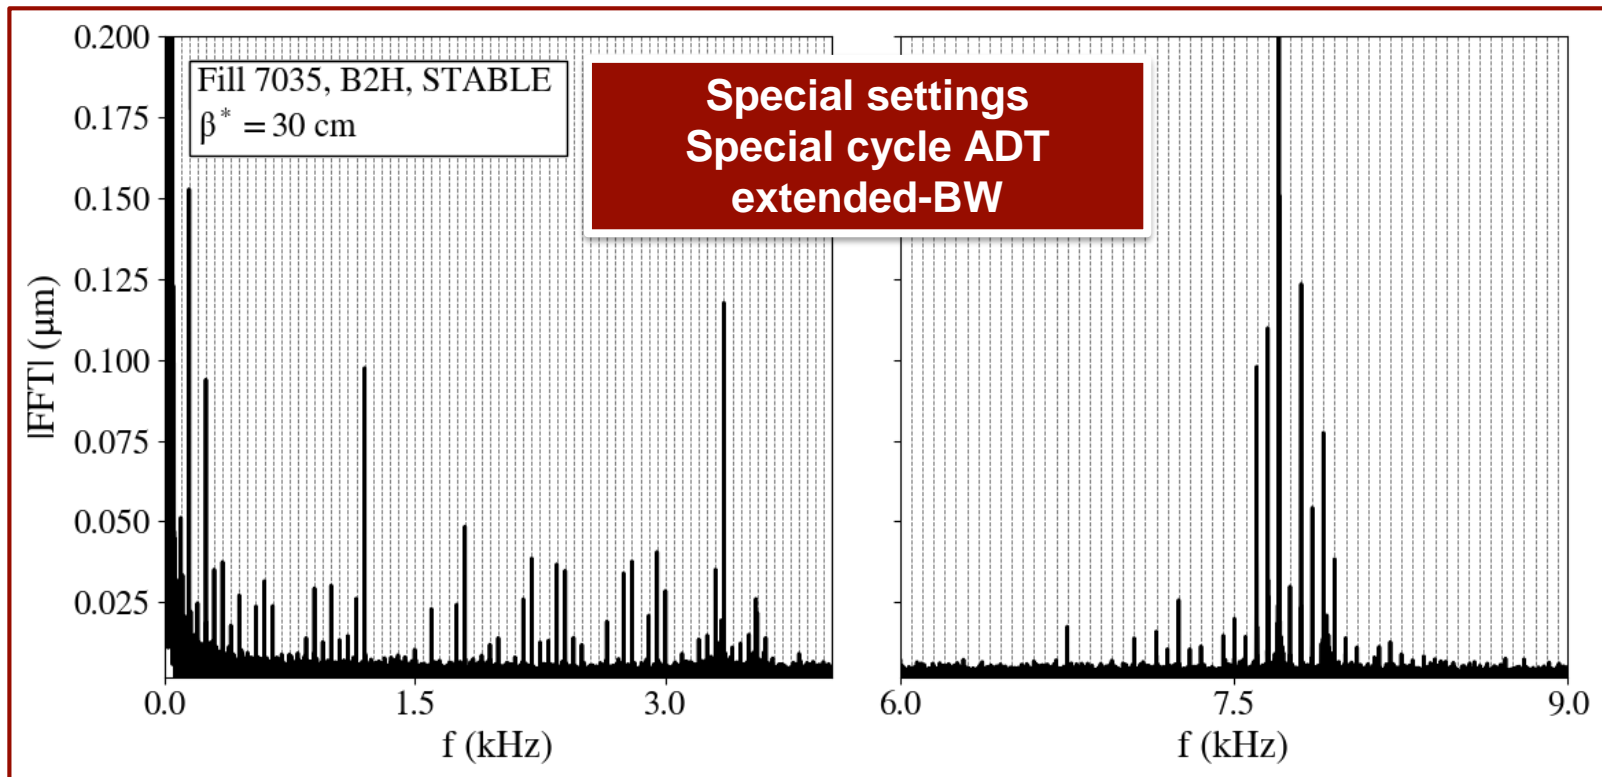

Does the damper enter in the game? **Yes.**

- Beam spectrum could be further attenuated by the damper.
- Reducing the damper affect 50 Hz harmonics.

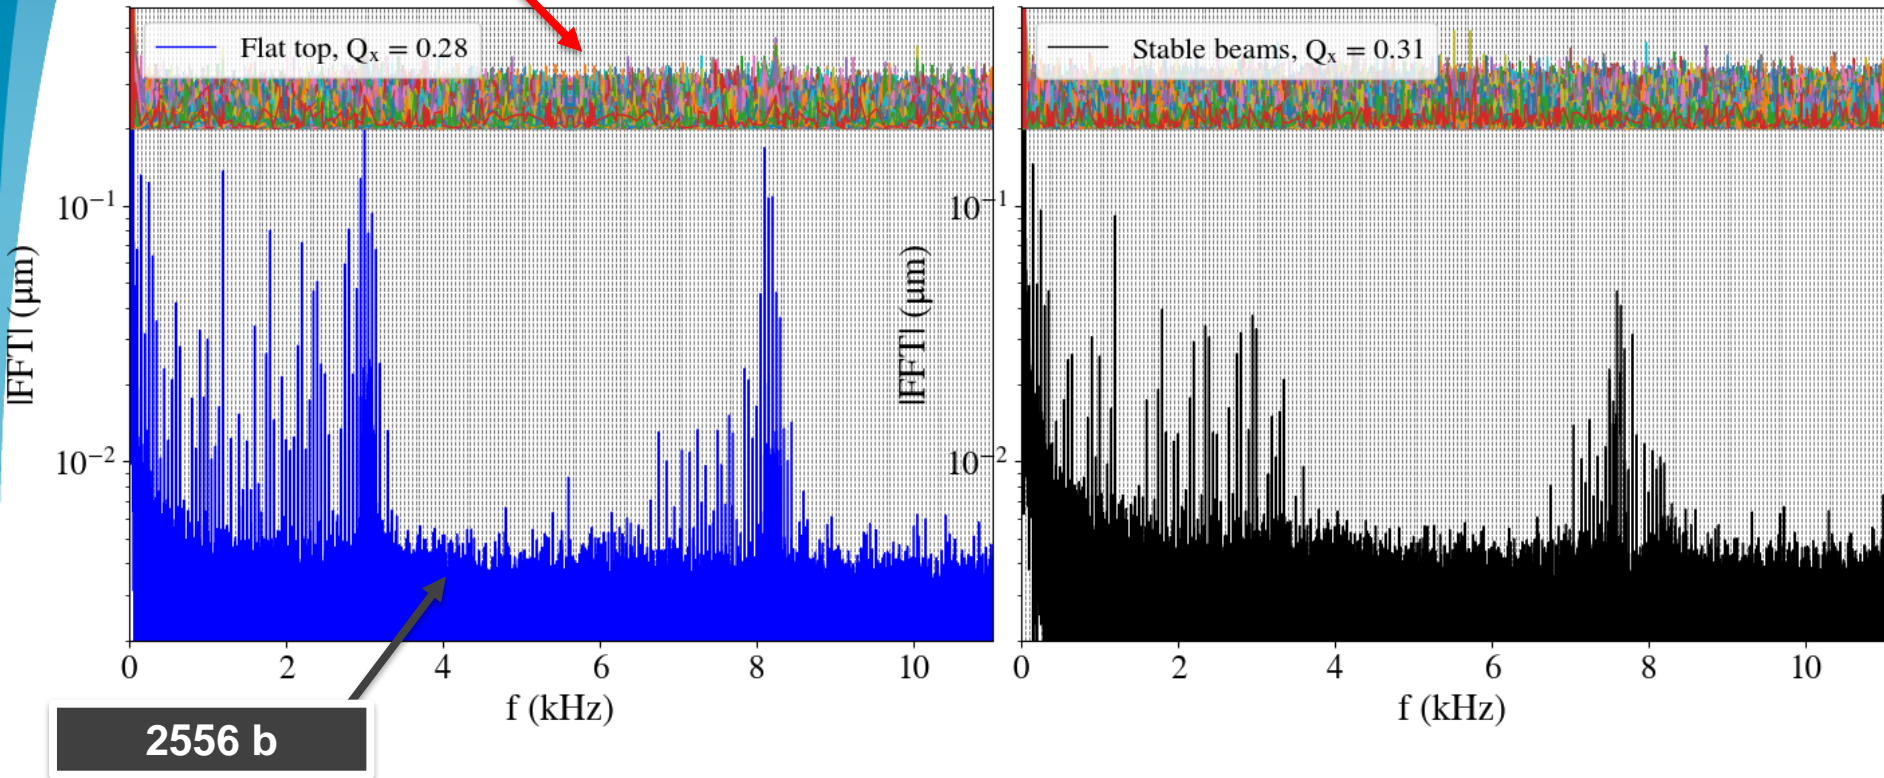

Does the damper enter in the game? **Yes.**

- Beam spectrum could be further attenuated by the damper.
- Reducing the damper affect 50 Hz harmonics.

Single-bunch spectrum vs beam-spectrum

Single bunch

- The measured beam spectrum is below the single bunch spectrum (input for the damper).

What is the source of the 8 kHz oscillations?

Magnetic frequency response of High-Luminosity Large Hadron Collider beam screens

M. Morrone,^{1,2,*} M. Martino,¹ R. De Maria,¹ M. Fitterer,³ and C. Garion¹

(a) LHC Main Dipoles at 20 K

- A 8 kHz oscillation is expected to be significantly attenuated by the vacuum chamber.

What is the source of the 8 kHz oscillations?

- **Still not clear**: the **present hypothesis** is that it could be related first unstable mode of the resistive wall coupled-bunch instability (frev-Q). See [1-3].
- Following this hypothesis the 8 kHz cluster of tones is an interplay between noise from the main bends circuit, impedance (resistive wall) and damper.
- **Multi-bunch simulations with noise, impedance, damper are still needed to verify it.**

Projections for dipolar perturbations in HL-LHC

7 TeV, $I_{OCT} = -300$ A, $\epsilon_n = 2.5$ μm rad, (62.315, 60.320), $Q' = 15$,
 $I = 1.2 \times 10^{11}$, $\beta^* = 15$ cm, Dipolar noise at BPMCS.7L4.B1

- Assuming a **lumped dipolar perturbation** in the ADT PU in Q7.
- Simulations shows that **0.1 μm** level of excitation **can degrade the machine DA.**

From dipolar to quadrupolar noise: the Inner Triplet simulations for HL-LHC

Inner Triplet: Voltage-control regime

- Based on previous studies [4], scan **individual frequencies** for **different strengths** in order to determine where **reduction of DA** is observed.
- Compare with PC specifications [5].

Approximations:

- Impact from beam screen, cold bore **not included**.
- Inductance** considered **constant vs f**.
- Impact from **individual frequencies**, not multiple harmonics.

Simulation parameters

HLLHC.v13
$\epsilon_n = 2.5 \mu\text{m rad}$
$I = -300 \text{ A}$
$(Q_x, Q_y) = (62.31, 60.32)$

7 TeV
$I = 1.2e11$
$\theta_{\text{crossing}} = 250 \mu\text{rad}$
$V_{\text{RF}} = 16 \text{ MV}$
$\Delta p/p = 25.78e-5$

 $Q_p = 15$, $I = 1.2e11$, $\beta^* = 15$ cm, $\beta' = 15$ cm, $Q' = 15$ cm, $\nu_{RF} = 4008$ MHz, $\nu_{RF} \cdot Q_p = 25.78e-5$, 49 angles
 and left of IP1 & IP5

- Frequency scan as a function of Q_x and Q_y for all circuits of IP1 & IP5. Each point is an individual study
- Conservative approach: same phase of noise in all locations. Switching frequency of the 18 kA circuit will be at 50-200 kHz.

Conclusions

➤ Dipolar excitation:

- Harmonics of 50 Hz have been observed in the beam spectrum. 2 regimes have been identified: **the low** (up to 3.6 kHz) and **high** (7-8 kHz) frequency cluster.
- Both regimes are the result of a **real beam excitation**. A correlation of the 8 power converters of the **Main Bends and the low frequency cluster** has been identified (larger impact on **B1H**). The **high** frequency cluster is not affected by the status of the Active Filters: the present hypothesis is that is due to an **interplay between noise, damper and impedance (first unstable couple bunch mode at 8 kHz)**.
- Simulations in the LHC with a realistic beam spectrum (lumped dipolar perturbation in a single location) indicate that these **harmonics lead to an increase of diffusion and can harm the beam lifetime**.
- **These harmonics will also be present in the HL-LHC and, assuming the same noise spectrum, the impact on DA is significant, especially due to the high frequency cluster.**

□ Quadrupolar excitation (Inner Triplet):

- Maximum output voltage is below the level where reduction of DA is expected.
- Switching frequencies are expected to be heavily attenuated and do not pose a limitation to the beam performance.

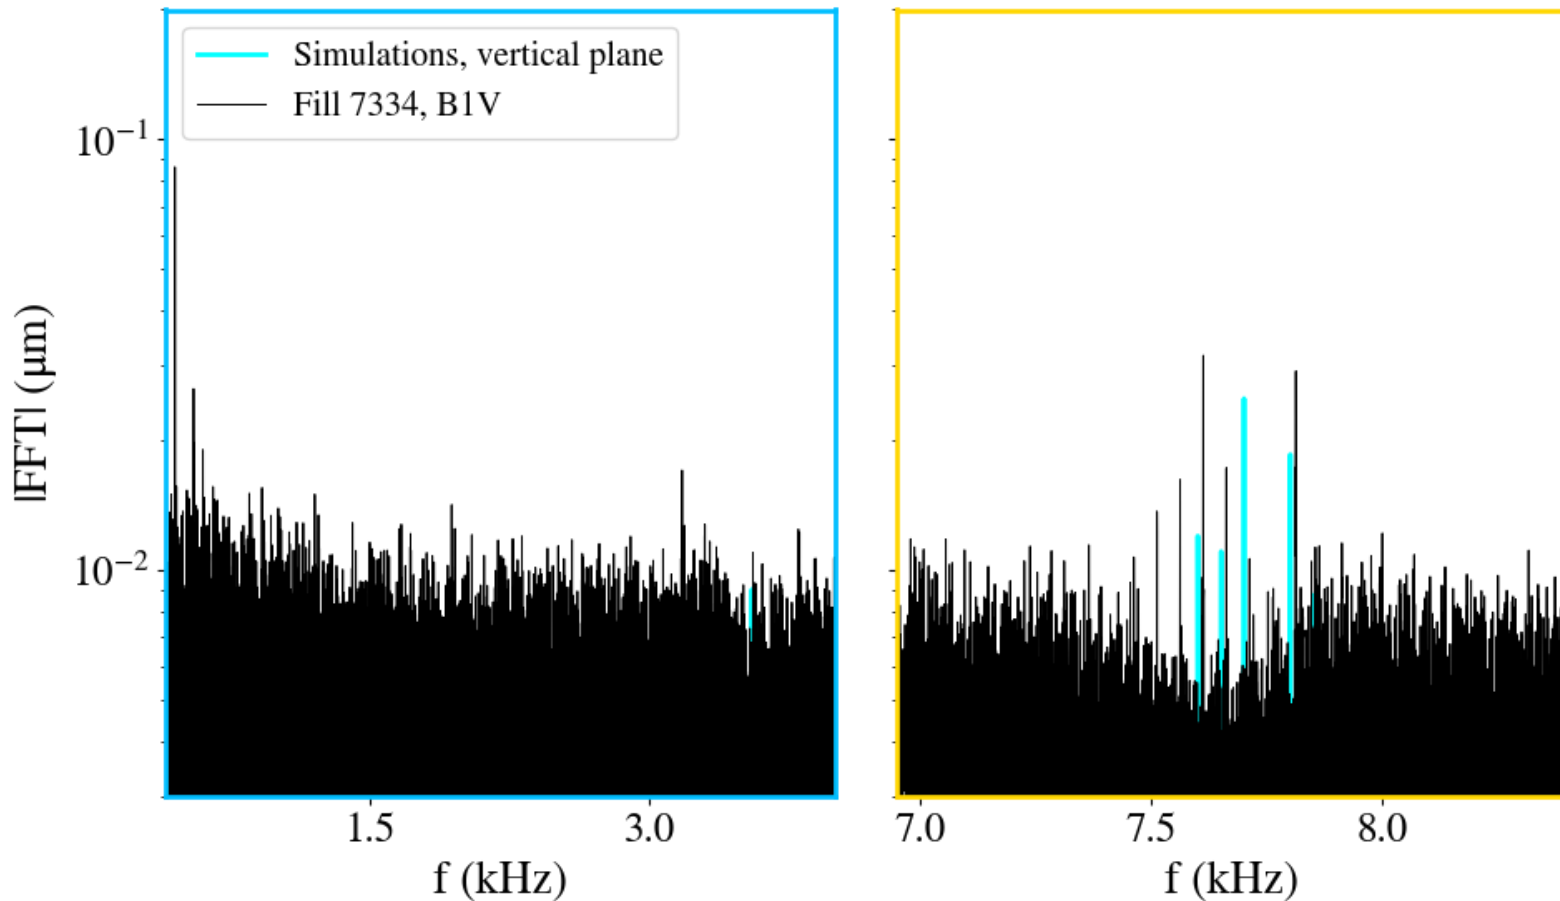

Thank you!

Backup

Coupling of H/V plane in simulation

- Vertical motion observed in simulations.

Are these tones an artefact? **No.**

- For **lower frequencies** (<4 kHz) impact of the IP1/IP5 phase advance.
