Abstract

Inertial Confinement Fusion is a promising option to provide massive, clean, and affordable energy for mankind in the future. The present status of research and development is hindered by hydrodynamical instabilities occurring at the intense compression of the target fuel by energetic laser beams. A recent patent combines advances in two fields: Detonations in relativistic fluid dynamics (RFD) and radiative energy deposition by plasmonic nano-shells. The initial compression of the target pellet can be decreased, not to reach the Rayleigh-Taylor or other instabilities, and rapid volume ignition can be achieved by a final and more energetic laser pulse, which can be as short as the penetration time of the light across the pellet. The reflectivity of the target can be made negligible as in the present direct drive and indirect drive experiments, and the absorptivity can be increased by one or two orders of magnitude by plasmonic nano-shells embedded in the target fuel. Thus, higher ignition temperature and radiation dominated dynamics can be achieved with the limited initial compression. Here, we propose that a short final light pulse can heat the target so that most of the interior will reach the ignition temperature simultaneously based on the results of RFD. This makes the development of any kind of instability impossible, which would prevent complete ignition of the target.

Burning of Quark Gluon Plasma in Relativistic, Radiation Dominated Systems according to Relativistic Fluid Dynamics

Applications to Pellet Fusion

Classical Fluid Dynamics (CFD) does assumes that all dynamical processes, including shocks and detonations, are having speeds slower than the speed of light, c.

Initial Relativistic FD (RFD) maintained this assumption based on the requirement of causality [A.Taub, 1948]. \rightarrow Engineering books keep this assumption even today!

Relativistic Heavy Ion Physics proved the opposite!

[A.H. Taub (1948)]

Relativistic Rankine-Hugoniot Equations

A. H. TAUB

University of Illinois, Urbana, Illinois and Institute for Advanced Study, Princeton University, Princeton, New Jersey*

Next we suppose that the three-dimensional volume is a shell of thickness ϵ enclosing a surface of discontinuity \sum whose three-dimensional normal vector is Λ_i . If we choose our coordinate system so that the discontinuity is at rest, then since

$$\lambda_{\alpha}\lambda^{\alpha}=1, \quad \sum_{i=1}^{3}\Lambda_{i}^{2}=1,$$

we have

$$\lambda_i = \Lambda_i$$
 and $\lambda_4 = 0$.

Hence Eqs. (7.1) and (7.2) become, as ϵ goes to zero,

$$[\rho^0 u^i \Lambda_i] = 0, \qquad (7.3)$$

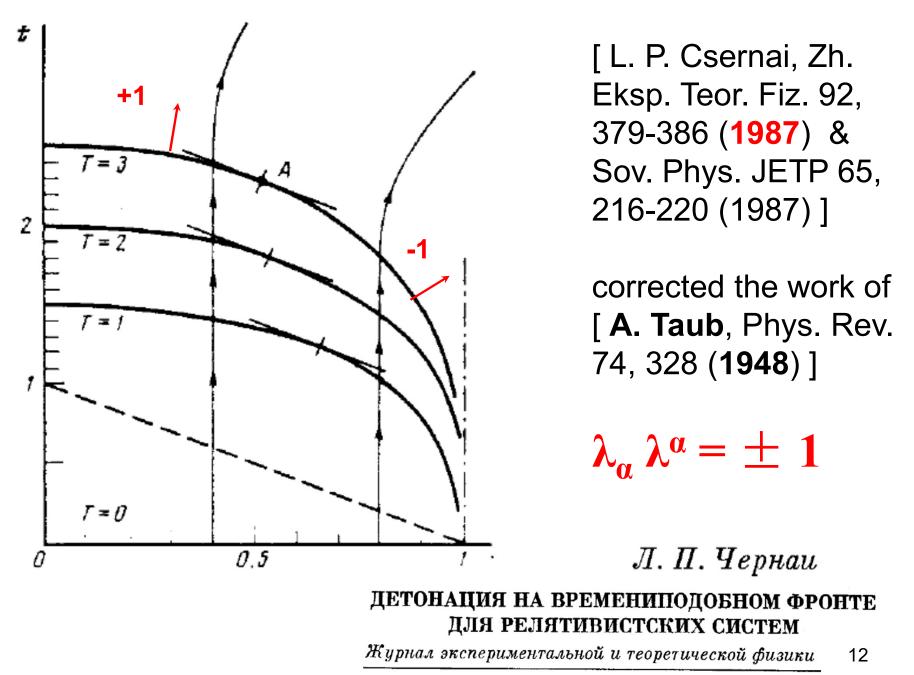

$$[T^{\alpha i}\Lambda_i] = 0, \qquad (7.4)$$

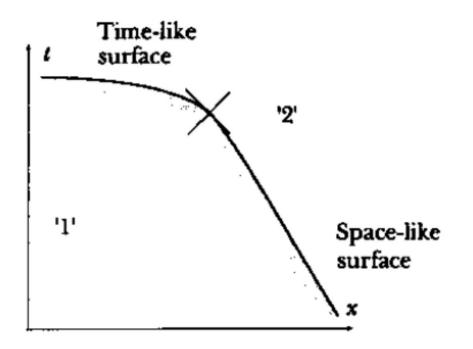

where

 $[f] = f_+ - f_-$

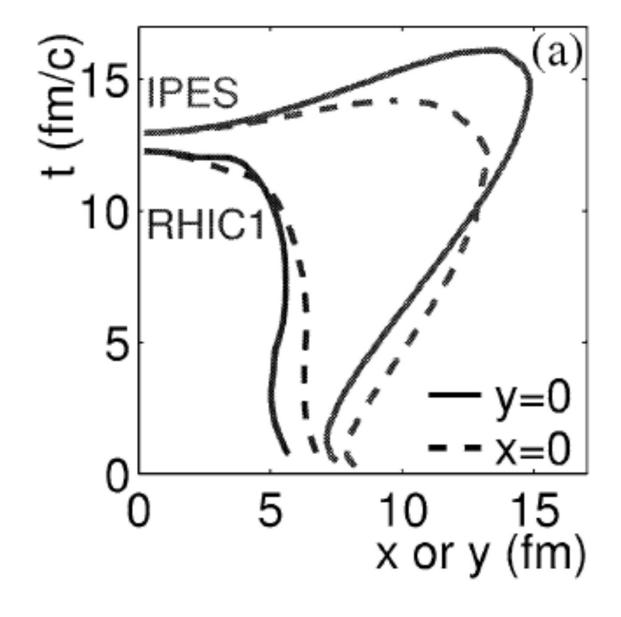

Taub assumed that (physically) only slow space-like shocks or discontinuities may occur (with space-like normal, $\lambda_4=0$).

This was then taken as standard, since then (e.g. LL 1954-)

Applications to Pellet Fusion

Relativistic Heavy Ion Physics proves that simultaneous ignition and burning is possible, both theoretically and experimentally!

Up to now all theoretical studies of Internal Confinement fusion are based on Classical Fluid Dynamics (CFD) [HYDRA, LASNEX]

Still the aim is to

- achieve Volume Ignition
- achieve Rapid Ignition
- but within CFD ?! \rightarrow

[L.P. Csernai & D.D. Strottman, Laser and Particle Beams 33, 279 (2015).]

Fusion reaction

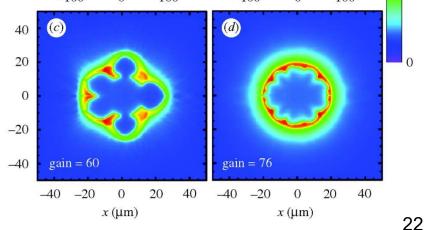

D + T → n(14.1 MeV) + 4He (3.5 MeV)

Constant absorptivity, Spherical irradiation Ignition temperature = T1 \rightarrow

Simultaneous, volume ignition up to 0.5 R (i.e. **12%** of the volume).

y (µm)

Can we achieve better volume ignition, and how?

Two ideas are combined by L.P. Csernai, N. Kroo, I. Papp [Patent # P1700278/3](*)

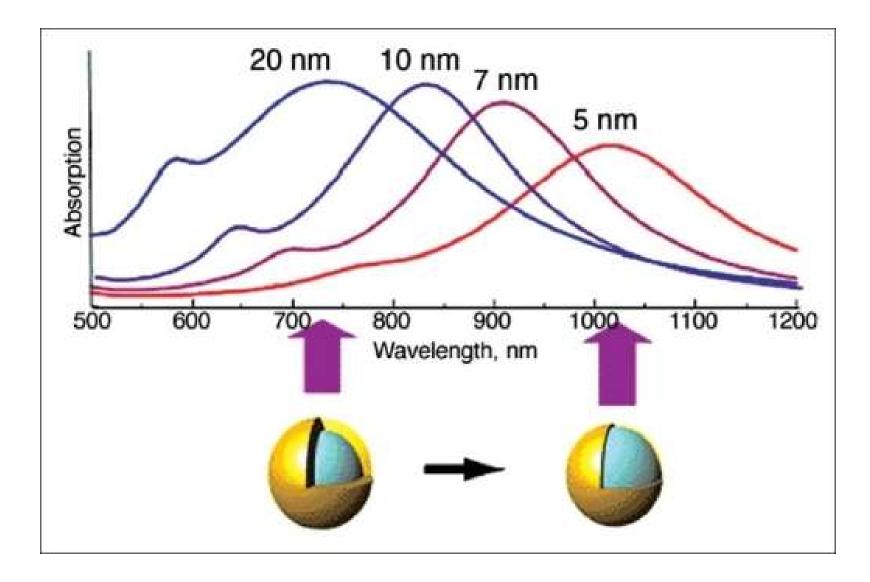

- Heat the system uniformly by radiation with RFD
- Achieve uniform heating by Nano-Technology

Mechanical compression and adiabatic heating should be reduced, because it is slow and leads to Rayleigh-Taylor instabilities. Similarly outside ablator surface should be reduced also.

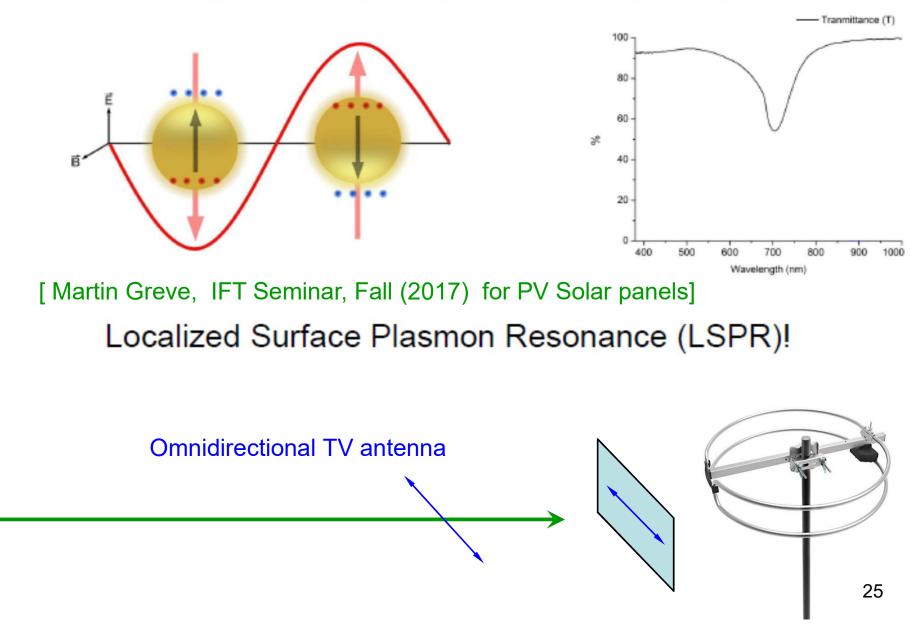

Uniform, 4π radiation should heat the target to ignition within the light penetration time (i.e. ~ 10-20 ps). This follows from RFD!

[L.P. Csernai, N. Kroo, I. Papp, *Laser and Particle Beams*, LPB, 36(2), (2018) 171-178. . https://doi.org/10.1017/S0263034618000149]

Variation of absorptivity by Nanotechnology

golden nano-shells enables

us to achieve the desired

variable absorptivity

(Tanabe, 2016).

Doping INF pellets with

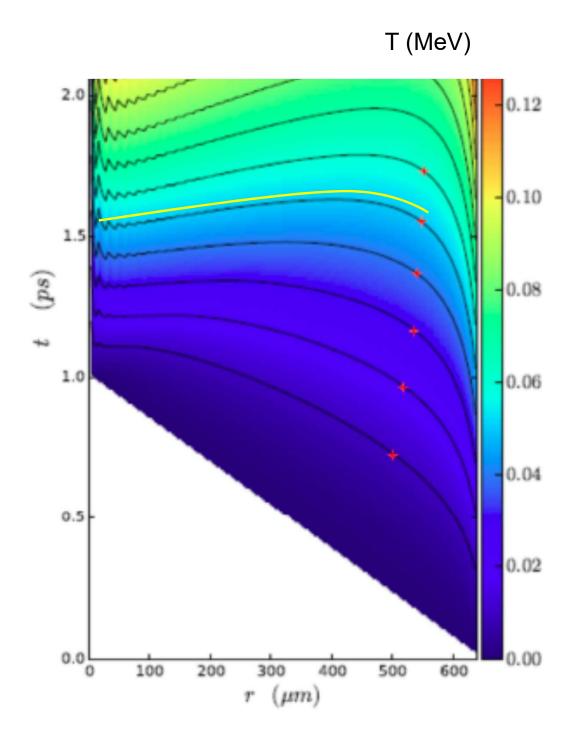

$$\alpha_k = \alpha_{k0} + \alpha_{\rm ns} , \qquad (12)$$

where the absorptivity of nano-shells, α_{ns} , is

$$\alpha_{\rm ns} = \rho G Q_{\rm abs}. \tag{13}$$

For a nano-shell of R = 30 nm the additional contribution would be $\rho G Q_{abs} = \rho Q_{abs} \ 0.283 \text{ cm}^2$. Consequently, for a typical nanoshell density (James *et al.*, 2007) of $\rho = 10^{11}/\text{cm}^3$ and a $Q_{abs} \approx$ 10, we can reach an additional absorptivity of

$$\alpha_{\rm ns} = 28.3 \,\rm cm^{-1}. \tag{14}$$

The absorption coefficient is **linearly** changing with the radius: In the center,

r = 0, $\alpha_{\rm K}$ = 30 cm⁻¹ while at the outside edge $\alpha_{\rm K}$ = 8 cm⁻¹.

The temperature is measured in units of $T_1 = 272$ keV, and T_n = n T_1 .

Simultaneous, volume ignition is up to 0.9 R, so **73% of the fuel target!** 27

Problem:

Not easy to realize, 4π irradiation geometry \rightarrow 80-192 laser beams

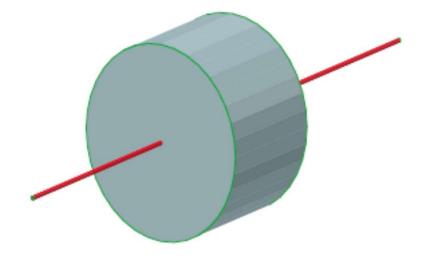

In the earlier estimates we did establish that:

- The principle of simultaneous volume ignition is theoretically possible with nano-shells
- We **did not** estimate the necessary laser energy need, and assuming extremely large laser input energy we neglected the losses.

- However the basic principle, the simultaneous all volume ignition can be achieved in 3D, 2D and 1D geometry also !!! (Einstein's synchronization of watches.)
- We did calculate the realistic energy balance
- → So, we repeated realistic estimates in 1D with a flat (coin like) target.

Thick Coin like target - New Developments L.P. Csernai, N. Kroo, I. Papp

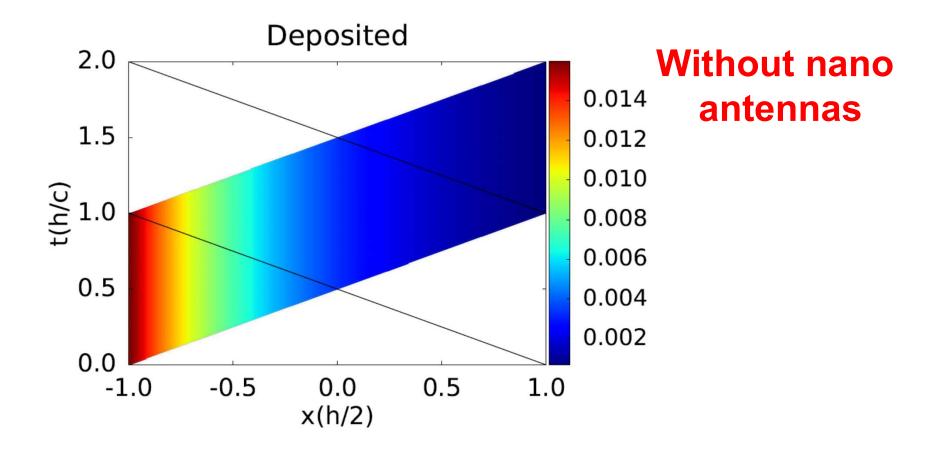

Thickness of the target is: *h*

h depends on pulse energy, ignition energy, target mass, ...

Figure 1: (color online) The target still should be compact to minimize the surface effects. The irradiation is performed along the x-axis from both sides towards the target. The laser beam should be uniform hitting the whole face of the coin shaped target.

X

The deposited energy from laser irradiation from one side only. The absorption is constant, this leads to an exponentially decreasing energy deposition, and only a negligibly small energy reaches the opposite end of the target.

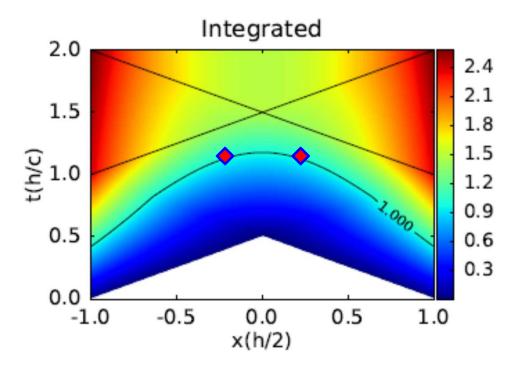

Figure 4: (color online) Integrated energy up to a given time in the space-time across the depth, h, of the flat target. The color code indicates the temperature, T, reached in a given spacetime point, in units of the critical temperature, (T_c) . The contour line T = 1, indicates the critical temperature, T_c , where the phase transition or the ignition in the target is reached. This contour line, compared to the one in Fig. 3, is never constant in time, indicating no simultaneous whole volume transition or ignition. The time-like (causally unconnected) part of the transition takes place only in the central $\sim 15\%$ of the target volume. The two straight lines indicate the light-cones originating at the outside edges of the target at the ending of the irradiation pulse.

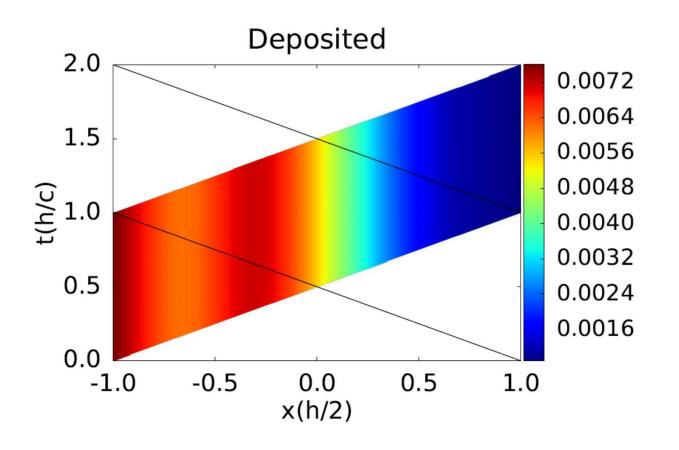

Without nano antennas

Irradiation from both sides.

Exponential decrease of deposited energy. Due to the already deposited energy, less energy reaches the middle →

The front and back surface is heated up but the middle is not!

Pulse length is: $t_P = h/c$

With nano antennas

The absorptivity is increased towards the center, due to the implanted nano antennas.

The deposited energy from laser irradiation from one side only. The absorption is modified by nano antennas so that the absorptivity is increasing towards the middle, so that the deposited energy is constant up to the middle. Then the absorptivity is decreasing, but hardly any energy is left in the irradiation front. Thus again only a negligibly small energy reaches the opposite end of the target.

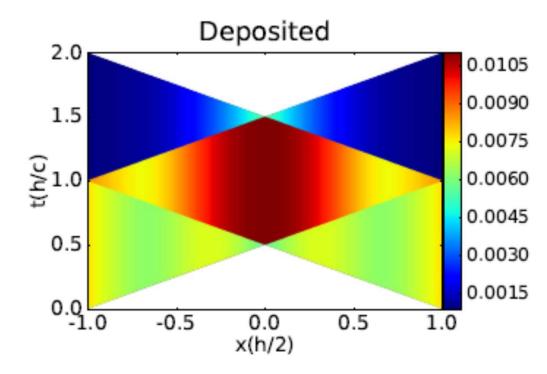

Figure 2: (color online) Deposited energy per unit time in the space-time across the depth, h, of the flat target. The time is measured in units of (h/c), where c is the speed of light in the material of the target. The irradiation lasts for a period of $\Delta t = h/c$ the time needed to cross the target. The irradiated energy during this time period is Q from one side, so it is 2Q from both sides together.

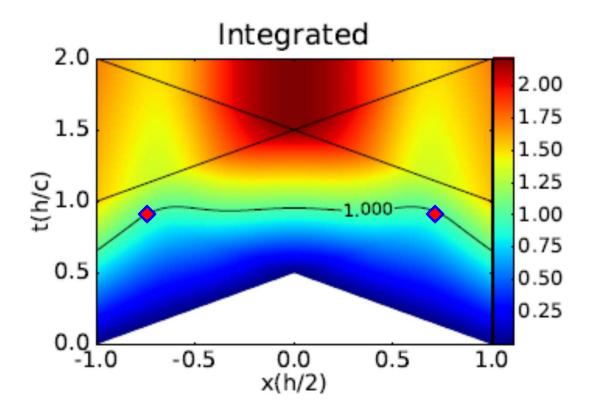

The color code indicates the deposited energy per unit time and unit cross section (a.u.). The deposited length is $\Delta x = c\Delta t$. Note! The absorptivity in this case $\alpha_K \neq \text{const.}$ For more details please see Appendix B.

With nano antennas

Irradiation from both sides.

Ignition energy is: Q_i/m e.g. for DT target: $Q_i/m = 27 \text{ kJ/g}$ \rightarrow if we have Q = 100 J, then we can have a target mass: $m_{DT} = Q/Q_i \text{ g} = 3.703 \text{ mg.}$

Then with m_{DT} and ρ_{DT} given we get the DT-target's volume, V_{DT} and $h_{DT} = 2.67 \text{ mm}$.

With nano antennas

Ignition is reached at contour line Q = I.

Figure 3: (color online) Integrated energy up to a given time in the space-time across the depth, h, of the flat target. The color code indicates the temperature, T, reached in a given spacetime point, in units of the critical temperature, (T_c) . The contour line T = 1, indicates the critical temperature, T_c where the phase transition or the ignition in the target is reached. This contour line is almost at a constant time, indicating simultaneous whole volume transition or ignition. The irradiated energy, Q is chosen so that, 1Q irradiation will achieve the critical temperature.

Test of principles with smaller pulse energy

1 Relativistic time-like (simultaneous) ignition

2 Using nano antennas to reach whole volume uniform ignition or transition 3 Using 1D geometry, with two beams from opposite direction for realizability

Let us take a P = 30 mJ, 1 ps laser, a polilactic acid (PLA) target with T = 150 C melting temperature, $Q_i/m = 28 \text{ J/g}$ this leads to $m_i = 0.32 \text{ mg}$ target mass, and $h_i = 683 \mu \text{m}$ target thickness.

The melting transition profile can be checked by simple and affordable analysis by microscope.

The distribution, and absorption properties of implanted nano antennas can be well optimized.

Thus, ultra-relativistic heavy ion physics lead to discovery Quark Gluon Plasma (QGP), but also to advances in (i) relativistic fluid dynamics (RFD).

With (ii) nano technology this may revolutionize in a simple, and (iii) affordable 1D geometry the technological development of (→ iv) Inertial Confinement Fusion.

This methodology may be used to study other dynamical, radiation dominated processes.
